But again writing under Pruning—but referring specially to cocoa—he says: "The cacao planter will have to give careful attention to the pruning of the trees if he wishes to get large crops. As the pods are borne on the larger branches the principle is to develop such branches by judicious pruning and to see that they are not covered up by a mass of foliage and small twigs. A typical cacao tree should have one stem giving off at a few feet from the ground three to five branches which spread in an open manner and are free from leaves except at the tops—thus the leaves shade the open interior portion without interfering with a free circulation of air. If the young plants throw out more than one main stem, the surplus ones must be pruned off; and after the lateral branches are formed, no upward prolongation of the stem must be allowed to grow. If the tree be left alone, these upward branches will come off from the stem just below the laterals in the form of suckers, and to leave them on is to cause the strength to be taken off from these

fruitful laterals as well as to allow the tree to run up, perhaps, for thirty feet or more, thereby causing much trouble in picking the pods. When the suckers are pruned off fresh ones will grow after a short time, so that the trees will require frequent attention until they are mature, when the tendency to throw out suckers will be stopped.

Among cocoa planters in Ceylon there may be said to have been two schools,—those who believed in pruning, and particularly suckering, and those who did not. The merits of the system of culture which each school practised were sought to be gauged by the bulk of crop which resulted in each case, and it is still perhaps a debateable point which gave the larger produce. But of late there has been a new and unexpected solution to the differences of opinion as regards the treatment of suckers, worked out by the unfortunate malady, affecting cacao trees in certain districts, called by experts "the cacao canker." We will not weary our readers by summarising the large mass of correspondence on the subject of this disease in cacao and its relation to the treatment of the suckers on the trees, but suffice it to say that the tendency on the part of those who had studied the subject and took part in the discussion has been to condemn such a mode of treatment as that which Dr. Nicholls advises in his *Tropical Agriculture* from which we have quoted. We do not believe that any one who has been moving about the cacao districts and comparing the condition of the two types of estates representing the two schools of cacao planters, will persist in the treatment which favours pruning and suckering. The question which remains to be solved is "what reason can be assigned for the failure in Ceylon of a system of treatment which is considered to suit the cocoa plant in the West Indies?"

OCCASIONAL NOTES.

We have to acknowledge with thanks receipt of the first two Circulars or Bulletins issued by the Director of the Royal Botanic Gardens, Peradeniya, and we have no doubt, to judge from the character of these two, that the Circulars will prove of inestimable value to all who are interested directly or indirectly in the cultural industries of the Colony.

We are glad to be able to state that through a kind concession granted by the General Manager of Railways it will be possible for the students of the School of Agriculture to be taken on periodical tours in connection with their work.

In India the occurrence of serious or epidemic disease among cattle has to be reported direct, and if necessary by telegram to the Veterinary Department. This is a plan that should be followed in Ceylon, as in many cases outbreaks of cattle murrain are found to have died out before the arrival of veterinary aid.

Mr. J. F. Bailey writing about the Papaw (*Carica papaya*) gives some interesting information about this familiar tropical fruit, in the last *Queensland Agricultural Journal*. The generic name is said to have been given to it

on account of the foliage somewhat resembling that of the common fig (*Ficus carica*); while Rumphius suspected that it was originally brought from a district called Popaya in Peru, and hence that name came to be applied to it.

The Papaw Juice—which is now quoted at 5s. per lb.—is easily prepared. The unripe fruit has to be scoured or lined some $\frac{1}{4}$ in. deep, with a sharp knife daily, and the juice caught and dried upon sheets of glass, when it becomes at once a marketable commodity. The active principle, papain, is in much esteem as a medicinal agent. The *Chemist and Druggist* gives the following method of preparing it:—"The juice is pressed out of the fruit, clarified by filtration through a twill bag, and the ferment precipitated by alcohol. It is then dried but is sometimes purified by treatment with water."

The subject of rainfall has been much before the public of late, no doubt due to the furnishing of departmental rainfall returns and to the occurrence of some unusually heavy falls in the country. In this connection the following quotation will be found interesting: "Many local circumstances may affect the quantity of rain which falls in different countries; but, other things being equal, most rain falls in hot climates, for there the vaporisation is most abundant. The rainfall decreases in fact from the equator to the poles. At London it is 23.5 in.; at Bordeaux it is 25.8; at Madeira 27.7; Havannah 91.2; and at St. Domingo 107.6. The quantity varies with the season: In Paris, in winter, it is 4.2 in.; in spring 6.9; in summer 6.3; in autumn 4.8 inches. The heaviest rainfall at any place on the globe is on the Khasia Hills in Bengal, where it is 600 in., of which 500 in. fall in, seven months. The driest recorded place in England is Lincoln, where the mean rainfall is 20 in., and the wettest is Styne in Cumberland where it amounts to 165 in." This was written in 1877, and it would be interesting to know what changes have taken place since then.

THE KAPOK TREE.

This tree, botanically known as *Eriodendron infractuosum*, the floss from which is commonly known among the natives of Ceylon as "pulun," is the subject of a notice in the *Imperial Institute Journal*.

In the course of a description of the various uses of the tree, we find it stated that "the seeds are sometimes eaten; they yield a bland fatty oil, the residual cake being used as a cattle food." Such a statement would more correctly apply to the seeds of the true cotton (*Gossypium*), for to say that the cake or poonac is used as cattle food would convey the idea that such use is general or even common, while on the contrary it must be rare. Dr. Watt himself does not write very definitely regarding the uses to which the seeds are put. He says:—"The seeds are said to be eaten.....the seed cake is sometimes given as fodder." As regards Ceylon, it may be said that the seeds are used as food neither for man or beast.

Some time ago we were consulted as to the desirability of using the seeds of kapok for manurial purposes. The inquiry came from a

large dealer in the "silk cotton," who having to deliver the cotton clean naturally had large quantities of the seed on his hands. The following is a comparative analysis of the cake of Kapok and cotton.

	Kapok.	Cotton.
Water	13.28	12.00
Nitrogenous matter; albuminous compounds	26.34	20.62
Fat	5.82	6.36
Non-nitrogenous extraction	19.92	35.42
Woody fibre	28.12	20.36
Ash	6.52	5.64

"The ash of the kapok seed," we are told "contains 28.5 % of phosphoric acid, and 24.6 % of potash; it ought, therefore, to be of value as a manure."

The great partiality which rats and mice have for the seed (destroying pillows and mattresses, as they do, to get at the few seed that may have been left in the floss in cleaning) would seem to indicate the possibility of utilizing it as a stock food, at any rate in the rural districts, for feeding, ploughing and draught cattle.

As regards the floss we quote as follows from the *Imperial Institute Journal*:—

Serious complaint is made in Australia and elsewhere of the quality of the kapok shipped from India. "Even at the low price of India kapok (about 3d. per lb.) it is found better to pay 8½d. or more per lb., for kapok grown in Java. The former is frequently received in such a filthy condition as to be almost unsaleable." The hydraulic or steam-press packing of kapok tends to destroy that peculiar elasticity to which it owes its value. In addition, the packing tends to express a dark-coloured oil from the seeds left attached to the fibre, and hence a noticeable difference in colour between the Indian and the beautifully white Java products.

At Java the trade has assumed a uniform practice. No unclean stuff is shipped, but the different grades of cleaning denote standards of quality; the first, "extra cleaned," is the first picking of the crop, and is cleaned by machinery; the second, denoted as "best cleaned picked," being all hand-picked and free from seeds, except an odd one here and there; the third, is simply designated "cleaned." It contains a few seeds, together with the "slubs," or little knotty curly lumps, which are cast aside from the higher grades. Packing is all done in straw mats, and the floss is never tightly pressed.

The silk-cotton tree also grows in the West Indies, but for all practical purposes it is counted of little value. Considerable difficulty was at first experienced in the importation of silk-cotton, owing to its great bulk and the heavy cost of transport, but this has been overcome by a silk-cotton press constructed by Stork & Company, at Henglo.

In the annual report of the Director of the Botanical Department, Jamaica, 1884, the following remarks occur:—

"It now only remains for some enterprising firm to initiate the collecting of silk cotton in Jamaica, and to ship it in well-packed bales for the European market. If each cotton tree yielded at the rate of about 100 lb. weight of clean floss, there might be exported from Jamaica every year

about 3,000 bales of silk-cotton of the value of £9,000."

"In Ceylon kapok is collected throughout the villages of the interior. The season commences in May, and one crop is obtained each year; the tree reaches maturity about the fifth year."

Australia receives large shipments of kapok both from India and Java, but it is difficult to obtain reliable statistics concerning the trade. It is entered at the local Customs under all manner of names, such as "vegetable fibre," "vegetable wool," "silk-cotton," "tree cotton," "raw cotton," and "small cotton."

So much attention is kapok receiving in the East Indies, that the cultivation of the trees is even said to be ousting coffee in the province of Bu ma. Kapok has not been received in England on a very large scale; 100 bales a month are sent from India and Ceylon (1 bale = 200 lb. Ceylon, 400 lb. Indian), and the price varies from 2½d. to 4d. per lb.

We recall a letter addressed by Messrs. Thirkell & Co., dated London, 24th May, 1895, to the *Ceylon Observer*, in which that firm stated that "kapok is wanted in fairly clean condition at 4d. per lb., and that a demand seems to be springing up for the silky floss of *Calotropis gigantea*—Mudar, or, as it known by the Sinhalese, Wara.

We note that the *Indian Forester* in taking over the article on kapok states that "kapok" is a Dutch name, whereas the word is undoubtedly of Malayan origin.

THE VITALITY AND DISSEMINATION OF SEEDS.

This is a subject upon which Mr. W. W. Glenny of Barking, Essex, contributes an interesting paper to the last volume of the Journal of the Royal Agricultural Society, England; a subject which he rightly terms a comprehensive one, but of great charm and value to the botanist, the horticulturist, the farmer, and even the general observer. The paper referred to is comparatively exhaustive, and we can therefore touch upon its most interesting points.

It is a common experience that ground disturbed below the average depth of cultivation, where fresh soil is brought to the surface soon becomes covered with varied and promiscuous vegetation. Plants unknown in the immediate locality greet the eye, and curiosity is aroused by the appearance of these strange visitants. Various theories are rife to account for the presence of such additions to the flora of the immediate district. Where do these abnormal specimens spring from? Prof. Balfour says that seeds, when buried deep in the soil, lie dormant for a long time, and only germinate when the air is admitted by the process of subsoil ploughing or other agricultural operations. As instances he mentions the springing up of white clover and other plants which had previously not been seen in the locality, when land is turned up for the first time, and refers to the growth of strange plants after the great fire of London, a phenomenon similar to that which follows the burning of forests and draining of marshes.

Mr. Dureau de Mallé enunciated a distinct and unique theory regarding this question: He calls it alternative succession, and held that, as good husbandmen provide for a rotation of crops, in like manner nature arranges that indigenous species follow each other of their own accord. He cited many instances of one kind of growth, when cut or burnt down, being followed by a totally different form of vegetation. Similarly Herne says that straws berries grow in great quantity where fire has passed over a country, and Du. Petil Thomas that whenever forests were destroyed in the Isle of France, the soil was instantly covered with alien species indigenous to Madagascar, while Buck, Mackenzie, Davies, and Darwin and others mention many strange cases which we need not quote here, in proof of the occurrence of what may be called a natural system of rotation of crops. Mr. Holt White asserts that the application of certain substances will cause seeds to gemminate that would otherwise lie dormant. Lime, he says, will produce white clover in some soils; furze if sown on a newly-made bank will rarely grow, but put a little gritty sand on the seed and it will certainly vegetate. In most of the Essex marshes, whenever a new ditch is dug, brown mustard will spring up, although it has not been seen before in the memory of man. Of Camomile it is said that it has been observed to spring up on the site of habitations, sometimes marking precisely the ground plan of the building. Miller records the springing up of the fumitory plant in a spot where the seeds had lain dormant for fourteen years.

All this, though not absolutely supporting M. de la Malle's theory teaches that seeds of certain plants will remain uninjured in the soil for an indefinite time, provided the conditions are such as to hinder germination.

Materials such as sweepings from warehouses, docks, cowhouses and stables, manure and dust from ships coming from foreign lands, pulp from jam factories, are some of the sources whence strange specimens arrive. Here are a few instances: the troops summoned from Algeria to France in 1870, disseminated by fodder and otherwise a number of African and southern species which excited wonder. Many foreign and colonial plants are seen for a season where the sweepings of the warehouses are deposited near London. It is amusing to contemplate a field of oranges in Essex, yet where the pulp from Keiller's Marmalade factory was distributed over the land with manure, thousands of young orange plants were noticed.

Wind, water and animals are also instrumental in disseminating plants; many seeds and fruits with winged and feathery appendages are easily wafted about, others are carried by rivers and streams, and some can be transported by the ocean current to a great distance with their germinating power unimpaired.

Seed-eating birds are, as a rule, not the seed-planters; seeds which convey nourishment are eaten, and in the process are ground and destroyed; seeds which are imbedded in nourishment are swallowed and survive. It has been discovered that American crows can take in and retain for some

time and finally disgorge at will anything distasteful or injurious. Hence, having swallowed berries and assimilated the pulpy part, they can eject by the mouth clean and polished seeds. Some seeds may also through the alimentary canal of the carrier travel far away into other provinces, countries or continents. Many birds go a long way for their daily food, whilst migrants cross whole kingdoms at recurrent seasons. A great number of birds traverse a considerable distance in a minute; they are thus able to carry into foreign countries in a short time the plants or vegetables on which they feed.

Sig. Pistoni of Messina, a patient observer, gives instances of birds disseminating the bulbs of a species of *oxalis*, bringing over two varieties of oak into Sicily and Sardinia and *Acacias* from Massowah and Australia. In Sicily, where quails abound, the plan is to open the cup of birds directly they are killed, to obtain the varied seeds therein. These seeds are sown in pots, and strange and rare plants are often found.

We shall conclude our notice of this interesting paper in our next issue.

ARROWROOT AND THE CANNAS.

We are indebted for the facts in this article to a paper on the *Canna* which is published in the September number of the *Queensland Agricultural Journal*. We here deal mainly with the economic value of the *Cannas*, but the paper referred to should prove most interesting and instructive reading to gardeners.

Arrowroot is the product of species of *Maranta* and *Canna*.

The name *Canna* is said to be derived from an old Carib name of the plant; *Maranta* from Bartholomew Maranta, a physician of Venosa, who died in 1559. It was bestowed in his honour by the botanist Plumier.

Maranta aurundinaceae, and probably one or two other species, yield that which is known as West Indian or Bermuda arrowroot. The name arrowroot is usually supposed to be derived from the fact that the Indians used the bruised rhizomes as an antidotal application to the wounds from poisoned arrows, but some authorities contend that the word comes from "Aru-Aru," the name which the Aruac Indians of South America give to the farina obtained for the manioc. *Tous-les-mois*, another form of arrowroot, is produced in St. Kitt's and other West India Islands from the underground stems of *Canna edulis*, and possibly other species. The name *Tous-les-mois* is said to be derived from Touloula, which is a Carib designation for *Canna*. It is also said to be given in consequence of the plant flowering the whole year round. This is the variety of arrowroot produced in Queensland. It is in all respects as valuable and nutritious as the *Maranta* or West Indian arrowroot, being only a little darker in colour. Under the microscope it is very distinctive in character. The granules are very large, exceeding in size those of all other known starches. *Maranta* arrowroot, it should be mentioned, is the only kind recognised

under the Food and Drugs Act of Great Britain, and last year a dealer at Ashford, in Kent, was prosecuted for having sold Queensland arrowroot instead. It is interesting to find, however, that the case was dismissed on the ground that there was no intention to defraud, but the fact was pretty well established that Queensland arrowroot could only be sold in England under the distinctive name of Queensland arrowroot.

Efforts have been made to induce the cultivation of the *Maranta* plant instead of the *Canna edulis* for the production of arrowroot in Queensland. It is contended, however, that as a food product the *Tous-les-mois* is equal to or more valuable than the others, and the yield of the farina is very much greater per acre. Again, the *Maranta* roots much deeper than the *Canna edulis*, consequently requiring deeper and more expensive cultivation. For the same reason it is much more expensive to harvest.

From 1830 to 1860 attention was given to the *Cannas* chiefly as foliage plants, and cultivation and hybridisation was carried on with this purpose in view.

Since 1863 the value of the *Cannas* as flowering plants began to be recognised, and attention was directed to the raising of varieties of dwarfer growth, with brighter coloured flowers broader in the petal (or, correctly speaking, staminodia), thicker in texture, on finer and more massive spikes. The grower who has made the greatest advances in the production of the beautiful-flowered *Cannas* is M. Crozy, of Lyons, so thoroughly is he identified with our garden *Cannas* that he is said to be known in his own neighbourhood as "Papa Canna," a name given to one of his latest varieties.

The hard black round seeds of the *Cannas* are popularly known as Indian Shot, and they are reported to have been frequently used for shot in the West Indies. They have also been used as a substitute for coffee.

VETERINARY WORK IN CEYLON.

In my report for last year I suggested the formation of a staff of veterinary assistants stationed in various parts of the Island. In September last this was sanctioned by Government, and appointments were offered to Mr. W. A. de Silva and Mr. Hoole, Graduates of the Bombay Veterinary College, to be respectively stationed in the Northern and North-Central Provinces. Unfortunately Mr. Silva, from whom I felt certain of great assistance in the work, did not see his way to accept the appointment. Consequently, I was left with one assistant, Mr. Hoole, who is stationed at Anuradhapura.

Early in September Mr. Hoole took up his residence at Anuradhapura, and has been travelling most of the time since, as detailed in his reports furnished to Government. His work will certainly be difficult at first and disheartening, and must advance slowly step by step. He mentions that village headmen are not strict enough, and in the majority of cases do not take sufficient interest when an outbreak occurs, or even see that his instructions are carried out.

In some outbreaks, especially in the Western Province, when careful measures have been taken by headmen, disease has not spread further than the village in which it broke out.

The owners in most cases, especially in the Northern and North-Central Provinces, are poor and ignorant, and, what is worse, superstitious. A great many believe that disease is due to the displeasure of supernatural beings, and if they arrest the disease they will fall sick themselves. Others prefer to commit their cattle to the care of the gods sooner than carry out any sanitary or suppressive measures they do not know about or understand. Again, a large number of animals are semi-wild, and it is next to impossible to administer medicines or to do anything with them. These are a few of the difficulties encountered in dealing with outbreaks of disease.

It is very troublesome and expensive work in Europe to stamp out contagious and infectious diseases, where fences exist, the country is open, with a large police force and thoroughly organized Veterinary and Agricultural Departments and other things in favour of the work. In Ceylon, from the wooded nature of the country (hiding wild and domesticated animals dead of disease), seasons, impure water and scanty food, want of shelter, religious and superstitious beliefs, and indifference, the work is rendered extremely difficult. The headmen and people must first be made to understand the why and wherefore of such strict measures necessarily enforced, and that it is to their own advantage to try and prevent disease amongst their cattle; then I think they will take every precaution against disease. The Assistant Veterinary Surgeon's work must therefore at the outset be largely coupled with instruction upon management and hygienic and sanitary points.

A great deal rests with the headman of each village. If he would take precautions whenever a case of disease occurred, a large number of deaths might be prevented. As soon as a case comes under his notice of suspected cattle plague, he should at once remove it from all others and prevent any communication with it except by the person who is looking after it, or even kill it and bury it,—the deeper the better,—or burn it.

I have no doubt many cases are reported as murrain that are not murrain at all. In many cases reported the disease appears to be confined to buffaloes, black cattle escaping to a great extent.

True murrain does not pick and choose its victims, but spreads amongst all in contact. The buffaloes lay about in tanks and pass both dung and urine freely into the water. During the dry season, when the water becomes low, it is highly charged with these impurities, and from this alone there are many deaths from severe diarrhoea. Usually in dry seasons there is also great scarcity of food. The animals become weak and emaciated. Then when the rain comes and the young grass appears a great many are not able to stand the change, and die. It would be a good thing if some of the grass, &c., was dried in the sun and made into hay during the time when it is in plenty, and saved up for the cattle to eat during the dry season.

When cattle are sick they require very careful nursing. They lose appetite and will not eat

unless coaxed to do so by giving small quantities often of different foods. They also require gruel or congee of some kind until they regain their appetite. If they are not well attended to, the chances of recovery are minimized, and they have no strength left to support them during convalescence. It is with the greatest difficulty that owners can be persuaded to do this. They say they cannot afford it, and it is quite true. In some places I visited they were hardly able to get congee themselves. I am quite sure that if the cattle were well looked after, and given good food and water, there would be a great deal less disease reported.

In my report for last year I suggested that animals imported into the Island should be properly inspected before being allowed to land, in order to prevent as far as possible the introduction of any diseased animal or animals that have been in contact with diseased ones.

The number imported is considerable, as the following figures will indicate:—

		1895.		1896.
Colombo	{ Cattle	... 11,276	... 8,983	
	{ Horses	... —	... 832	
	{ Sheep and Goats	... —	... 68,201	
Mannar :	{ Cattle	... 4,764	... 4,934	
	{ Sheep and Goats	2,317	... 3,684	
	{ Horses	... 72	... 77	
Vankalai	{ Cattle	... 801	... 1,358	
	{ Sheep and Goats	8,613	... 4,096	
Pesalai	{ Horses	... 18	... 26	

I am now making arrangements to inspect the cattle daily.

The "tick plague," so prevalent in Australia, has been noticed in horses imported into India. Most of the imported cattle come from India, where, as is well known, there are frequent outbreaks of "rinderpest." The South African experience should be a warning to countries into which cattle are imported. It has been reported the outbreak of rinderpest there was due to importation of cattle from Aden.

Several cases of rabies have been reported by the Police. On March 28th a rabid dog bit another dog and a goat on the ear. The dogs were destroyed. The policeman cut off the goat's ear at once and it apparently suffered no ill-effects from the bite. On April 7th another case was reported from Bambalapiyiya, and a woman was bitten and placed under native treatment. On May 25th another case occurred, and the owner of the dog and two more dogs were bitten. The dogs were all destroyed. Probably there are many more cases than are reported. I saw two horses during the year that had been bitten on the nose by dogs suffering from rabies. One died showing well-marked symptoms of rabies, the other suffered no ill-effects.

A great many more of the unfortunate dogs seen about the town should be seized and destroyed. In nearly every street dogs are seen lying about covered with mange, whose life must be far from happy. Each valuable dog should be provided with a small collar, with a number upon it corresponding to the owner's name and address registered at the police station; the remainder should be seized and, if not soon claimed, destroyed.

I should like very much to see something done to prevent the branding of cattle with hot irons to such a great extent as is now practised. It is totally unnecessary, and nothing can be put forward to support it. Nobody can have any objection to branding a *small mark of ownership* upon the cattle, but the letters and name might be as small as possible instead of nearly covering the sides of the animal. The most unnecessary and cruel practice is covering the animal with the fantastic figures so commonly seen, especially on draught bulls. I have no doubt it is done with the belief that it improves, the health and condition of the animals, and I think a little persuasion from district officers and headmen would lessen the practice considerably.—*Colonial Veterinary Surgeon's Report for 1896.*

INVESTIGATIONS INTO RINDERPEST.

Dr. Kohlstock has forwarded an exhaustive report to the Secretary for Agriculture at the Cape, on the results obtained from the experiments which Dr. Koch had directed him to carry out in completion of his work. From this report, which we are unable to take over bodily, we make the following extracts:—

To prove how long immunisation produced by the inoculation of 100 cc. of serum obtained from a salted animal lasted, three beasts were injected. No. 1 received after 24 hours a fatal dose of rinderpest blood. No. 2 was heated similarly after 10 days. No. 3 after 20 days.

Nos. 1 and 2 were immune after a slight attack of rinderpest, and No. 3 died.

This tends to show that immunisation produced by serum is of short duration, not longer than 10 to 20 days.

The serum used in this experiment was of weak immunising power, and it would be well to repeat this with a more potent sample.

Experiments undertaken to ascertain the best period at which to bleed the animals for immunising serum have given the following results:—

Serum taken from a healthy full-grown animal after mild rinderpest, which had been inoculated with 20 cc. of virulent blood without effect to prove its immunity, has given the strongest serum. Twenty-four cattle were used for this experiment. These have been rendered immune either by inoculation with gall or serum.

The best serum was given by an animal which was first injected with gall and then was injected by rinderpest blood, after four days, and before immunity was established, so that it suffered from a mild attack of rinderpest.

This is the method recommended by Dr. Koch, and which I have established by further experiments.

I think that these also should be repeated. The serum is strongest when taken between the 10th and 20th day after the inoculation of 20 cc. of virulent blood, say the 15th day.

To raise the immunising power of the animal it would be advisable to inject higher doses than 20 cc. This has already been done, but the experiments are not yet concluded.

To ascertain if the mixture of one per cent. of virulent blood with immunising serum was capable of spreading the disease, I have rubbed the mixture in the nostrils, and introduced it into the nasal passages.

The animal did not become ill, but died after it was inoculated with virulent blood.

In this experiment only a weak serum was used, as this was the more likely to allow the animal to become infected. I wish the experiment to be repeated with a stronger serum, to see if it would be rendered immune.

With rinderpest gall the following experiments have been made:—

I may mention that previous to use all galls were tested microscopically and bacteriologically, since animals which died six or seven days after the injection of good gall had been previously infected by the accidents to which I referred at the beginning of this report.

Those which became immune were tested first with 0.2 cc. and then with 10 cc., and last with 20 cc. of virulent blood, and were unaffected thereby.

Animals which were injected either with brownish-green gall, containing the Simpson bacillus in pure culture, or gall of a brown colour, containing both bacteria and streptococci, became immune without the occurrence of any accidents such as abscesses, etc.

Thick green gall, free from smell and organisms, has often been taken from dead cattle. On one occasion I rendered an animal immune with such a fluid, which had previously been mixed with normal salt solution to render it thin enough to go through the needle by injecting 20 cc. of the mixture.

This is the only experiment of the kind yet made. The yellow-brown gall, with yellow flakes free from smell, taken from an animal which had been suffering 3 weeks from rinderpest, and died of the secondary infection, caused sickness in an animal on the 9th day and death on the 15th day. The gall if it did not cause the death of the animal certainly failed to render it immune.

It has frequently been stated that gall used while still warm is capable of infecting. I have injected an animal with 10 cc. of fresh warm brown gall which gave a yellow froth. The beast became immune and resisted the inoculation first with 2 cc. and then with 20 cc. of virulent blood.

To ascertain the period at which gall should be taken to give highest protection, a series of animals were injected and killed on the 5th, 6th, and 7th days of fever. Those killed on the 6th day gave the best results. Ten animals killed on the 6th day gave 750, 350, 470, 500 and 500 cc., total 2,570 of good dark green clear gall, without smell or organism, the others were useless. Thus 10 animals would have served to immunise 257 head of full-grown stock.

Gall kept in the ice box does not lose its power for some time; cattle have been immunised with gall kept 14 days in this way.

Several other experiments with a view to discussing methods of preserving gall are in progress, as it may often be necessary to send galls some distance.

* * * * *

Two calves born on the station proved to be immune; the first was produced by a cow which had been treated with serum. The young beast when one month old received with impunity sufficient rinderpest blood to kill a full-grown animal sixteen days after it was inoculated a second time with enough blood to kill 100, and then with enough blood to kill 1,000 oxen, it is strong and healthy notwithstanding.

The second or weakly animal similarly proved to be perfectly immune.

* * * * *

Upon the famous Talpan and Klippicspan, the 217 animals inoculated by Dr. Koch, Dr. Turner and myself are in perfect health, and the majority after 59 days and the rest after 39. I may remark that neither of these animals developed an abscess.

To obtain a clear proof how long the immunity lasts, I have inoculated with rinderpest blood sufficient to kill 100 animals on the farm Susanna, five of the beasts previously operated upon by Dr. Koch three months ago.

Two of these animals had been tested in this way by Dr. Koch himself, the other three had not been touched since the first inoculation with gall. All five animals are in good health, with normal temperatures after the lapse of eight days.

This shows that this immunity produced by gall continues at least three months.

My experiences gained on farms on which I have infected the cattle shows me that infection can easily be introduced into the herd by the very Kaffirs employed to cast the animals for the purpose of the operation.

I can also see, too, that young calves and animals in poor condition are those most susceptible to the infection.

As regards the idea that rinderpest gall is capable of conveying the disease, I can assert that Dr. Koch used many galls of various kinds, and until the station became thoroughly infected failed to produce the disease in any animal.

At Klippicspan and Talpan wherever Dr. Koch, Dr. Turner and myself made arrangements which were strictly carried out no animals died from the injection, and I can only be responsible for inoculation performed under such conditions.

My recent experiences convince me that gall of a dark green colour clear, without smell, and which when shaken gives a white froth with greenish tinge, never gives rinderpest but confers immunity, and only such galls must be used for the purpose.

Even these should be examined microscopically and bacteriologically to prove them free from septic organisms.

I repeat that gall in sterilised air-tight bottles will preserve its power on ice for the space of at least fourteen days.

This has been tested. Therefore the gall is a practically useful immunising agent.

In fact gall properly chosen and used with all scientific precautions cannot produce the disease.

I am sorry that it is impossible for me to experiment upon an undoubtedly clean herd, and can only recommend that this most urgently necessary experiment should be carried out without delay with 6 different galls collected on the 6th day as previously recommended, and tried upon 60 animals on a farm where rinderpest has never been and which is far away from any centre of infection.

The temperatures should be taken 4 days previous to the inoculation, and if they are normal the experiment should be made on the 5th day, and each lot of 10 animals inoculated with a different gall, and marked.

The persons casting the cattle must not have been engaged on infected farms.

The outside of the bottles containing the gall must be well disinfected; the cattle must be watched so that they can never incur any danger of infection until immunity has set in.

So far as I know such an experiment has never been tried before.

Should only one of these animals suffer from rinderpest, it then can be proved that good gall can convey the disease, a statement I shall dispute until thus tested.

If this last recommendation cannot be carried out, I advise that before beginning the infection the cattle should be divided into 3 lots.

The first lot should consist of strong full grown cattle.

The second sucking calves with their mothers.

The third lot weaned calves and old weak cows.

The temperatures should be taken, all suspicious cases isolated, and they should be inoculated with rinderpest gall on the 5th day.

This would determine whether the physical condition of the animal had any effect on the process of immunisation.

As regards the injection itself I would say that the cattle of lots 1 and 2 should all be injected with 10 cc. of gall except the calves, the latter should be inoculated 8 days later.

Cows heavy with calf should not be inoculated unless the operation can be performed without causing them accidental injury by casting, &c. Unless this can be assured the inoculation had better be postponed until after calving.

The third lot must be inoculated 8 days after lots 1 and 2, and the 5th and 7th days after inoculation the temperature should be taken and all those with fever must be isolated.

The 10th day after inoculation 2% should be taken out of each lot and infected with rinderpest blood.

Those full grown should receive 0.2 cc., calves 0.002 cc., the latter quantity is twice the lethal dose.

If the control animals are infected it will be proof that the gall has failed to immunise and the operation must be repeated.

I am certain that if gall inoculation is made in the manner indicated, rinderpest will soon be a thing of the past in South Africa.

CEYLON FISH.

Dr. Watt, in his Dictionary of Economic Products, gives an exhaustive list of Indian fishes of economic value, among which occur the following which are well-known and commonly eaten in Ceylon:—

Cybium commersonii—Seer or Seir fish. The species of this genus are said to be amongst the most delicate of all marine fishes when of the proper size; if under a foot in length they are said to be dry, from $1\frac{1}{2}$ to $2\frac{1}{2}$ feet they are most excellent, while above this they become coarse. Other species of the same genus and also known as "Seer" are *C. guttatum* and *C. lineolatum*.

Cynoglossus lingua—the Sole. Highly esteemed for the table, and considered to be light, nutritious, delicate, and one of the fish that may be safely given to invalids.

Engraulis indicus—White Bait—extensively employed as food, cooked in the same way as white bait.

Eetroplus maculatus—the Sinhalese "Rallia," and *E. swathensis*—"Corallia."

Harporodon nehercus—the Bombay Duck. Highly esteemed as food whether fresh or salted, and in the latter form extensively employed as a relish with curries and known as "Bombay Duck."

Lates calcarifer—the "cock-up," or "nair fish" (Koduwa). Good eating when obtained from the vicinity of large rivers; salts well and prepared as "tamarind fish."

Anabas scandens—the climbing fish (Kaviya). This fish is most remarkable for its powers of living in the air and can travel a long distance on land. It is esteemed as a nourishing food.

Saccobranchus fossilis—the scorpion fish, a freshwater fish of Ceylon, attaining one foot or more in length. It is considered very wholesome and invigorating by the natives.

Rynchobdella aculeata—the sand eel (theluja). Found in brackish waters within tidal influence. It is excellent as food though objected to by some owing to its resemblance to a snake but it is less disgusting in appearance than the muræna; by Europeans this is considered the best of the eel-kind.

Rynchobatus anchlostomus—the Mudskate. The skin of this, as of other skates, is valued; also the fins and livers.

Pristis cuspidatus—the Saw Fish. Attains up to 20 feet. The flesh is highly esteemed, the fins and skins and livers are all valuable (Tamil, vela min).

Ophiocephalus striatus—the walking fish or murel (Lulla). A freshwater fish which with *O. marulius* (another species) affords excellent sport and good food. Very suitable for stocking tanks.

Mugil (various species)—Mullet. Considered excellent eating, but perhaps rather too fat and rich for delicate stomachs. The spawn salted and dried forms a sort of "cavier" called by the Italians "Boborago."

Mastacembelus armatus—the spined or thorn-backed eel. Found in brackish waters. Attains two feet or more and is good eating, especially curried or fried.

Lutjanus argentimaculatus—the red-rock cod, found throughout the seas of India. Attains upwards of two feet in length and is good eating. The other species of this genus though eaten are rather insipid. They are extensively salted and dried in some localities, and are also known as Singara and Senan Karawa.

Sillago sihama—whiting; supposed to have special milk-forming properties like shark's flesh

By far the most thorough and satisfactory method of inducing the desirable spongy condition of the soil, is the simple yet expensive and laborious operation of trenching. Much has been done by the implement-maker to effectively break up raw earth and let vital air into it; but for the most part these mechanical appliances, however successfully they deal with such tilth as may suit cereals or even root crops, do not go deep enough for the best orchard preparation, except at an expense for steam-gear which brings their work pretty close to the cost of the much more effective hand labour of trenching. The great thing to be wished for in this regard is that the fruit-grower shall deal as handsomely by his orchard as he has, through long custom and prescription, habitually dealt by his vineyard. The depth to which the trenching should penetrate depends greatly upon the nature of the soil. It must be remembered that if in clay-land it penetrates only two feet, the drainage of the rain-water and much of the irrigation-water in spring and summer will creep along that two-feet level. The deeper therefore, under such circumstances, the cultivator pushes such trenching, by so much does he lower the water-table, and gives his trees immunity against water-logging of their roots. Should the soil be sandy and naturally open, rapidly relieving itself of surplus water by percolation downwards as well as along its natural slope, the necessity for deep trenching is not so absolute, and limits itself more particularly to the aëration of the soil.

Under any circumstances a sufficient number of drains should be taken down the main slope in every part of their course, and should descend into the sub-soil a little lower than the depth to which the trenching has been regulated.

An excellent system of drainage consists of what are known as French drains. These drains are formed of a V-shaped trench cut down into the subsoil straight along the main slope of the land, care being taken to leave the bottom of the trench unbroken and in an exact plane, since if its level varies in the least the water will not get a free outflow and pools will form in its course so that much of the value of the drain will be lost.

The cutting of really good drains without flaws is a skilled operation. Drains that have been patched up by repairs, that is by ramming materials over parts that have been cut too deep will always be weak soft spots where the water will tend to hang. It is therefore best to give work of this nature to skilled workmen, seeing that the work will be better and more economical, because more rapidly executed. The bottom of the trench in these drains will as indicated above be narrower in width than the top. After cutting the trenches, it is usual to fill the channel with rounded river pebbles or similar rubble to a depth of 9 in. or a little more. Angular fragments should if possible be avoided as they do not give such large interstices and are more apt to cause clogging and stoppage. Upon the top of the pebble bed it is customary to put a layer of brushwood well battened down. The object of compressing the brushwood is to work the layer together and prevent filling from soil dropping down to the pebble-bed. When cultivators recognise that good drains are so much capital which constitutes a profitable outlay, they will use something more lasting in the place of

FRUIT CULTURE.

(Continued.)

No great reflection will be needed to show that the proper selection of a locality for an orchard may very materially diminish the amount of labour and expense required to produce the mechanical condition so much to be desired. Unless absolutely confined to a definite acreage without a chance of skilled selection, no person would attempt to establish an orchard on a compact clay, or in a place where the level of the ground relatively to other properties rendered it the recipient of surplus water from above. It is essential even when a man chooses his ground and receives no surplus water from his neighbours, that there be the freest possible outlet for his own drainage, whether of rain or irrigation water. The most favoured localities for orchard should be on a gentle slope to ensure the best conditions as regards water, so as to fulfil the proverbial saying "soon on, soon off," which concentrates in itself a good deal of gardening wisdom. The water-level should never reach the average depth of the roots.

brushwood, which must ultimately, after a few seasons, moulder away and help to fill the openings in the pebble layer. The best plan would be to procure old galvanised sheeting and cut it into strips about a foot and make them serve as drain roofing; a coat of coal tar or gas tar on both sides will double the length of service of the iron sheeting. This plan will treble or quadruple the term of usefulness of an ordinary French drain.

(To be continued.)

GENERAL ITEMS.

Sir W. Wedderburn in his series of papers on the Agricultural Problem in India thus refers to the subject of agricultural banks:—Now the recognised method of supplying working capital to peasant proprietors is by the establishment of agricultural banks. In Germany alone there are some 2,000 such banks doing a business amounting to something like 150 millions sterling with immense benefit to the rural population. Every other country in Europe has followed the example of Germany: the Autocrat of All the Russias started such banks with liberal support; and even the unspeakable Turk has made some movements in the same direction. In India alone nothing has been done. The Autocrat of the India Office would neither move himself, nor allow others to move.

Maize growers will be interested to learn that at length a discovery has been made that may turn out of incalculable value to growers of the crop. A well-known ship-builder in Philadelphia (Mr. Cramp) has announced that a chemist under his patronage has discovered that, through a certain process, the stalks of maize will furnish material for a large variety of articles, notably paper, matting, smokeless powder, sugar, etc. Hitherto maize stalks have been of little or no value, except, of course, when a crop has been grown for green food. By this discovery, however, it is alleged that the stalks will be worth at least £1 per acre. In fact, the enormous area of land in America devoted to maize will make this by-product—the stalks—more valuable than cotton seed, at one time such a nuisance, but now of immense value every year.

A certain person calling himself Kwassie Musean writes to the *Locomotief* from Banjoemas stating that he has discovered a leaf of a certain tree, which is a native to all part of Java, as a remedy against

whiteants. By placing one or more of the leaves in the haunts of the whiteants one could get rid of them altogether. He is prepared to make known the remedy on payment of a sum of 3,000f.

Veterinary work would seem to be making rapid progress in Bengal. We read in the report for the year 1896-97 that at the Hospital in Calcutta "479 animals were treated as in-patients and 248 as out-patients, or 729 in all. The total shows a decrease of 46 cases, but the number of in-patients shows an increase of 42—a fact which no doubt indicates that confidence in the institution is growing among owners. The Superintendent proposes to modify the scale of fees with a view to securing a large number of patients. An ambulance has recently been provided to convey sick animals to the hospital." There are also dispensaries at other centres, supported by local subscriptions with a grant from the District Board or by the Municipality.

Some-time ago we referred to the variation of the Indian maund. A correspondent to the *Indian Agriculturist* now complaining of the anomalies of the system of Weights and Measures refers specially to the seer, and says: "Within a circuit of twenty miles from the place from which I am writing (Barharwar) there are no fewer than four standards for the seer—112, 92, 80 and 75 tolas respectively. The calculation of these is most confusing, and at this time of famine we can never be quite sure as to what the real price of rice is. A letter came to me saying that rice was selling at 6 seers for the rupee. I found on enquiry that it was the large seer of 112 tolas which would mean 8½ usual seers." The correspondent suggests that the Diamond Jubilee year be remembered by the introduction of the metric system throughout Her Majesty's Dominions.

The outer coat of the seed of the *Cannas* is as is well-known very hard, and without help the germ is seldom able to break through. It requires heat and moisture, and the best way, says a well-known grower, is to soak the seed in very hot water for about twelve hours before planting. Let the seed bed be exposed as much as possible to sun and water frequently. Even then only few seed germinate, and that too most irregularly. Some authorities recommend filing through the outer coat, others the use of boiling water.

WILLIAM WALKER.

* The TROPICAL AGRICULTURIST *

◇ MONTHLY. ◇

Vol. XVII.]

COLOMBO, NOVEMBER 1ST, 1897.

[No. 5.

“PIONEERS OF THE PLANTING ENTERPRISE IN CEYLON.”

(Second Series.)

WILLIAM WALKER:

MERCHANT AND ENGINEER:—1854—1891.

[The result of our application to Mr. Edmund Walker for such particulars of his father's life as would enable us to include a notice of his career among the “Pioneers of Ceylon,” was that our good friend set to work and prepared in booklet form a most interesting though brief biography intended for private circulation, but allowing preference of selection for the *Tropical Agriculturist*. The little book, we must add, is got up in the first style of the printer's art, and besides the same portrait of Mr. Walker as we give, it includes an exquisite reproduction of “Doune Castle from the Bridge of Teith,” near which Mr. Wm. Walker's youthful days were spent. The booklet also includes quite a selection of the verses by “Brown Palmer” and “Sandy M'Alpine,” under which sobriquets the late Mr. W. Walker wrote freely in the home press and to the *Ceylon*

Observer. The biographical notice is introduced as follows:—

“In the exceedingly interesting volume already published under the title of *Pioneers of the Planting Enterprise of Ceylon*, the proprietors of the *Ceylon Observer* have been good enough to include a sketch of the life of the late John Walker, and it seems fitting that this should be followed by a brief outline of the life of his brother William, who for so many years was associated with him in developing the business known all over the colony as “Walker's.” The two brothers, who for so long were united in business, were not long separated, John being taken ‘Home in October 1889 and William in June 1891.”

We now give our summarized selection from Mr. E. Walker's fuller notice, only regretting that exigencies of space prevent our appropriating more of the very interesting record of good work appertaining to one of the most esteemed of Scottish worthies connected with the annals of Ceylon as a British Colony:—ED. T.A.]

WILLIAM WALKER was born in Doune, Perthshire, Scotland, in 1824, and attended the village school there. At an early age—for his parents were not in a position to keep him long at school—he entered the office of the

Deanston Works, where he worked for a number of years, and was fortunate in having as his master the late Mr. James Smith, who did so much for the people of Doune, and whose name is still remembered affectionately by a few of the older people. During this time, being eagerly determined, like so many Scottish lads, to push his way in the world, he continued his education by attend.

ing evening classes and neglecting no opportunity for improving himself. He was fortunate in having the help of his schoolmaster, who was interested in the lad, evidently recognising that he was "a lad o' pairts" and might do the "dominie" credit yet. This insatiable thirst after knowledge followed him all through life, and we find him at fifty years of age learning French, and at sixty taking lessons on the violoncello, which he played with great taste and feeling, for his soul was full of music.

It was only natural that one of his ambitious spirit should soon begin to look beyond the horizon of his country village, for he was aye "biggin' castles in the air," and Doune did not seem to offer sufficient scope for his boundless energy. So in due time he consulted Mr. James Smith, and that good man gave him every encouragement, with the result that he went up to Glasgow to mix with the busy throng there. By-and-bye he got an appointment in the Calico Printing Mills, Thornliebank, near Glasgow, under the late Mr. Walter Crum. About this time, in the year 1842, the five brothers, Duncan, James, Ebenezer, John and William, all met together in Glasgow; but that meeting was never repeated, and now they are all gone with the exception of Ebenezer, who, after thirty-eight years' faithful service in the great ship-building firm of Randolph Elder & Co. (now The Fairfield Ship-building Co.), Glasgow, retired in 1881, with remarkable expressions of goodwill from the heads of the Company, and is still hale and hearty, though now in his eighty-fourth year.

In June, 1846, when only twenty-two years of age, William married Ellen Fortay, daughter of James Fortay, of Inverness, who for many years commanded the revenue cutter *Atalanta*, and was engaged in looking after smugglers on the west coast of Scotland. It was an early age at which to marry, and many people would say a very foolish thing to do for a young man who had yet to make his way in the world! But William had confidence in himself, and felt that, given a chance, he would get on all right. Besides the wisdom or otherwise of such a step depends very largely on the choice the young man makes! The reverence and affection in which the widow is held to-day by all who know her, and most by those who know her best, testify to the fact that the choice in this case was a wise one.

The next important step in the life of William Walker was when he entered the firm of Messrs. Wilson, James & Kay, now Messrs. James Finlay & Co., of Glasgow, and Messrs. Finlay, Muir & Co., of Calcutta, Bombay, and Colombo. It is interesting to note that while in the service of this firm he worked alongside of Mr. John Muir, who afterwards became Lord Provost of Glasgow, and is now Sir John Muir, Bart. Both young men were fortunate in having as their master one of the kindest-hearted of men—Mr. Alex. Kay—who years ago retired from the firm, and who, though now a very old man, still lives in his beautiful country seat at Biggar in Lanarkshire. William Walker was building up his character, on which alone, coupled with hard, conscientious work, he depended for his success. He had no other capital, and no influence to secure advancement; [but then "Character" is the most truly, permanently valuable thing in the world?—ED. T.A.]

The time had now come when William Walker thought he might start on his own account in the cotton-yarn trade, then one of the most flourishing trades in Glasgow, and the one for which his past training had specially fitted him. He received a

fair measure of support, and would no doubt have prospered but for an unfortunate event—an event which was a sore trial to him at the time, though it was just one of those influences which made for the establishment of his character. Through the failure of Messrs. Blank & Co., cotton-yarn manufacturers, with whom William Walker had an account, he met with a great loss, and it became necessary for him to compound with his creditors. With one exception, he received great sympathy from those who suffered through him, and they did not hesitate to show it the day they met in his office. Mr. Alex. Kay was at that meeting, and such was his estimate of the character of his former assistant that he ventured at the meeting to say, "I may not live to see it, but I feel sure of this, that if Mr. Walker is spared he will pay up this debt." And Mr. Kay's confidence was not misplaced, for from that date it became the life-work of William Walker to pay off everything due to his creditors. It was a long effort, requiring great patience and much self-denial, for the claims of a large family were pressing on him; but his wife nobly seconded him in his efforts, and was able, twenty-five years afterwards, to rejoice with him when in 1875 he made the last payment. By that year every creditor had been paid, with interest at five per cent. per annum in addition; and thus was preserved unscathed the only capital with which he started—his good name. The creditors were anxious that public notice should be taken of an experience not too common in commercial life, and proposed to entertain Mr. Walker at a dinner, and have the proceedings published; but he begged them to take no such steps, as any public notice of what he regarded as merely the discharge of his duty would be exceedingly objectionable to him.

In 1854 William became the buying agent at home for his brother John, and established himself in Glasgow under the style of Walker Brothers. Later on, in 1862, he became partner with his brother in the Ceylon business, then known by the name of John Walker & Co. It was a small business in those days, but with the boom in coffee it was destined in due time to play a not unimportant part in connection with the history of Ceylon's planting industry. The following extract from a letter written by John from Kandy, Ceylon, to his brother William in Glasgow, gives a graphic account of the business in its early days. The letter must have been written somewhere about 1856:—

"The buildings may be valued roughly at £400 sterling. The motive power for driving lathes, bellows, etc., is the Malabar cooly, as we have not water enough for the blacksmiths' troughs, and fuel is expensive! Our customers are among three hundred planters scattered over the Central Province. As a class I would call them good customers, but some are very long in paying. Our workmen begin work at 6 a.m. and stop from 10.30 to 12 noon, when they resume work until 5 p.m. I am usually in the place from 6 a.m. until 5 p.m., less three-quarters of an hour for breakfast, and same for dinner. We have generally employed twelve to sixteen carpenters, four blacksmiths, five or six fitters, three or four turners, four or five boys, and ten to twelve coolies. There is quite enough of opposition to us to ensure the planters fair terms. We have in Kandy another similar establishment, carrying on all our branches of business."

From the above it will be seen that the firm employed at that period from thirty-eight to forty-seven native workmen; and to-day the number is about twelve hundred, while other large concerns of a similar character have also been established in the colony. No wonder the brothers were a little proud of the business which they had seen grow up and develop in this remarkable fashion!

In 1864 William made his first visit to Ceylon, to take charge of the old business at Bogambra during the absence of his brother John on a trip home. While in Kandy his time was very fully occupied with business arrangements, and from a pencil diary which is in my possession I find that even then he recognised that Colombo must become the capital and centre of Ceylon's business, and proposed that the entire business should be removed to Colombo. But the time for this change had not yet come.

Estate after estate in the Central Province was being cleared and planted with coffee—preparing for the good time coming. "Mr. Turner has just sold his Hantanne crop for fifty-four shillings per hundredweight—a splendid price." So wrote John to his brother William about 1857; but in later years coffee-planters received more than double that price for their produce. "The highest level of prosperity was reached in 1868, 1869, and 1870, in each of which years the total exports of coffee exceeded a million hundred-weights, of a value in European markets of not less than four millions sterling."* This "boom" in coffee kept all industries busy, and it became necessary to extend, not in Colombo, but throughout the leading planting districts. Branch establishments were started in Dimbula, Dikoya, Badulla, and Haldummulla. The life in these young districts was at first a rough one, and the assistant who was sent to take charge of the Dikoya branch, and who is now a director in the company, sometimes tells how his room above the store was furnished. His table consisted of a packing case, and his chair was a keg of blasting powder!

With this rapid extension of the Ceylon business, including heavy expenditure for stocks for the new branches, arose the necessity for a great deal more capital than the two brothers possessed; but the good name William had established in Glasgow, coupled with that of his brother John in Ceylon, enabled him to find all that was necessary. Satisfactory financial arrangements were made with Messrs. Blank & Co., and everything went on well until 1874, when William's faith was again destined to be pretty severely tested. For the sake of those young men who may read this record, the story ought not to be omitted; and it is due to Mr. Kay, who proved so kind a friend to his old assistant during all these years and to the end of his life, to mention it.

One day in 1874, just at the very time when Walker Brothers' account with Messrs. Blank & Co. stood highest, in consequence of the large advances required in connection with this establishment of the up-country branches, the senior partner of the latter firm called. He then informed Mr. Walker that, being well advanced in years and anxious to curtail all outstanding, so as to simplify his financial arrangements as much as possible, he would like Walker Brothers not to draw any fresh drafts on his firm, and hoped they would be able to run off the debt by taking up existing bills as they

fell due. Mr. Walker, recognizing how much he owed to these financial friends, could only reply that to the best of his ability he would endeavour to carry out Mr. Blank's wishes. Though not knowing at the time where help was to come from, yet, being a man of strong, simple and devout faith, he felt that he would not be forsaken in this crisis.

When in his office one day at this juncture, Mr. Kay called, just to have a chat, and in a kindly way to inquire how his old friend Mr. Walker was getting on, though he knew nothing at the time of his trouble. Nor was the subject mentioned until, in course of conversation, Mr. Kay said, "I have been thinking I would like to help you, Mr. Walker, if there is anything I can do that would be a personal benefit to you. Now, would it assist you to have the command of a little more capital than you at present possess?" Mr. Walker then, for the first time, told the position in which his firm was placed. As the result of that interview Mr. Kay—after satisfying himself that the business was perfectly sound, full of promise, and only in need of more capital, and having perfect confidence in Mr. Walker—went to a leading Scotch bank and opened a credit in favour of Walker Brothers for all that was required, at an expenditure of a penny postage stamp! Needless to say that the prosperity of the Ceylon business has long since enabled the proprietors to dispense with that credit, and placed both houses beyond the need of any such help.

As already stated, Mr. Walker, as far back as 1864, contemplated removal to Colombo; but so rapidly did the business increase, both in Kandy and at the up-country branches, that further extension schemes had to be abandoned; and though in 1875 premises in Colombo were leased, and rent paid for three years, they were never occupied. By 1880, however, the collapse of King Coffee was placed beyond doubt, and it became necessary for the firm to turn their attention to other channels. At this time the grand breakwater for sheltering the Colombo harbour from the south-west monsoon was nearing completion, and circumstances all seemed to point at last to removal there. Accordingly, in 1881 the premises formerly occupied by the late Mr. Home, and known as "The Corner," were leased by the firm, and no time was lost in laying down new plant and getting the new workshops and stores ready. It required a great deal of faith to go on with this work, as the prospects of the colony at the time were about as black as could be. Planters of the highest standing up-country were being ruined, and the mercantile houses were coming down one after another, until the crisis culminated in August 1884 by the stoppage of the old Oriental Bank Corporation. It is, perhaps, not to be wondered at that amidst all this gloom, a Colombo merchant, when he saw in 1883 that, in addition to the workshops, a new foundry—the first in the colony—was being built, should exclaim, "Has Walker gone mad?" But every one was not of that opinion, for in July 1883 the *Ceylon Observer* wrote:—"It is well that when the time came for an era of new life to the port and trade of Colombo, the right men were ready to meet the crisis and provide its requirements. The names of Kyle, Grininton, and Walker & Co. will be honorably associated with the New Colombo which is rising as the result of the partial completion of the Breakwater, and the resort to Colombo of many lines of mail, passenger and cargo steamers."

* From "Ceylon in 1893," by John Ferguson.

Meanwhile, Mr. John Walker, who after more than thirty years of hard work in Ceylon, did not care to undertake the burden of further extensions, and had settled with his family in Stirling, decided to retire from the firm he founded, and an arrangement was come to whereby he agreed to take over the up-country places of business and carry them on under the style of Walker & Greig, leaving the Kandy and Colombo establishments to John Walker & Co. William Walker now became senior partner in the Ceylon business, as well as in that of Walker Brothers, who, after the opening of the Suez Canal, found it necessary to remove from Glasgow to London, and who, in addition to Ceylon, have now very large interests in South Africa. Although his home was in Glasgow, Mr. Walker frequently visited Ceylon, as he had no sympathy with "absentee landlordism," and desired to keep in touch with all, from his junior partners down to the office peons, who were engaged in the Company's service. Sometimes his family felt that he was not sufficiently strong for these visits to Colombo, and when the last trip was made, in 1889, I can remember Captain Bayley, who was struck with his appearance, urging him not to return to Ceylon, and concluding his remark with, "Remember the fable of the pitcher that went once too often to the well." But Mr. Walker loved Ceylon, and had a warm heart for the natives, to many of whom he was indeed a real friend.

Throughout his life William Walker was deeply interested in all schemes for the uplifting of those whom we describe as the "working classes." The term is very defective when we remember the number of masters, professional men, merchants, etc., etc., who work as hard as, if not harder than, the majority of our workmen. Still, it has its special meaning, and in that special sense I use it. He always deplored the struggles between masters and men, which have wrought so much mischief to trade and roused so much ill-feeling, destroying utterly the old kindly and personal relationship which used in many cases to exist between both. He had little faith in Trades Unions, which he regarded as in large measure involving the transfer of the men from one tyranny to another; and when, as so often is the case, they deliberately go out of their way to sow discord between master and men, he considered their work diabolical. It was not in Trades Unions he saw hope for a better state of things, but in co-operation and profit-sharing, which in the later years of his life he advocated, in season and out of season. I cannot give a better exposition of Mr. Walker's views on this exceedingly interesting question than by quoting from a pamphlet called "Christianised Commerce," which he wrote and published in 1888, as follows:—

"I am for freedom, not socialism. I am for freedom in our dealings with other nations, in our manufactures, in our merchandising, in our contracts between employer and employed. Freedom for every man to do his best for his own truest interest, and for the good of the community; but freedom tempered and controlled by the teaching and example of Christ. I see no other solution of the pressing social troubles and difficulties of our day."

So earnestly did he believe in this as the right principle that he laid aside a portion of his own share in the business, the income from which was to be divided among those who con-

tributed by their work to earn the profit. When on one of his visits to Ceylon in 1886 he was invited to meet some three hundred of the Company's employes, who presented him with a beautiful address, accompanied with a handsome desk made out of Ceylon native woods. In acknowledging the gift he said:—

"I desire as much to be your friend as your master. I think that the firm with which I have been connected so long as its head has done good work for Ceylon. We have brought works to the Island that were never brought before. We have also paid large amounts in wages every month to the Sinhalese and Tamil workmen. But we think we can go on a step further and do better. The first thing I will try to do for you will be to afford you medical aid in time of sickness. I wish also that some provision be made for any one who meets with any accident, or in cases of any protracted illness. The next thing I wish is that something be provided for our men when old age comes on and you are not able to work. If this is carried out, no old and steady worker in the Company's service will ever have to apply to the Friend-in-Need Society." The scheme thus formulated was carried out, to the great benefit of the workmen.

In the year 1890 Mr. Walker was persuaded to agree to the conversion of the Ceylon business into a Limited Company. For some time he had great misgivings about this step, as he feared the elimination of the personal element and dreaded the possibility of the business becoming a mere instrument for grinding out dividends for shareholders who had no interest in the concern beyond their shares. He was afraid that the government of the business by a "Board of Directors" would tend to blight personal responsibility, and was inclined to regard a "Board" in much the same way as Sydney Smith did corporations when he said "they had neither a body to be kicked nor a soul to be damned!" And so it was only under certain conditions he would agree to the change in the constitution of the business; and one of these conditions was that certain shares, the most of which he himself provided, should be set aside, and the income from the said shares be devoted to the formation of a "Provident Fund." This Provident Fund meets all expenses for the workmen when laid aside through ill-health; funds them in medical advice and in medicines; and finally, when the men are too old to work, or permanently disabled, secures to them a small pension. From this fund thousands of rupees are thus distributed every year among the men, in addition to their wages; and the members of the European staff also benefit by it.

In the preceding pages I have endeavoured to give some of the leading points in the business career of William Walker's life; but it is only one aspect of the life, and probably he himself would say it was the least important, except so far as it was a "means to an end." For mere worldly prosperity he had supreme contempt; but the joy of being in a position to "help lame dogs over stiles" was genuine, and many less fortunate ones have had cause to bless his name. He cared little for public subscription-lists, where people's names and contributions are advertised to the world. His belief was that if each member of the community, in a position to do so, were simply to attend to the cases that come across his or her path in life, then there would be a tremendous reduction in the sum-total of human misery.

From his youth he was an earnest total abstainer from all intoxicating drink. He joined the Scottish Temperance League shortly after its formation. His name appears in the first annual 'Register' published by the League in 1849, where it has stood continuously year after year ever since. From 1853 to 1856 he was a member of the Executive, and was for many years, and up to his lamented decease, an honorary director of the Institution. He was a most liberal subscriber to the funds of the League, and in many ways sought to extend its influence.

Throughout his life Mr. Walker was always busy with his pen. When in the company of those who thoroughly understood him, and with whom he felt perfectly at home, he was the very life of the gathering, full of good stories, and able to sing with exquisite pathos our chief Scotch ballads. This reference to his singing leads naturally to a quotation from the most beautiful of all the printed notices published at the time of his death. It appeared in the *Ceylon Observer* of June 15th, 1891, and is greatly valued by the family. Between Mr. Walker and the proprietors of the *Observer*—the late Mr. A. M. Ferguson, C.M.G., together with his able partner and successor, Mr. John Ferguson—there existed a sincere and warm friendship. I quote from the article referred to as follows:—"Mr. Walker's love of music and song was intense, and those who heard his illustrated lecture in Colombo on Scottish Poetry, Music, and Song, will long cherish the memory of a great intellectual treat. His own performances as a singer were exquisite. Who that heard can ever forget his rendering of Lady Nairn's pathetic ballad, 'I'm wearin' awa', Jean,' and George Macdonald's Scotch version of the grand parable of the good Samaritan, 'Wha's nae neighbor?' Who that heard and saw can ever forget the expression of voice and features, and the appropriate action of the truly artistic singer?"

In his youthful days William Walker must have worshipped in the parish church before the Disruption in 1843; and there is more than one reference, in articles written by him, to the Bridge of Teith Church, near Doune. But at an early period in his life he joined the Baptist Church, and for many years attended the Blackfriars Street Church in Glasgow, where he greatly appreciated the thoughtful and devout ministry of Dr. R. Glover, then a young man, but now (of Bristol) one of the leaders in the Baptist community. During the later years of his life he attended the Hillhead Baptist Church, where the Rev. F. R. Roberts still carries on a most successful ministry. Though a Baptist by conviction, yet in religion, as in all other departments of life, he claimed for himself, as he allowed to all others, the utmost freedom; and so we find him equally at home among Non-conformists of different denominations and Evangelical Churehmen.* Not only was Mr.

* One of many interesting experiences in Mr. Walker's life was that which brought him through temperance work, in contact with an earnest but extremely High ritualistic clergyman off City Road, London, who begged of him to come and give an address to his people. When the occasion arrived, and Mr. Walker watched the procession passing to the hall and all the symbols and forms accompanying the opening service, he felt far from comfortable and honestly stated how widely apart belief and practice were from all this, and then went on with his address in which he introduced one or two pathetic Scottish ballads. After

Walker actively engaged in Church work at home, but he took a great interest in missionary work abroad. He never visited Ceylon without devoting a great deal of time to this work, going right round the Island on one occasion, in order that he might see what was being done at the different mission stations along the coast. In 1886 he made a special trip to Bombay and the north of India to get some knowledge of the missionary work carried on there, especially in connection with mission schools and colleges. How best to work our missions and utilise the consecrated energies of our missionaries must always give anxious thought to all who are truly interested in the work, but anything like dogmatic assertion on these points must be left as the "prerogative of the passing tourist," to use the delightfully sarcastic phrase of Dr. Copleston, the devoted and able Bishop of Colombo. Mr. Walker wrote a number of very interesting letters to the *Ceylon Observer*, giving an account of his trip to India, and we may contrast his calm and judicial remarks with the extravagant utterances too often made by the "passing tourist." Thoughtful men cannot but realise that our missions in India and China, where the people are steeped in elaborate religious systems older than our own, present many a "great and perplexing problem"; but Mr. Walker felt very strongly that it was most unjust to abuse the missionary. Let those who sneer at the results of their work and the apparently slow progress that is being made, devise a more excellent way, and prove their earnestness by paying for the experiment.

In politics Mr. Walker was a staunch Liberal until April 8th, 1886, when Mr. Gladstone introduced his Home Rule Bill and broke up the grand old Liberal party that included such men as Bright, Chamberlain, Lord Harrington, Foster, Goschen, and many others. Bright and Foster are no longer with us, but the others are among the men who are today making this country's history, and many old Liberals feel it is a pity they had to go to the other side to do it. For the whole of his life, Mr. Walker, of the House like many others, almost worshipped Gladstone and when the crisis of 1886 arose, he felt as if he had lost a personal friend. He had taken his share in fighting for the different Liberal measures of a whole generation, but I do not think he even voted after 1886.

When he did take a holiday his great pastime was burn-fishing, of which he was enthusiastically fond; and then he was like a boy just let loose from school. His whole soul responded to the beauties of nature, and he seemed to find and see God everywhere.

Such is a brief and all too imperfect record of the career of one who, beginning life in a Scotch village, sought to live to some purpose, and with good effect, to make the most of what ever talents he possessed. He humbly but earnestly believed that for those who seek to do what is right "God shapes the fitness of us all, and gives to every man his meaning." Life for him was full of meaning, and the meaning of his life to those who come after him becomes richer and more beautiful as the years pass by. It is something to make the little corner of the world in which a man lives the better for his being in it; and that is what Mr. Walker managed to do.

all was over and the audience gone, the ritualistic clergyman came and shook hands beaming all over and exclaimed out of a full heart to Mr. Walker:—"I do love you!" Wide as the poles asunder, denominationally and doctrinally, and yet brothers!—Ed. T.A.

A few months after his death the clerks and native employes presented the Company with a very good and handsome oil painting of their late master to be hung in the office. After the presentation the manager, astonished at the costly character of the work, expressed to the chief clerk, who headed the movement, his fear that the cost must have been more than the men could well afford from their pay. It was then explained to him that at first it was proposed to levy a percentage from the pay of each of the workmen and staff. "But we thought," said the clerk, "that Mr. Walker would not like that, as it would seem like forcing contributions. So last pay day we placed a box at the gate for the men to put in it whatever they felt inclined to give; and we got more than was required." Nothing could have been more in harmony with the spirit of him who was so long their master, and it shows that even the native clerks had caught something of the spirit of his teaching.

There is a little thatched cottage occupied by a small farmer or crofter in the West Highlands of Scotland. A merchant from Glasgow one summer, when on a holiday, visited the cottage, and on looking round the parlour was surprised to see on the mantelpiece a photograph of Mr. Walker.

"Do you know Mr. Walker?" asked the merchant.

"O yess," replied the farmer's wife, with the sweet Highland accent; "he used to bring his family here for the holidays when the children were young. He *iss* a good man."

"Yes," said the merchant, as he looked again at the photograph, "there is no better man walks he streets of Glasgow."

"When I die, put near me something that has loved the light, and had the sky above it always." These words express exactly the feeling of Mr. Walker, for though death had no terror for him he often said that he hoped he would never be buried in a city cemetery—like the Glasgow Necropolis—where flowers cannot grow and Heaven's light is for the most part of the year made dim with the dark canopy of smoke overhead. And so, on June 16th, 1891, he was laid to rest in the little country grave-yard belonging to the parish church at Cathcart; "until the day break, and the shadows flee away."

So passed away in his 67th year, one of the truest and best men who ever came to this Colony of Ceylon: his "pioneering" in one direction alone led to the expansion of industries with a staff under 50 to one of over 1,200 workmen, and he lived to see the usefulness of his Colombo and Kandy houses not only recognised all over Ceylon, but in India, the Straits Settlements, Java and Borneo as well as in far-distant Brazil and in the West Indies; while not a few ocean-going steamers have benefitted by the prescience which established the Colombo Iron Works. With these Works, the name of William Walker will ever be indissolubly associated, while all who knew him will acknowledge with us that a more single-hearted and altruistic Christian never lived:

"Only the actions of the just
Smell sweet and blossom in the dust."

A HOME-MADE ARROWROOT MILL.

We were lately asked by a farmer in the Blackall Range how to make an arrowroot-grinding machine. He had arrowroot growing on his farm, and wished to make enough starch for domestic use. The only method he knew of was to grind down the hulbs on a large tin grater, but the results did not compensate for the labour. As we were once in exactly the same predicament, we cannot do better than describe the primitive machine which we invented, and which proved eminently successful. Being far distant from any place where a machine could have been constructed, not to mention the detail of a scarcity of cash, we constructed the machine as follows:—First, a log about 2 feet in diameter and 8 feet long was hollowed out by axe and adze into a trough. At the head of this trough was fixed a framework much like the wooden stand of a grindstone. A large wheel was then cut from a sound log. This wheel was about 3 feet in diameter and 1 foot wide. Tin plates, turned into graters (which required frequent renewal) by punching holes in them with a nail,

were next nailed on to the edge of the wheel, to which a wooden axle was fitted. The wheel, when placed in position, turned in the water with which the trough was filled. Above it was a wooden hopper, through which the hulbs dropped on to the wheel. This was turned by a man with ease, and the grated hulbs went into the water in the shape of pulp and starch. The latter gradually settled at the bottom, and the pulp was removed with a narrow-tined fork and also by hand. After a short interval to allow the starch to settle down firmly, pegs were withdrawn from the lower end of the trough, and the water drawn off. The arrowroot was then dug out of the bottom of the trough and passed through calico stretched over a tub. By stirring it round with the hand on the calico, and at the same time pouring water on it, the whole of the starch passed through into the tub, leaving the gross impurities behind. This operation was performed three or even four times, until the arrowroot was perfectly white and quite free from any foreign substance. After the last washing, it was placed on shallow trays and dried. With the machine described, we not only made sufficient arrowroot for our own use, but we sent a quantity home to our friends, and sold the balance in Brisbane at 1s. per lb. This was in the year 1863. Such a machine, however, would scarcely enable a grower to-day to make a profit out of arrowroot.—*Queensland Agricultural Journal.*

THE CULTIVATION OF CACAO IN MEXICO.

(From a Special British Consular Report.)

The tree that produces the "food of the gods" (chocolate), "*Theobroma cacao*" of Linnæus, "cacari," or "cacava quahuil" of the ancient Mexicans, and "cacao" of the Spaniards, is a native of Mexico.

Long before the conquest, the Aztecs and other ancient Mexican tribes used the fruit as one of their alimentary beverages. They prepared a drink called chocolate by mixing the seeds after having crushed them on the metatl, together with a fine corn meal, vanilla ("*tilixochitl*"), and a species of spice called "*mexaxochitl*," and those that drank it were a picture of health, preserving handsome and vivid features even to old age. All nations subjugated under the Aztec eagle had to bring, among other valuables, a certain

number of bags of cacao to the place in the great Tenochtitla as an annual tribute to the Emperor. It was so highly prized amongst the ancient natives that in trade it was utilised as currency among the lower classes.

The varieties cultivated were, namely:—The "quauhcahuatl," "mecacahuatl," "zochicucahuatl," and "tlacacahuatl." The bean of the last one was very small, analogous to the kind found at present at Soconusco, Chiapas. The fruit produced in Zoconochco, in the provinces of Tabasco and Chiapas was considered as the best.

The followers of Hernan Cortez endeavoured in vain to maintain the plantations then existing, but it is a well known fact that on the conquest of this country by the Spaniards agriculture and the industries then known retrograded to such an extent that the cultivation of the cacao as well as that of the cotton plant suffered so severely that both plants were reduced almost to a wild state. The conquered Mexicans were compelled to work in the mines and serve in slavery, and were thereby obliged to neglect their plantations. And as the conquerors were not versed in the culture the industry was nearly abandoned, and did not take a new life until some Spaniards started one or two large plantations in Choutalpa, Tabasco, a few years before Mexico threw off the Spanish yoke. Other plantations were established in different sections of Tabasco and Chiapas.

Chocolate, the product of the fruit, was first introduced into Europe (Spain) by the Spaniards from Mexico. Portugal followed in the use of it; France and England did not appreciate its full qualities until the latter part of the seventeenth century. After the year 1778 it came into vogue in all the cities in Europe. Its alimentary virtues became more generally known, and Doret, a Frenchman, invented a hydraulic machine to manufacture it on a large scale. Since then all civilised nations have consumed this rich American product of Mexican origin, which, up to date, is not produced in sufficient quantities to meet the world's consumption.

This tree is found growing wild and in cultivation in the States of Colima, Michoacan, Guerrero, Oaxaca (districts of Jamiltepec and Tuxtepec), Chiapas (districts of Soconusco, Mezcalapa, Pichucalco, Simojovel, and Palenque), Tabasco, and central and southern Vera Cruz, where the elevation is from 100 to 1,200 feet above sea level, but Chiapas and Tabasco are noted as being its home, the climate and soil there being more particularly adapted to its culture and development than any other portion of the globe.

The production of cacao in the year 1893 was 2,147,730 kilos., valued at \$837,197. In 1870 the States of Tabasco, Colima, Chiapas, Guerrero, Michoacan, Oaxaca, and Vera Cruz had 569,795 trees in cultivation, producing an annual crop of 31,285 quintals, worth to the planters \$782,125.

Cacao is an evergreen tree of medium size, which, if grown in a good soil and left to itself, will reach a height of 20 to 30 feet, and spread out to an extent of 10 feet or more on each side. At the height of a few feet from the ground it sends out three to six lateral branches ("horquetas") without any sign of a leading stem, and it is only when the branches are matured that a leader or leaders ("ramachupona") spring out from the side, and not from the centre of these branches. The leaves are smooth, alternate, lanceolate, pendent, of a deep green colour, 9 to 10 inches long by 3 inches across. The flowers are small, of a pale yellow or very light red colour, and they come off in a bunch from the stem, branches, and the place where a leaf formerly existed. It is rarely that more than one of them develops into fruit, and thus many more flowers are borne on the trees than fruit pods. The cucumber shaped pods are 5 to 9 inches long, and nearly 4 inches in diameter at their widest part, with a thick, almost woody rind. They are pinched in at the top and pointed at the end, the point being curved to one side. The skin is first light green, then of a yellowish red colour, with ten furrows and tuberculated ridges. These

indicate a five-elled fruit, which contains on an average 38 seeds, embedded in its sweetish pulp.

The species most cultivated in Mexico are: Cacao or Theobroma ovalifolia, T. bicolor, and T. angustifolia. There are other kinds known, generally found growing wild, which come under the head of the Guazumæ or guacima, Guazuma polybotrya being the principal species.

Practice and study have shown us that the cacao tree will thrive well in virgin lands recently cleared, but rich in organic matter and minerals, and as it has a long tap root the surface soil needs to be deep and thick with humus. The best soil, however, is that occurring in valleys and undulating lands, along the banks of rivers or streams made by years of alluvial deposits, or by the decomposition of volcanic rocks. A proof of this is shown in the department of Soconusco, Chiapas. It will also grow well in loams and the richer marls, but it will not thrive in stiff, heavy clay.

A warm, moist climate, having a mean temperature between 76° and 77° Fahr., is necessary for the cultivation of cacao if large crops are expected, but when the soil is suitable, the tree will grow and give fair returns in a moderately dry or well drained location. The ordinary cacao plant will not do well in the mountains above 600 metres (1,968 feet), and even at that height it becomes stunted, and is fruitful only for a few years. The best elevation is from 300 to 500 feet, and in sheltered situations near the seashore good crops are to be obtained, but the tree will not thrive if exposed to the direct influence of the sea breeze. Cacao will not bear much exposure, hence sheltered lands and valleys should be selected and on the Gulf side of Chiapas, Tabasco, and Vera Cruz, northern and eastern aspects should be avoided. Still, locations in Colima, Michoacan, Guerrero, and Oaxaca, on the Pacific side, having a south and south western exposure, must not be preferred for the formation of successful plantations.

Cacao plants are obtained from the seed, which germinates readily and quickly. The best looking pods from the April or May crop, which are not over ripe should be picked for the purpose. Those known as hechas are generally preferred by the planters. These are distinguished by their light colour, solid appearance, and the seeds not rattling inside. After selecting the largest seeds from healthy pods, the former are soaked in lukewarm water for 12 or 18 hours, rejecting those assuming a reddish tint and likewise those floating on the water, the rest are left to dry.

A virgin spot close to a spring or stream whose soil is not porous, in the immediate vicinity of the plot to be planted, should be selected for the nursery. For the convenience of handling, more than one nursery should be formed along the plot, 300 feet distant, if a large sized plantation is to be established. The spot is prepared by hoeing the soil, extracting the weeds and roots and pulverising the earth with a rake; then beds are made 5 feet wide by any length, separating each one by a walk 3 feet wide. Small furrows are made, about an inch in depth and about 12 inches apart, and the seeds are sown in them 8 inches one from the other. That part of the seed attached to the stringy centre of the pod is the one to be placed downwards in sowing. The seed is covered with vegetable mould or loose loam mixed with horse manure and over that banana leaves. The bed is sprinkled every day for 12 or 15 days, when seedlings appear. Then the banana leaves are removed, and sheds, made of palm leaves and sticks, so fixed that they can be raised as the seedling grows, should be placed over the nursery as shade and shelter; no weeds or grass are allowed on the beds.

The sprinkling should be continued when necessary, or on rainless days, and the palm leaves are gradually taken off, but not altogether until the plants are ready to transplant. The operation of forming the nursery is done in some places in the months of April and May, and in other localities as late as September.

Either in the month of February or March the planter's attention must be directed to the preparation of the land; in some places, where the rains cease early in the season, that is done in December or January. The forests having been cut down (tumba) the branches must be lopped and strewn (rozada) evenly over the ground before they are burnt (quemada). But when the forest is cleared, shade belts should be left, or afterwards planted in exposed places so as to shelter the cacao trees from the wind.

Of course the felled forest trees must be allowed to remain for a time exposed to the sun, otherwise the smaller branches will not catch fire properly. Where possible it is better not to burn the bush, but to pack it in lines between the young plants or madres, in order that, by its rotting, it may add to the richness of the soil, otherwise the nitrogenous compounds so beneficial to plant life are sent off into the atmosphere by the burning.

Immediately after the burning, which should take place in April, or a month after the land is cleared, corn and beans are sown on the plot. If the land has no natural trees suitable for shade, mother trees (madres) are looked for, such as mataraton, pito, cocoite, chipilcoite, and chontal. The last named, a broad leaved tree, is not good for anything but to give shade and shelter. Cocoite and chipilcoite, small leaved trees, are hard wood and are used by preference for posts for houses. These trees are obtained from forests in the shape of cuttings or young plants, and planted in the beginning of the rainy season and at a distance of from 15 to 18 feet apart on rich flat land, but on poorer soil and on hill sides, from 12 to 16 feet will be the proper distance. Rubber can also be planted as shade, but it requires more scientific work and care. In July and August the corn and beans are harvested, and the plot thoroughly cleaned; the banana suckers can then be planted between every for madres, providing rubber has not been thought of and no preparations made to raise it. In the spring of the following year another crop of corn can be sown between the madres leaving a hill close to the place destined for the cacao seedling which will serve as chichihuas, temporary shade, to the young plant when transplanted. In Chiapas and Tabasco trees called challa and madre serrana are utilised for this purposes. A year after sowing, seedlings are 50 centims. (20 inches) high and ready to be transplanted.

In the beginning of the rains, on a cloudy day, the operation of transplanting is proceeded with. A peon with a machete cuts a square line around the seedling and with a spade (coa) lifts up earth and seedling; this is done in 15 to 20 minutes. Then another peon wraps up the whole mass with a large leaf grown on a plant called hoja blanca, found in those sections. In the meantime the holes are being made, they are dug $8\frac{1}{2}$ feet away from the madres if these are set 17 feet apart, so as to form a square with a mother cacao in the middle. The holes should be 2 feet square and 2 feet deep, that is 8 cubic feet of earth must be taken up, this can be done by a practical man inside of 5 minutes, in soft soil. The earth around the seedling after transplanting must be well pressed with the foot, but at the same time, before finishing that operation, dried leaves are mixed with the soil to be placed on top.

Of course land under cacao cultivation, as under all proper and successful cultivation, should be kept clear of weeds. In the first place the plot should be drained off to ensure quick crops; and then proper tillage will improve the soil and do good to the trees. To accomplish this, 4 weedings (ladeas) are necessary in the first 3 years, 3 in the second 3 years, and 2 in the following years. On steep hill sides cullassing will be sufficient, and on level places hoeing will be required. When the trees are grown so that their branches shade the land, the weeds will not grow very fast, and as a rule they are so loosely rooted that they may be easily pulled up. The cultivation and harvesting of the side crops must be attended

to in due time. The cacao planter should give careful attention to the pruning of the trees and trimming of the madres if he wishes to get a large yield. As the pods are borne on the larger branches, the principle is to develop such branches by judicious pruning and to see that they are not covered up by a mass of foliage and small twigs. A typical cacao tree should have one stem, giving off at a few feet from the ground three to five branches which spread in an open manner and are free from leaves except at the top; thus the leaves shade the open inner portion without interfering with a free circulation of the air. If the young plants throw out more than one main stem, the surplus ones (mamores or chiponas) must be pruned off when the moon is on the wane, and after the lateral branches are formed no upward prolongation of the stem must be allowed to grow. If the tree be left alone these upward growing branches will come off from the stem just below the laterals, in the form of suckers, and to leave them on is to cause the strength to be taken from these fruitful laterals, as well as to allow the trees to run up, perhaps for 30 feet or more thereby causing much trouble in picking the pods. When the suckers are pruned off, fresh ones will grow in a short time, generally in a month, so that the trees will require frequent attention until they are mature, when the tendency to throw out suckers will be stopped. In gathering the pods, the suckers may be taken off at the same time, but the trees should not be pruned in the flowering season.

Unless in the case of sickly plants on poor soil the trees will not require manuring until the crops are taken off, when, as may be imagined, it will be necessary to restore to the soil, in a cheap way, what has been removed in the valuable produce. A good deal will depend on the nature of the soil and the yield of the trees. Should crops which were abundant be found to be falling off, it is an indication that manure is necessary. A compost of yard manure and bone dust in the proportion of 5,000 cart loads of yard manure and 500 lb. of bone dust per hectare of land applied every 3 years is all that is required. The successful harvesting of cacao requires great care and watchfulness, as it is a fruit that has many enemies, the principal being parrots, squirrels, tusas (a species of gopher), tepeiscuintle, another animal of the rodent class, and ants, specially those known under the name of arrieras. But damage by these can be obviated by proper cultivation and care.

Returns from a cacao plantation (motelar) cannot be expected until 5 years from transplanting. At 2 years old the tree, in rich soil, stands 5 or 6 feet high; when 7 or 8 feet high it begins to bear (jugar), but it is not in full bearing (cuaja) until it is between 10 and 12 feet high. The first flowers under favourable conditions will come out at the third year, but, as the tree is not matured then, they should by no means be allowed to produce pods, otherwise the plant will be so weakened by the fruiting that its growth will be greatly checked. The first flowers, therefore, should all be rubbed off.

After the leaves of the flower fall, a bud appears like the common Mexican chile pepper and takes 3 or 4 months to mature. Peons or mozos must be employed daily until the crop is harvested, as birds and squirrels are apt to eat the bud and afterwards the seed. The cacao tree flowers all the year round and the pickings of the fruit are divided into four harvests or seasons. The first, which covers the first three months of the year, is known as *invernada*; the second, lasting through April, May, and June, is the *cosecha* or harvest proper, and is the most abundant of the four; the product of the third, extending over July, August, and September, is known as *cacao loco*; and that of the three last months of the year as *alegron*.

The average yield of dry cacao from each tree of course varies very much. The limits may be said to be from $1\frac{1}{2}$ to 8 lb. per tree.
—*Sugar cane.*

PALLEGAMA GRANT ESTATE.

Sportsmen occasionally find their way to the neighbourhood of Pallegama and we are glad to have independent opinions of the planting in some "Notes"—not from one of a recent party, but gained indirectly:—

"Pallegama has every appearance of being a very fine property in course of time: coconuts and coffee were looking very well indeed, though wild pig and buffaloes do a lot of damage to young supplies. But couldn't the hides and horns of buffaloes be turned into a 'New Product,' and add to the revenue of the estate instead of taking from it? The bungalow is a neat building on the top of a knoll, and has a cart road right up to the door. The whole distance from Matale is 47 miles, and sportsmen often go much farther than that in search of game."

FRUITS AND VEGETABLES:

HINTS FOR MR. WILLIS AND HIS STAFF:

AS ALSO FOR ALL UPCOUNTRY (AND
LOWCOUNTRY) RESIDENTS.

(From a practical Colonist.)

"THE TOTTUM, Sept. 14th:—Don't you think, Mr. Editor, that our energetic Director of Peradeniya Gardens would be conferring a boon on the whole community, if he were to train a staff of coolies that could be hired out as garden workers at so much per month just as gardeners are lent out at home. For instance, if any one wanted a garden laid out or one remodelled, what a convenience it would be to get a cooly who knew how to do it, even by paying a good wage for him!—and an ordinary estate cooly could keep a garden weeded and watered when once it was laid out; and twice a year, say, an experienced gardener from Peradeniya might be had, to put in fresh plants and seeds. The Peradeniya Gardens might do wonders in introducing new fruits that could be grown in our island. I am perfectly certain there would be much less fever in many districts were people to eat more fruit. Even plantains are not to be always had in planting districts, and if oranges, limes, pineapples, papaws, &c., were for sale at the Government Gardens, there would be a great demand for them, and I have often thought a good way of celebrating this year of Jubilee would be for every one in the island to plant 60 fruit trees (of sorts) near bungalows wherever such a thing was practicable. The expense would be trifling and people ought not to be deterred by the feeling that those who planted the trees might not reap the fruit of them. Let us all be disinterested for once in a way: some one will eat the fruit in course of time.

"I fancy the pineapple fibre you wrote about is extracted from the leaves, is it not?—we could grow tons of these. Papaws planted from seed come into bearing in about 10 months at an elevation of 2,400 feet. So papaw juice could also be produced in large quantities."

NOTES ON RUBBER.

The *India Rubber World* of New York is starting a discussion as to the relative values of the rubber of different countries, and certain authorities seem inclined to make out that Para rubber trees are never to succeed in Asia, nor Africa rubber from the Congo ever prove as

good as the rubber from South America. Even the latter proposition is improbable, while we have no faith in the former. Why should not Para rubber prosper well in moist warm Ceylon, just as much as Trinidad cacao has flourished in our upland valleys and Peruvian cinchonas on our hills? We quote from our American contemporary as follows:—

Any hope that rubber may be cultivated successfully in more favourable climates seems to us wholly unfounded. There is no higher authority on this subject than Mr. Mann, late forest conservator in Assam, who wrote recently in *The India Rubber World*: "The acclimatization of American rubber-trees in Asia has not been a success, and, generally speaking, I am now inclined to think that all rubber plants had better be grown in the countries in which they are indigenous." By the way, there is not, and never was, a large plantation of Para rubber-trees in India, although a statement is going the rounds in regard to such a plantation, said to cover 200 square miles. More than this, experiments made in Brazil have demonstrated that, while cultivated trees may flourish, they may not yield rubber on a different soil, or at a higher elevation, than is common to the native rubber forests. Thus it will be seen that the business of planting rubber should not be undertaken without considerable caution.

The cultivation of India-rubber, coffee, and pineapples together is proposed by the Mexican Gulf Agricultural Co. (Kansas City, Co.), incorporated under the laws of Missouri with \$100,000 capital. Organized originally to start a coffee plantation in the isthmus of Tehuantepec, their plans have been extended until they now include an offer of 100-acre tracks, one-half planted in coffee and pineapples, and 4,000 rubber-trees. The idea is to attract additional capital and increase the number of persons interested in tropical cultivation. They claim to have several thousand rubber trees on their lands already, and more will be planted. After eight years it is promised that the rubber-trees will yield yearly \$1 each.

A despatch appeared in the New York *Sun* of July 12, dated from Oaxaca, Mexico, saying: "The India Rubber Company of Mexico, an English corporation with a paid up capital of \$2,000,000, is going into the rubber industry in Mexico on an extensive scale. This company is now planting 5,000,000 rubber trees on their lands in the district of Pochutla, this state. They have 400 men at work on the land now."

Every increase in the demand for any grade of rubber tends to raise its cost to the manufacturer. Suppose, then, that certain African sorts should be found truly to yield a substitute for Para. How long would the present difference in price continue? There would be a steady rise in Africans until it would be economical no longer to use them instead of Para rubber. This consideration would soon put an end to any hope for great profits from substituting low-priced African gums for the higher priced sorts from South America. But it remains to be proved that the African rubbers are capable of such use as has been asserted. Of course great advance has been made in their manipulation, permitting their use in channels where, not so many years ago, it would have been impossible. It is reasonable to suppose that the use of Africans will continue to extend in new directions, but the experience of every manufacturer who has ever had anything to do with these sorts has helped to make him conservative.

It is not the question of how much rubber there is in Central Africa, or of how many laborers can be had. It is not even the question of transportation that is most important, but how the rubber is going to find a market. Para rubber always has been and always will be the mainstay of the rubber industry. There is a demand of course, for African rubbers, and this will grow, but from this time on it will be only in the same proportion as the rubber industry grows as a whole. When the limit to the demand for Congo—or any other—rubber has been reached, the production will fall off, and this is why I say

that we are not going to see such a great lot of Central African rubbers coming to market in the next few years as some other people think. Let the market once become overstocked with these grades, and prices will fall below the cost of producing and shipping them to market.

AMERICAN TEA IMPORTS OF 1897.

	Pounds.	Dollars.
The total imports of tea for the year ending June 30, 1897, were, from the countries named, as follows:—		
United Kingdom ..	6,212,008	1,165,765
British North America ..	2,547,371	396,738
China ..	56,483,924	7,281,931
East Indies ..	2,120,003	272,683
Japan ..	45,465,161	5,651,279
Other Asia and Oceanica ..	454,111	57,226
Other countries ..	60,597	10,240
Total..	113,343,175	14,535,862
Exports ..	439,577	98,790
Net imp'ts or cons'mpt'n	112,903,598	14,737,072
Net imports in 1896 ..	93,340,248

Increase ..	19,563,350
Consumption, 1897, per capita	1.55
Consumption, 1896, per capita	1.33

Tea is the most talked-about article in the grocer's stock, and yet the total import cost of one year's supply is less than \$15,000,000, and the retail cost less than \$30,000,000. The trade is insignificant in comparison with other articles consumed, and yet it absorbs more attention than any other one article. It has always had a historical interest, a social connection; been in favour as a stimulant, and of interest to the grocer because it is a medium for generous profits.

The net imports, reduced to gallons of beverage, show a consumption of not less than 561,517,990 gallons, on a basis of five gallons of beverage to one pound of leaf. Some claim that one pound of leaf makes six gallons of beverage. When India or Ceylon tea is used, one pound of leaf will make from twelve to sixteen gallons of beverage, showing it to be the cheapest good stimulant in favor with consumers.—*American Grocer*, Aug. 18.

THE TRADE IN ALOE FIBRE.

The *Indian Textile Journal* writes:—Few of our readers are probably aware of the increasing business that is now being done in the export of aloe fibre. There has been a continuous demand for the fibre from many parts of the world and it seems that if India can supply it in large quantities there will be a good future before those who will set to work and begin the export on a large scale. As it is, it unfortunately remains a neglected industry, in this country, but if once regular shipments are made and depended upon, a steady demand will be kept up. According to a correspondent, a visit to the press houses at Colaba would surprise many a capitalist in search of a profitable investment. Waggon loads of the fibre are sent down to Bombay from the growing districts by merchants or their representatives. It is forwarded either in bulk or in loose bales and on arrival is carefully sorted by the buyer, who fixes his price, which varies from R75 to R125 per ton according to the different qualities. It is then pressed into bales of the same size as cotton bales. The price delivered in London is reported to be from £5 to £17, so that a good margin of profit is generally left to the Bombay exporter.

India, like most of the Eastern countries possesses a great variety of fibres; but a very few of them are commercially useful. Aloe fibre grows wild in many part of India, the Bombay supply depending on the wild tracts of Central India, the whole of the Deccan and the Bombay Presidency, where on the coast of Katbiawar, and particularly in districts near Poon.

it grows in abundance. No systematic cultivation of the weed is yet attempted. Men, woman and children of the lowest caste pick the leaves in swamps and malarious bogs when they have no better occupation to follow. The work is alike unhealthy and injurious, as the juice of the plant causes itching of the skin, and in the case of sores of cuts the limbs have been known to swell. The families set to work in groups, and while some gather together the leaves and stems, the others strike the leaves, after they are dipped in water, against a stone, which operation separates the fibre from the leaves, juice, &c. This is the most primitive of the methods still followed in many districts, but of late several hand machines of somewhat crude design have been made by which the fibre is extracted. Having separated the fibre in this way, the natives attend the bazaar with their supply and part with their small bundles for a very nominal consideration in the shape of food grain or copper coins. The fibre is used in this country either pure or mixed with hemp or flax for making cordage, &c. America exports large quantities of the fibre to all parts of Europe, Mauritius being next in her supply. The plant in these countries is, moreover systematically cultivated, and the fibre being extracted by improved machinery, is commercially far superior to the Indian Aloe.—*Pioneer*, Sept. 9.

PLANTING AT THE STRAITS.

In the "Negri Sembilan Government Gazette" of Sept. 3rd, received today, we find the Report by the Commissioner of Lands and Mines (Mr. H. Conway Belfield,) F.M.S., dated Taiping, 23rd March, 1897, and from it we make the following extracts:—

SEREMBAN.—The progress of coffee planting by Europeans is very noticeable and satisfactory. Eight applications of this nature were registered during the year, and a total area of 4,133 acres was granted for this purpose. 6,977 acres were surveyed, and seven leases were registered for this purpose alone. The amount of quit-rent now paid annually in respect of large estates in the district owned by European planters is \$2,707.56.

PORT DICKSON.—One thousand eight hundred and ninety-two acres of land were alienated during the year, bringing the total on 31st December up to 49,393 acres, distributed among the following descriptions of cultivation:—

Gambier and pepper ..	23,353 acres
Tapioca ..	21,395 "
Coffee, kampong, and sawah ..	4,645 "

Ninety-one applications for land were received, embracing an area of 2,745 acres, and 195 leases were issued during the year. The concession of 11,000 acres of gambier and pepper land, granted in 1876 to Toh Eng Sew, for twenty years, fell in during the year, and the land reverted to Government.

JELERU.—The total amount of land alienated in the State for agricultural purposes on 31st December was 2,740 acres, of which it is estimated that about 2,000 acres is padi land. Of this quantity, 552 acres were alienated in 1896. The mining lands now occupied amount to 6,514 acres, 411 acres having been given out in the past year, of the above area, nearly 6,000 acres are held by the two companies above mentioned.

A CEYLON PLANTER REPORTING ON DOMINICA.

In the "*Colonies and India*" of August 23th we find the following reference to a Report presented to Mr. Philip Temple's Government by Mr. Naftel, so well-known here as a Pussellawa planter and afterwards *pro tem*, Visiting Agent to Messrs. Cumberbatch & Co.:—

We have received a copy of the report compiled by Mr. C. O. Naftel, late Inspector of Plantations in Ceylon, who, it will be remembered, was invited

by the Government of Dominica to inquire into the capabilities of the latter island. Mr. Naftel is eminently qualified to perform such a task, having had more than 20 years' experience of tropical agriculture in Ceylon, and his report is a most valuable and interesting document which, although it applies particularly to Dominica, may be found to furnish some useful general hints to planters in other parts of the West Indies. Mr. Naftel holds up the Ceylon system of cultivation as an example to Dominica, and, in writing this report, he has had before him the hope that means may be found to enlist the services of Ceylon men for Dominica. The question has been asked why the Dominicans do not take advantage of the natural resources of their island. The principal answer is that they have no capital, and though the planters are experimenting in new products to take the place of their old staple, sugar, they cannot do much without money. What are required to bring out the resources of Dominica are capital, cheap money, and experience obtained in more prosperous fields of enterprise. There is no doubt that Dominica offers a profitable field for an agricultural company, and in addition to their being a good opening for such a company there is one for men with the necessary knowledge and capital. Planters trauced in Ceylon have gone to the Straits Settlements, Borneo, and East Africa, to take up lands for Liberian or Arabian coffee. If others are meditating such a step Mr. Naftel advises them to look at Dominica first. There is no need to go so far afield and to bad climates, when, within a fortnight of England, there is this fertile island, possessing a climate difficult to equal, and certainly not to be surpassed by any place within the tropics. Mr. Naftel has seen enough of the island, and so compared its advantages with all that is considered essential for agricultural purposes in Ceylon, to induce him to confidently advise anyone with capital (which he can afford to invest without requiring an immediate return) and with knowledge of planting, or with confidence in some person whose services he can secure to plant for him, to invest in Dominica. It is to be hoped, therefore, that this report may bear fruit in the shape of attracting capital and fresh settlers to the island, the inhabitants of which, however, can greatly help to improve its condition by recognising and acting upon the recognition of the fact that what is worth doing at all is worth doing well, and that method counts for much, both in the eyes of capitalists and in the successful carrying out of even the smallest enterprise.

Not only coffee, but cacao and nutmegs are reported to do well in the West Indian island administered by the ex-Government Agent of the Central Province.

TEA PLANTING IN FIJI.

We find the following advertisement in the *Fiji Times* of 7th August:—

FOR SALE.—The Wainunu Tea Estate, consisting of 700 acres. 200 acres under tea, fully bearing, will produce 80,000 lb. of tea incoming season. The latest appliances for manufacturing and water power for driving. Estate thoroughly clean and all buildings in first-class order. Inspection invited.—Apply to, ROBBIE AND EVANS, Levuka.

And an editorial note referring to it is as follows:—

The Wainunu tea estate, it will be noticed in this issue, is advertised for sale. The property consists of 700 acres, 200 acres of which are under tea and in full bearing, while it is estimated that the mill will produce 80,000 lb. of tea during the incoming season. The mill has all the latest and most improved appliances for manufacturing, being driven by water power. All the buildings are in first class order and the estate is thoroughly clean. The Wainunu tea is well known all over Fiji and finds a ready sale in the group, and as the demand here is

nearly equal to the supply but very little has been exported, although what has been sent away has been reported on very favourably. Such an estate in Ceylon would be valued at from £80 to £100 per acre, for all the area under tea, so the planters in that island have evidently a high appreciation of tea property. The estate should prove a very profitable investment with any one with the necessary capital to carry on operations, not that the amount required would to our mind need to be very large.

We understand this Wainunu tea estate is the only one now in Fiji. If it were situated in Ceylon such a place would readily find a purchaser, but the scarcity and dearth of labour in Fiji will militate against it being sold for anything approaching a decent figure. Local sales of tea are the only thing to keep an estate going in Fiji, until labour conditions alter greatly for the better.

TRINIDAD AND TOBAGO.

From the report of Sir H. Jerningham on the condition of Trinidad for the past year, it seems that the revenue was £618,332—the largest figure reached for years past—and the expenditure £594,462. The public debt is £556,288, wholly incurred for railways and roads. The population is estimated at 248,404, of which East Indians number 81,404. The imports amounted to £2,463,525 and the exports to £2,165,820, of which about half in each case belongs to British countries. Sugar and its products, cocoa, asphalt, and bitters are the chief exports. The area of the colony is estimated at 1,120,000 acres, of which more than half remains to the Crown. The area under sugar cane is 58,500 acres, and cocoa 97,000 acres.

The Tobago report is also satisfactory the revenue exceeding the expenditure. The labourers, who are mostly peasant proprietors, are in comparative comfort. The larger landowners and merchants may feel the pinch of the times, but the labourer, with his small holding and his few head of stock, supplemented by occasional work on estates or public roads, finds his existence an easy one.—*London Times*, Sept. 3.

THE RESOURCES OF ABYSSINIA.

Ethiopia is a mountainous and very fertile country, the latter characteristic being especially true of the plateaus of moderate altitude (2,000 to 3,000 feet). According to the *Bulletin de la Société de Géographie Commerciale*, the products are barley, wheat, millet, maize, sorghum, flax, various oils, medicinal plants, potatoes, coffee, tobacco, sugar-cane, &c. There are vast forests; the sycamore, the mimosa, the tamarind, a variety of wild olive (reaching thirty feet in height), the lemon, the orange, and the coffee tree are among the principal species. The domestic animals are horses, donkeys, cattle, sheep and goats. Birds and bees abound. The latter contribute largely in certain districts to the wealth of the country, their honey being used in the preparation of hydromel, the favourite native drink, and the wax serving for candles. The mountains contain gold, copper, iron, and rock salt. Potter's clay is common, and in many places very pure. The principal articles of export are coffee, gold, ivory, skins, gums, wax and medicinal plants. The imports consists of cottons, silks, cloths, carpets, firearms, cutlery, hardware, provisions, and tools. The French colony at Obock has opened a route for commerce to Harrar and various provinces of the Empire. A postal service has been established between Djibouti, Harrar, Addis Ababa, &c., and there is telegraphic communication between the two latter places. In the interior,

the service is by horse; from Djibouti by boat. Addis Ababa, the capital, has a permanent population of some 50,000; the total number of inhabitants of the country is 15,000,000. Addis Ababa is an important centre of trade. Harrar is the residence of Ras Makonen; it has a population of 42,000. This is the point of transit of all the commerce from the southern provinces. The goods are brought to the city from the interior by mules, and carried thence to the ports by camels. The annual value of the trade of Harrar amounts to over £1,000,000, and is growing steadily. — *Journal of the Society of Arts*, Aug. 27th.

AREKAS—PLANTAINS—PLUMBAGO.

KEGALLA DISTRICT (CEYLON) AND ITS INDUSTRIES.

We have already reviewed Mr. Davidson's admirable Administration Report for 1896 on the Kegalla District; but it was so full of matter worthy of notice, that we could only give samples at the time. On next page will be found an extract supplying useful information bearing on the local industries in new and old products—in plantains (of which nearly 3,500 tons were carried from Rambukkana to Colombo last year!) as well as in arekanuts, Liberian coffee, cacao, and rhea. About arekanuts Mr. Davidson gives us new and valuable information accompanied by suggestions well worth the attention of the Government. He estimates the gross return from arekas properly planted at K90 an acre; and as the expense of upkeep and collection must be comparatively moderate, there would seem to be a margin quite as good as that in coconut palms. Mr. Davidson does not mention how long it takes to bring arekas into bearing; but from our own little guide for areka planters (out of type, but which we must at once reprint) we see the time required is five to six years only—a great advantage over coconuts. Curiously enough, Mr. Davidson's estimate of gross return (K90) agrees very closely with that of the late Mr. Borron (R87), although the latter, planting 10 by 10 ft. had far fewer trees to the acre. The natives, according to Mr. Davidson, would allow 1,200 arekas grow to the acre—far too many; but while he would cut this down to 750, Mr. Borron would have less than 500 arekanuts to the acre in order to do them full justice. The different views will be fully discussed in our little manual.

What we want to ask is why should every tea estate in the Kelani Valley not have its boundaries marked by areka palms? If there is room for a double or treble row (each tree 10 feet apart) so much the better. As a supplementary product to tea in the Kegalla district—the favourite home of the areka—there can be no better cultivation, unless it be pepper of which, however, Mr. Davidson says nothing, although it was the special staple of the district up to 100 years ago or so. The time has come when we must press on all lowcountry planters to give special attention to arecas, pepper and nutmegs.

In regard to plumbago in the Kegalla district, Mr. Davidson affords interesting information. The next time the Governor visits the valley, he should be taken over a selected areka palm grove; and down into a plumbago pit, if His Excellency would care to venture into the latter. We cannot help anticipating a considerable development of plumbago mining as certain to follow a Geological Survey. Mr. Davidson mentions one Kegalla pit which employs no fewer than 200 labourers!

CINNAMON: THE LAST LONDON SALES.

The particulars which have reached us of the last quarterly Cinnamon Sales, held in London on the 30th Aug., give no cause for anxiety regarding the position and prospects of one of the principal ancient staples of the Island. There were 1,289 bales offered, as against only 779 bales at the corresponding sales last year; and of these 1,120 were disposed of in the auction rooms, at rather better prices than prevailed at the May sales. It may be remembered that in May only about one-half of the large offering of 1,676 bales found buyers at auction; and fears were expressed that already the trade was being overdone, and that the better prices which obtained, consequent on a steadier demand, were leading to a rush. We worked out some figures in our article on those sales, published in June last, in which we showed a very large progressive increase during the past four years. We at the same time published an extract from the "London Commercial Record" which contained some pointed remarks on the probable effect of swamping the market with inferior spice, and drawing attention to the absence from the auctions of two of the principal buyers. We ourselves have more than once commented on the facility with which such an article as Cinnamon might be overdone—as indeed its recent history, when over-production led to an almost ruinous fall in prices, shows—and warned producers, both against any great extension of cultivation, and the shipment of coarse and adulterated qualities; but the article in the "London Commercial Record" seemed to us more partisan than judicial, and to express the views of one section of the buyers which was rather irritated at the departure from the older practices of the trade. However that may be, the sales now under review prove that the supply is not yet in excess of the better demand for the spice which has sprung up within the last two or three years; for the competition for the lots was free, and led to an advance of 1d and even 2d in some marks. As usual Goluva Pokuna heads the list, with its Firsts commanding 1s 7d, and one lot fetching as high as 1s 10d per lb., which quite recalls old days. Wester Seaton cinnamon realised up to 1s 4d, and J.D.S.R. 1s 3d; while the common kinds averaged about 11½d some marks fetching up to 1s. Nor was "unworked" spice neglected; so that altogether cinnamon proprietors are to be congratulated on the results of the last sales, and on the prospects before them. With all that, there is the danger of overproduction; and if all we have heard be true of large sales of seed for nurseries in the Southern Province, the next decade may witness an inevitable fall. Here is a statement of the exports to 14th September for four years:—

	Quills.	Chips.
1894	1,208,993 lb.	379,543 lb.
1895	1,346,298 "	478,048 "
1896	1,346,298 "	551,893 "
1897	1,656,057 "	726,404 "

It will be seen how large and steady has been the increase during the past four years.

PLANTING IN SEYCHELLES.—It might be inferred from our notes of yesterday that "800" feet was the present limit of planting in the island. Not so, coffee and even vanilla planters have gone up already to 1,600 or even 2,000 feet above sea-level. As much as 22s 6d net has been got for Seychelles Vanilla (ordinary,) in the early part of this year, and 30s for very fine samples,

LAND IN NORTH BORNEO.

Mr. A. E. Wright who represents some important Ceylon planters arrived here on the 15th August from Singapore and was the guest of Mr. H. Walker. He left for Lahad Datu on the 16th and on his return stayed at Government House until the 23rd, when he left with Mr. H. Walker for Kudat. He was looking for land suitable for coconuts, tea, coffee and cinchona and is reported to have been well pleased with some of the localities he visited.—*North Borneo*, Sept. 1.

ARECA PALMS; PLANTAINS;
PLUMBAGO, &c.AGRICULTURE AND MINING IN THE KEGALLA
DISTRICT.

(From Mr. W. E. Davidson's Administration Report for 1896.)

What we ask from the

AGRICULTURAL SCHOOL

and the Royal Botanical Gardens is (1) that the Superintendent and Director should guide us when we want information; (2) that we should be supplied with seeds and young plants when we want them; and (3) that the Superintendent of the Agricultural School, or a really competent assistant from the school or from Henaratgoda or Peradeniya, should deliver special popular lectures on any new garden development. *E.g.*, this year we want in Four Korales to have all the information we can get on (1) the growing and preparing of rhea fibre; (2) the preparation of the tanning material in the green arecanut, and an analysis of the increased profit to be derived from preparing the product locally. Again, this year and next in Three Korales I want the whole country to hear all the facts and figures about plantain culture, so as to have their produce properly cultivated and ready for the railway to carry it to the market. If Mr. Driberg can prepare popular lectures on these points with limelight illustrations and such-like attractions, I will guarantee to find twenty audiences in selected neighbourhoods, and the net advantage to the country will in one season exceed all the advantages derived from any attempt at local school training. In fine, from my point of view the one benefit derivable by this district from the appointment of an Agricultural School in Colombo is that the Superintendent, or a competent assistant, should deliver locally popular lectures on popular subjects. He should fulfil the same functions as are discharged by a "County Council" lecturer, *e.g.*, as in Sussex.

The subject is fully discussed in my reports of the 2nd December, 1895, and of the 16th February, 1897.

NEW PRODUCTS.

In the same reports I have reviewed the history of the attempts to introduce new paddy, *e.g.*, muttusamba pulukhamban, and Carolina, and of barley; of new garden fruits such as pomegranate, Mandarin orange, Madagascar papaya, pomeice, loquat, jambu, guava, and the Cochin geraka; and of new commercial products, such as tea, Liberian coffee, cacao, cotton, cloves, pepper, and rhea fibre. The growing of rhea fibre promises to develop into a cottage industry.

In a fertile, highly cultivated district like the Four Korales a great deal depends on facilitating the transport of surplus produce to the best market, and in this direction my own efforts have been specially directed by opening out feeders to the railway and constructing bridges and developing paths into roads fit for wheeled transport. In this way the area upon which plantains can be profitably cultivated has been greatly extended.

Following up the detailed account of the plantain industry given in the 53rd paragraph of my report for 1895, I furnish in the next paragraph a few particulars of general interest regarding *arecanut* cultivation. I may record here that the plantain industry around Rambukkana is still growing fast, and that the railway carried 3,481 tons of plantains from Rambukkana to Colombo, earning thereby freight charges amounting to R19,319-55. This local industry will reach its culminating point about 1,900 and will

then fall away owing to want of further suitable soil. I hope that the cultivation of rhea fibre—well-suited to village ideas—will step in to take its place.

The *Arecanut palm* flourishes throughout the Kegalla District most luxuriantly. Although it grows freely over a limited range in other districts and countries, yet, as almost the sole source of supply to Southern India of what the Indian races look upon as a necessary of life, the arecanut trade of the Kegalla District has for generations represented one of the few agricultural monopolies of the world. The produce of the arecanuts of Four Korales was the backbone of the King of Kandy's revenue; and the Dutch Government on the coast used, whenever occasion arose, to put pressure on the Kandyan King by blocking the export trade at Puttalam and Kalpitiya and stopping the importation of salt in exchange.

Arecanut palms, if left to seed as they please, grow as densely as 1,200 to the acre. This is often the density in the village Aramba; and then the average yield per palm is 80 to 100 nuts. If, however, the palms are planted (as is generally the case now) at 750 per acre, they practically double their yield. A fair crop is 120,000 nuts per acre, and 24,000 dried arecanuts go to the amunam, which is the standard measure of the trade. The weight of an amunam of dried nuts is 2½ cwt. The yield therefore may be calculated at 12½ cwt per acre. An amunam of dried nuts sells on the spot at from R12 to R24 according to the market demand and the facilities of transport. The present average rate is R18; it seems to me probable that high prices will be again reached owing to a quantity of the crops being sold when unripe as sliced arecanuts in order to meet the demand of a new market. The gross average return per acre would be about R85 to R90. An experiment in which 250 palms only were planted in an acre resulted in an average yield of 750 nuts per palm, or 187,500 nuts per acre. This is equal to about 8 amunams per acre, or nearly a ton in weight, with a gross return of R144 per acre. The yield of the Madras Presidency estimated at 3,000 tons off 1,600 acres, is manifestly inaccurate. The area under arecanuts in the Kegalla District is 24,749 acres, rather less than one-half of the total acreage under the arecanut in Ceylon. The yield is 15,469 tons in weight, and that of the whole Island at perhaps 25,000 tons, of which about one-fourth appears scheduled in the Customs returns as exported to India or Mauritius. It is probable, however, that the weight of the produce has decreased before export, and that the quantity exported considerably exceeds one-fourth.

The growth in the demand for "kalli pakku"—the sliced green arecanut—has been very marked in the past few years, and it is now most profitable to dispose of the crop while still green and unripe. It is used in South India, I am informed, to tan leather, chiefly sheep skins. But it is generally boiled down and made into a kind of "kaipu," and in its prepared state finds its way to Bombay and is shipped to Europe. It has been suggested to me that the Government should send a trained agricultural student to the coast of India to ascertain the processes through which the prepared produce passes, the prices current, the ports of destination, and the uses to which it is eventually put.

PLUMBAGO.—I here follow up the theme touched on in the 54th paragraph of my Administration Report for 1895. A professional miner, who has been appointed Inspector of Mines under the provisions of Ordinance No. 2 of 1896, has made a thorough inspection of the plumbago pits in this district and reports highly as to their prospects, which he considers equal to any in the Island. Of the 18 pits now open and working, 10 are situated in Belgal Korale, 4 in Paranakuru Korale, and 4 in Three Korales. In Belgal Korale is the deepest perpendicular shaft in the Island, 323 feet deep; and at another pit there was on the day of his last inspection a force of 201 labourers, the largest force at any one pit in Ceylon. The average number of miners employed is a little short of 1,000 men. The condition of the timbering is generally

excellent, and the cooly lines, where such are required, are fair; the checkrolls seem kept in a business-like way, and there are no complaints as to the non-payment of wages. The labour shifts—24 hours—are too long for efficiency one would think, yet the arrangement is popular with the men, who like to have a day on and a day off. Nearly all the pits are sunk by perpendicular shafts, which are the most economical to work and the safest to work in. Two fatal accidents were reported during the year: one from the falling in of earth in the only pit which consists of an open cutting, and one in hammering a blast.

The output for 1896 is estimated at 1,516 tons, worth at the pit's mouth R196,305. The following are the figures, which are based on imperfect information, for the last four years:—

	Tons.	Value.
1893 ..	3,520 ..	R. 422,400
1894 ..	1,875 ..	163,220
1895 ..	2,254 ..	225,400
1896 ..	1,516 ..	196,305

MINOR PRODUCTS TRADE REPORT.

Sept. 2.

CARDAMOMS.—The supply was again moderate and with an active demand; the whole sold, on the average, at an advance of about 2d per lb.: good bold pale Ceylon-Mysore realised 3s 10d per lb.; medium ditto, 3s 4d per lb.; small ditto, 3s per lb.; medium splitting, 2s 9d to 2s 11d per lb.; brown splits, 2s 7d per lb. Seed sold well at 3s 1d per lb.; for good, down to 2s 9d to 2s 10d for pale. The arrivals last month were 160 cases, deliveries 303, and stock 862 cases, as against 426 same time last year.

CINCHONINE.—Howards' sulphate has been raised to 4½d per oz. in bulk vials 5½d for not less than 25 oz.

COCA-LEAVES.—At auction 20 bales of Truxillo and Bolivian were offered and bought in at 6d per lb. The following figures relate to the Java export of coca-leaves for the last four years from July 1st to June 30th:—Bales 1896-7, 1,067; 1895-6, 1,105; 1894-5, 1,121; 1893-4 362.

CROTON-SEED.—Seventeen bags were shown today at auction; 10 of these, poor and dark mixed, were bought in, there being no bid at 30s. Of another lot of 7 bags, 4 sold at 50s per cwt, subject to approval the remaining 3 being bought in nominally at 80s per cwt.

OILS (ESSENTIAL).—There is a fair amount of business doing in essential oils this week, but there are no changes in price to report. Cassia is without alteration; business has been done at 5s 1½d per lb, c.i.f. terms, for 80 to 85 per cent. Oil of cubebs is offering at 4s 3d per lb., 8 cases of Cinnamon oil were bought in at auction at 5d per lb. About 100 cases of Eucalyptus oil were offered today, but nothing was sold. For 17 cases, commercial quality, a bid of 10d is to be submitted; 16 cases from the Macedon Eucalyptus Oil Distillery Company, Macedon, Victoria, were bought in at 2s 1d per lb. Other lots were bought in at 1s per lb for fair commercial quality. Nutmeg oil: Seventeen cases were offered, but nothing sold; from 2½d to 3½d per oz. is asked.

QUININE.—9½d per oz. still remains the nominal quotation, though we hear that business has been refused at this figure for a speculative order of 10,000 oz. Wholesale druggists' orders are being filled on the spot at 9½d per oz. At auction today 1,000 oz. of Tallandier's brand, in 100-oz tins, were offered at 9½d per oz, without finding a buyer. The arrivals last month were 2,686 lb, with deliveries 4,082 lb, and stock on August 31st, of 85,566 lb, as against 99,098 lb same time last year.

VANILLA.—At auction, 153 packages were offered. Of these 120 sold, common foxy, 3½ to 8 inches, 11s to 21s 6d; bad-keeping 6½d to 8½ inches, 23s 6d to 26s; fair dull to good chocolate, 3½ to 8 inches, 21s 6d to 26s; fine fresh chocolate, 6 to 8 inches, 26s to 27s 6d. —*Chemist and Druggist, Sept. 4.*

CEYLON TEA COMPANIES:—DIVIDENDS AND "RESERVES."

We happened to be in Scotland when the City of Glasgow Bank came down, and witnessed a scene of unexampled financial excitement and disturbance. We recall, too, the deliberate opinion of a shrewd old private capitalist who had prolonged experience as an investor and who was a great authority on share-lists. "Of all home investments" —he said—"my favorites are Railway shares. Railway Companies furnish their reports and accounts in such a way that each shareholder cannot fail to understand exactly his position at the end of the twelve months, and he gets such dividend as the earnings justify, no more and no less. There is never any question of keeping bad debts out of sight, any more than of laying by nest-eggs for the future."

We are reminded of this praise of the accounts of British Railway Companies as, in their system of financing, models for all Limited Companies to follow, by the criticism in which our evening contemporary has once more chosen to indulge against the Directors of local Tea Plantation Companies, Limited. This criticism strangely enough is directed against local Directors for following the example which was held up to us well-nigh twenty years ago by a shrewd financier as the very best model that could be followed. But whether this be the best model or not, any one who has thought on the subject must realize that there is a great difference between the case of shareholders resident and at work in Ceylon—as most of the holders of rupee shares are,—and the average of shareholders in home sterling Companies. Here, shareholders almost to a man do not want their money to lie in reserve; they prefer to get a full share of what is earned, in order to utilise and, if possible, turn over such profit on their own account; and we cannot therefore see any fault to be found with local Directors for doing as their shareholders desire. The latter know exactly how they stand and if they are wise, they take steps against the evil day of lower dividends—fully anticipated for some years in the face of the steady fall in the price of tea —by further investments on their own account. But we are not trusting in this matter to our own inferences and authority: here is the opinion of a leading Colombo merchant who has had as much to do with successful Tea Plantation Companies as any man in the place:—

"With regard to forming Reserve funds for the equalization of dividends, I look upon 'H.H.C.'s' effusions in the local 'Times' as all 'Tommy Rot' so far as Ceylon Companies are concerned. At home, where many of the shareholders may be persons totally unacquainted with the working of tea properties and perhaps looking for a steady income from their investments, Directors are no doubt wise in exercising a maternal care for the interests of their clients. You will not find that, in such concerns as Railways, which the British Public understand, this practice obtains. Shareholders in these Companies, I think, get as large dividends as can well be divided and consequently suffer or gain according to the returns of the year, and the value of shares fluctuates correspondingly. The origin of local Tea Companies was to enable people with a little spare cash and with faith in the future of tea, to take a limited interest in such ventures. A very large majority of the shareholders in local Companies

know quite well what they are about, and are not so idiotic as to expect the same return from their investments when the tea average is 7d and exchange 1s 4d, as with tea at 9d and exchange 1s 1d. The value of shares necessarily fluctuates with the price of tea, and a Reserve Fund to equalise dividends would not prevent this. Annual balance sheets are carefully examined and reserves are taken into consideration by purchasers of shares, but as soon as it becomes necessary to use such reserves for paying dividends, shares will fall in value. I am strongly of opinion that profits should not be reserved for future dividends, but that shareholders should have the choice of doing what they please with the annual earnings. Many may wish to 'average' their investments by putting the money into coconuts, hotels, &c., or into sterling concerns, instead of having it invested for them in a Bank at a nominal rate of interest. At the same time, unless a Company is fully capitalized, I am no advocate for dividing profits 'up to the hilt.' Almost every property acquired is in need of development, and if the subscribed or paid-up capital does not provide for the cost of such development, as well as for outlay on coast advances, &c., then by all means let the Directors reserve part of the profits to cover such excess expenditure. It may even be advisable in some instances (alas, that it should be so!) to have a cash reserve to carry on with, when the price of tea is so low as not to cover cost of production."

PURSLANE, A "BOTANICAL WONDER."

The common purslane (*Portulaca oleracea*) is one of the wonders of botany, as far as seeds are concerned at least. A single seed of this plant will produce about 20 seed-pods in a season. The average number of seeds in each of these, by actual count, is 6,000, making 120,000 in all. As far as we have been able to learn, there is no instance of similar fruitfulness in any plant found growing in this country. A single plant of either the Jamestown weed ("jimson"), the butter weed, the rag weed, and some of the vervains produce an enormous number of seeds; but it is doubtful if any one of them produces one-fourth as many in a year as the purslane does.

COFFEE-PLANTING, LAND AND AGRICULTURE IN SELANGOR.

(From Mr. Rodgers' Annual Report.)

EUROPEAN ESTATES.—The chief cultivation was that of Liberian coffee, both by Europeans and Asiatics, and the cultivation of this product was extended in every district of the State. The number of plantations owned by Europeans now amounts to seventy-two, comprising approximately an area of 47,000 acres, of which 10,835 have been cleared and cultivated. The labour force employed consisted of about 4,000 men, chiefly Tamils and Javanese. I am glad to be able to record that several Ceylon planters, among whom was the Hon. T. N. Christie, the planters' representative in the Council, Ceylon, took up land in Selangor during the past year. The whole of the land selected by these gentlemen was in the Klang district, but some of it was situated at Damansara, a place 16 miles inland from the coast.

NATIVE HOLDINGS.—The area held by natives approximately amounts to 60,000 acres. The cultivation of coffee has largely increased, but that of rice, and other products of tropical agriculture, has made comparatively little progress, and still leaves much to be desired. Regulations are now being considered for ensuring the simultaneous planting of rice, so

as to minimise the damage caused to the crops by wild pigs, rats, etc., and the whole question of the best means to encourage and assist native planters is one of which should be taken into consideration at the first general conference of Federal representatives.

COFFEE CURING.—There is a small coffee-curing establishment at Klang, now owned by a Chinaman, which is of great use to native planters in the neighbourhood, but it is to be hoped that some firm of European merchants will soon see their way to establish a factory on a large scale, either in the Colony or Federated States, to which European coffee planters will send their produce to be treated, as is the practice in Ceylon. The export of coffee increased from 5,395 cwt. in 1895 to 8,388 cwt. in 1896.

PLANTERS' ASSOCIATION.—The Selangor Planters' Association has given valuable assistance to the Government, and its Chairman, Mr. E. V. Carey, was selected to represent the State on the Labour Commission. The various local associations have now been amalgamated, and a central association has been formed, representing the planting interests of all the Malay States.

NEW PRODUCTS IN THE KELANI VALLEY (CEYLON).

With reference to our remarks on another page, we are able to quote the views of a proprietor as follows:—

"(1) Arecas don't pay. I think that where they are grown on tea estates (and there are several estates which have them) the coolies are allowed to gather the nuts for themselves.

"(2) Pepper and nutmegs are troublesome subjects and Superintendents with the careful attention they have, or ought, to give to tea have not the time to devote to their successful cultivation. I do not think that these minor products can be made to pay (in Ceylon) the value of European supervision!" This simply means that tea, even now, is too profitable to make it worth while to attend to minor products. Should misfortune overtake tea, the case will be very different! After coffee failed in Ceylon, business in vegetables and milk and butter even was not despised by upcountry planters. It would be well, therefore, to keep planting arecas and nutmegs in the Kelani Valley against the chance of an evil day to come. The coolies can soon be taught not to steal when they see the durai in earnest about his crop; while as regards the trouble involving in growing and cropping the pepper-vine and preparing the product, all this is as nothing to the trouble taken over tea—at one time thought to be far beyond the Ceylon planter and his coolies. Surely one or two coolies, well up in "pepper," could be got down from that part of Southern India, which supplies for export some 222,383 lb. of pepper every year; while the export from Ceylon once considerable has dwindled to a mere trifle.

BRITISH NORTH BORNEO.

(Wednesday, September 1.)

RHEA cultivation has, we may note, just been commenced in the Suan Lambah district. Several thousand plants have been put in. People desirous of seeing the beautiful fibre it produces with specimens of cloth, canvas and belting manufactured from it, can do so at the B.N. Borneo Museum.

We hear that Mr. Hastings has had some good plants of tobacco raised on the Areudberg Company's ground near Tawao, in view of that Company's early opening of an estate there. The tobacco is reported to have grown well and to be very fine. The Company will commence work in September. A commencement has also been with made the necessary buildings.

PLANTING NOTES.

TROPICAL FRUITS.—It is surprising we do not see more tropical fruits in the markets. What would attract more attention at large dinner-parties during Christmas-time than a dish of Custard Apples or Avocado Pears? They would add the variety and change so much needed, the flavour is so unlike that of our own native fruits. The two fruits mentioned I can recommend as being very palatable. The Melon-Pear, frequently seen two or three years since, has not gained favour in this country. The Loquat (*Eriobotrya japonica*) I am not acquainted with. I had a large plant, but was not successful in fruiting it, I should be interested to know if it has produced edible fruits in this country [often]. W. H. Clarke, Wellington, Somerset.—*Gardeners' Chronicle*, Sept. 4.

LOCAL TEA COMPANIES AND RESERVE FUNDS.—In his rejoinder to recent criticism our evening contemporary takes special care to ignore the all-important reason given by a mercantile authority and ourselves for the course pursued by the Directors of Rupee Tea Companies with the full approval of their shareholders. The latter being nearly all in the Colony and busy on their own account, did not—and do not—want their money locked up in a reserve, lying idle at the bank; but preferred to get a full share of their Companies' earnings, in order to invest on their own account. For our contemporary to pose as superior in sagacity and business aptitude to the mass of the Directors and shareholders in local Companies, is rather ridiculous!

VANILLA CULTIVATION IN SEYCHELLES.—Government House, Seychelles, Sep. 25th, 1896. Sir,—I have the honour to report that the result of the Vanilla crop for this year is most satisfactory. The crop up to the present (it is not quite gathered) is returned at 40,000 lb., and has realised over half a million. The prices have been exceptionally high owing, I am told, to a reduced exportation of Vanilla from Mexico. Seychelles Vanilla is now well and favourably known both in London and Paris markets.—I have, &c., (Signed) H. COCKBURN STEWART, Administrator. To the Right Hon. Joseph Chamberlain, M.P., &c. &c. Extract from Colonial Reports. Annual. No. 182. Seychelles. Annual Report for 1895, p. 9. Next to coconut oil Vanilla is our most important produce, and in a good year the crop gives a return of about R400,000. Unfortunately vanilla is a most capricious plant, and, whereas we may have a good crop for two consecutive years, we may have also three, or even four, years without any crop at all.—*Kor Bulletin*. [One planter gets as much as 80s or 32s 6d per lb. for his Vanilla. For 1897, we believe, the crop will not exceed 25,000 lb.—ED. T.A.]

LONGEVITY OF SEEDS.—Botanists, who have reason to revere the name of de Candolle, will read the following note with sympathy, not only for its intrinsic interest, but also as the production of one of the fourth generation of this famous botanical family. M. Auguste de Candolle, who now writes to us, is the great grandson of Auguste Pyramus de Candolle, who died in 1841. With reference to M. Ch. Naudin's paper on the longevity of seeds and their preservation in the earth, referred to in a recent number of the *Gardeners' Chronicle*, the following facts may be of interest. Some time ago, I was put in possession of some earth which had been dug up in Peru, near the Amazon River. Less than four days after the earth had been placed in two large germinating pans in a hothouse, a species of grass began to spring up, which proved to be *Eleusine indica*, Steud., and of which I subsequently counted over a hundred plants. I also detected *Vandellia crustacea*, Benth., a Spurge, and a species of *Verbenaceae*, perhaps new. These species all flowered and produced seed in due course. No doubt, with proper care, and had the *Eleusine* been kept down, many more distinct species might have been reared. *Aug. de Candolle, Geneva.*—*Gardeners' Chronicle*, Sept. 4.

NEW GARDEN PLANTS AT KEW IN 1896.—*Kendrickia Walkeri*, Thw. (*G.C.* 1896, xx., 394.) *Melastomaceae*. S. Described as one of the most beautiful of Ceylon plants. It is a climber with creeping ivy-like stems, ovate fleshy grey-green leaves and terminal umbels in large bright red flowers. Ceylon. (Kew.)—*Kor Bulletin*.

THE MANUFACTURE OF PICRIC ACID.—On Saturday, at the Dartford Petty Sessions, Mr. Bruce, on behalf of Messrs. Wallace & Co., manufacturing chemists, of Fenchurch Street, London, E.C., gave notice of an intended application for permission to make picric acid at their works at Crayford. Mr. Bruce stated that the acid is largely used in the manufacture of explosive, and at present is only made in Germany. The Bench fixed October 9th for hearing the application.—*Chemist and Druggist*, Sept. 4.

THE FORESTS OF INDIA.—Few people have any idea of the immense forest area in British India—a valuable asset which is now being systematically conserved. At the present time the reserves of forest cover an area of nearly 75,000 square miles, and they may hereafter be further extended in Madras and Burma, where the work of reservation is as yet incomplete. Outside these reserves are about 56,000 square miles of State forests some part of which will be brought eventually within the reserve area. This means that there are in India, practically for all time, forests which would completely cover the United Kingdom.—*Daily Chronicle*

CRUELTY, COFFEE AND RUBBER IN THE CONGO FREE STATE.—The following in *The Century* for September is from the journal of the late E. J. Glave who crossed Africa in 1895:—

There is good ground for coffee at Stanley Falls, where it grows prolifically. The station is on the north bank, just below the rapids and falls. In former times the station was on the south bank, but the tendency with the Arabs has been to the other side of the river. All ivory and rubber comes to the station of the Congo Free State. No matter how wide a road you make, the natives soon have in it a tiny foot-path, and tramp one after another in single file.

The state conducts its pacification of the country after the fashion of the Arabs, so the natives are not gainers at all. The Arabs in the employ of the state are compelled to bring in ivory and rubber, and are permitted to employ any measures considered necessary to obtain this result.

Mr. Glave died just at the conclusion of his expedition, May 12, 1895, at Matadi, near the mouth of the Congo. Shortly after his arrival at Matadi, he wrote a letter to the President of the Century Co., dated April 25, 1895, in part as follows:—The administration of the Belgians is decidedly progressive. Five large, comfortable boats have replaced the tiny A.I.A. "Royale" and "En Avant" on the upper river: a reliable postal service has been established to the very limits of the state territories; the Arab slavers have been crushed beyond ever again being a menace to the state's authority; and the Congo Railway, already running over a well-laid track for sixty miles, promises completion in three years' time, provided sufficient funds are found. This line will of course supersede the miserable depopulating system of manual transport by the native porters (the Bakongo), and will, when finished between Matadi and Stanley pool, bring the heart of Africa within easy reach of the markets of the world by steam communication. The state intends also to carry a telegraph line from the coast to Tanganyika, and operations are already begun. Coffee of a superior quality has been found to grow out here in nearly every district, with most promising results; and, to my mind, coffee and rubber will constitute the main articles of profitable export. Ivory is getting constantly scarcer, and in a few years' time trade in elephant-tusks will have yielded up its important position in the list of African products.

"HOW TO ECONOMISE THE AVAILABLE LABOUR SUPPLY ON OUR TEA PLANTATIONS."

REVIEW OF LETTERS XVIII. TO XXVI.

The nine letters now under review cover a very varied range of districts. "W.J." from the low-country, who has also had long experience up-country, is followed by "G. D. D." from a high district, and by "S." from a mid-district. The first has had no practical experience of shoots, and as he left the hill-country before the era of tea, he excuses himself from offering any opinion on shoots, tramways, and other labour-saving appliances. "G. D. D.," though also without personal experience of shoots, has seen them at work, and though they are said to damage tea leaf, he cannot understand how that can possibly equal the compensating advantages. For firewood they are undoubtedly useful; but tramways would be difficult to work on steep places and too expensive on most estates. Telephones, tavalams, wire tramways, cart roads, and carts in the lowcountry, are the labour-saving appliances which must be requisitioned according to special circumstances. "S." knows that shoots work satisfactorily, and think, they should be used more largely; but he counsels less costly or more lasting "runners" than those now in use, which are a great source of expense. "B. W." from the lowcountry, while asserting the undoubted usefulness of shoots for downhill loads, expresses his preference for wire tramways for leaf, as they save crushing and damage, and can further work up-hill. He has experience of a 2 ft. tramway on the estate from which he writes, and finds that it saves a lot of labour, as a car fully laden with 4,000 lb. of leaf can be moved by four coolies. "Engineer," with experience of erection, supports the previous writer, as regards both shoots and wire tramways, and thinks they can be much more largely used than they are, as they effect an immense saving of labour; and the former need not damage tea leaf, if stretched at an easy gradient. His opinion coincides with that of most planters, as to the inability of the average estate to afford a tramway; but he believes that water-power might be far more largely used than it is—many estates using a steam engine all the year round, which might well utilise water 8 to 10 months in the year at a great saving of cost. "K. V."’s incredulity as to the fitness of shoots for the economical transport of leaf should cease in presence of the body of evidence in their favour; but he believes in them for fuel, though not in tramways on the ground of cost. "Lunugalla" has had no experience of labour-saving appliances for transport, but thinks trams should be useful where manuring is done to any extent. This opinion is not shared by "G. J. R." from a high, and "W. M. U." from a low district, both of whom are in favour of shoots and aerial tramways; while the latter favours narrow hand-carts as a means of saving the coolies the carrying of tea chests, which is work they detest.

"W. J." is in advance of many, perhaps most, of his brother-planters in believing that weeding is being overdone. His difficulty lay in finding a weed which would protect the

ground and save wash without being injurious to tea and coffee. The entrance of grasses would have to be guarded against: mosses would not grow below 4,000 feet—is he sure of this?—and even if an imported plant of very low growth be found he questions whether there can be any real saving of labour. He is also entirely against any digging in of crops grown for that purpose, as the loss of soil would more than counteract any benefit from aeration on even moderately steep land. He is supported in this view by "G. D. D." and also by "S.," both of whom favour clean weeding; and the latter has special experience of a moss-grown patch on his estate, which at once responds, now in tea, as it did when it was under coffee, as soon as light and air are admitted to the roots by the use of the "karandy" on the moss. We can quite understand this result, especially in damp situations where the soil shows a tendency to sourness; while, perhaps, in soil without such tendency moss will not thrive. And this view finds favour with "K. V.," who, while holding that moss does not seem to do harm, has found that it will not grow on some spots. On the other hand, he does not think weeding overdone; but he desiderates, what would be priceless, a plant which, while thickly covering the ground, would take little or nothing out of it! Considering the general poverty of our soils and looking to the importance of preventing wash, he would neither grow a second crop nor dig it in. "W. M. U." sares this view, while holding that weeding as practised now is underdone, rather than overdone. He would clean the land thoroughly to begin with, and thereafter never allow weeds to grow to the extent that would cause disturbance of soil for their removal. Mosses he would not disturb, as they go off when heat and drought supervene. "Lunugalla," too, favours mosses, and objects to mamoty weeding, and so does "G. J. R." who pronounces, from long experience, that weeding cannot be overdone, and considers selected weeding next to impossible. "B. W.," however, always encourages mosses, &c., as soil binders and thinks cutting down weeds the correct and scientific way of treating them and the soil.

On Drainage all our correspondents are pretty well agreed—that the drains should not be too far apart, nor the gradient too steep. Few have yet made the acquaintance of cuscus; but those who have tried it, like it. Terracing is considered the ideal provision against wash, but the cost is prohibitory over any considerable acreage. Hand-carts as auxiliaries to transport are recommended by more than one Planter, because they would obviate unpleasant work for coolies who, in the opinion of two very experienced and observant Colonists, should be encouraged to make the existing labour supply go as far as possible by santosums to men who work 24 days at least in the month. The idea is an excellent one; but the gift should go direct to the worker, so that he might feel himself independent, to its value at least, of the Kanganu who generally appropriates all he can of monthly balances for debts, real or fictitious.* The

* If it were possible to get Ramasamy to bank such surplus cash either at the Post Office or with his employer, a great advantage in starting him on a course of thrift would result; but we fear the time has not yet come for a move of that kind, however desirable.

influence of vegetable gardens to bind the cooly to the estate is very freely admitted; but any interference with his liberty to roam to whatever boutiques he pleases for supposed bargains in curry stuffs, is depreciated; and there is much in the suggestion that estate caddies are often the home of illicit trade in arrack and the destination of stolen estate produce. Ramasamy's weakness for a drop too much when he has a chance is a sad, but not unique, feature in his character, but far better a licensed tavern than contraband trade.

(Letters Continued.)

No. XXVII.—HIGH DISTRICT.

(1) Have used wire shoots for manure, firewood grass, &c., but not for transporting tea leaf; they save a deal of labor.

(2) ————

(3) Have had no experience.

(4) It has often struck me that weeding was overdone, but, as a rule, our hilly land would suffer from any other kind of weeding.

(5) Selected weeding might be tried with advantage, but less frequent weeding would be a mistake.

(6) Have not experimented in this way.

(7) The present system of drainage is not satisfactory, but I doubt if it can be improved on at a cost that would pay.

(8) ————

(9) Good gardens make coolies more contented, as a rule.

(10) This might be advisable on outlying estates.

(11) Liquor shops to sell by the glass might be done away with altogether, with advantage.

C. A.

No. XXVIII.

(1.) No experience.

(2.) I have not seen anything beyond what is usual in all well-equipped factories and estates.

(3.) Very doubtful, except in very exceptional places.

(4.) Weeds are pernicious wherever met.

(5.) One argument in favour of clean weeding, is the saving of labour; coolies are generally more content on a clean estate.

(6.) No.

(7.) A good deal more might be done in draining, both by having drains closer, and a system of silt traps; tea apparently feels

(8.) Wash more than coffee.

(9.) A present of a Spinning and Weaving Co.'s cloth every 6 months to all good pluckers, and once a year to everybody on the estate.

(10.) Private Bazaars are good and they help to control illicit arrack dealing.

(11.) It is not so much the liquor shops as the enormous amount of illicit dealing that we have to content with.

(Signed) DIMBULDANDAOYA.

No. XXIX.—MEEUM DISTRICT.

(1.) Wire shoots can be used with advantage for shooting down tea leaf or firewood to the factory on estates where the land is steep.

(2.) I consider a tea-packer to be a considerable saving of labour in the factory.

(3.) Have had no experience of tramways, but should doubt if they would pay on most estates with labour at present rates.

(4.) } I think selected instead of thoroughly clean weeding might be a good thing, but doubt if one could get coolies to carry it out properly.

(5.) Have never tried the experiment and can give no opinion on it.

(7.) Yes, if carefully and thoroughly done. In steep stony land I have put terraces at an almost dead level right across the hill-side instead of drains and found the system answer well.

(8.) ————

(9.) I think it is a good thing to let coolies have gardens round their lines, but it is worse than useless trying to be *generous* to them. Give them good and sufficient line accommodation and treat them *justly*—but try and attempt nothing further.

(10.) It is a good thing, I think to prevent coolies going into the towns for rice, &c.

(11.) Yes, the liquor shops are a great source of trouble, but it is hard to know what to suggest except possibly that every liquor shop should be licensed directly from Government and the present system of arrack renting done away with.

E. W.

No. XXX.—LOWCOUNTRY.

(1) Yes. Not if properly erected.

(2) ————

(3) No I do not think so. I believe that with rather broader roads cut, leaf carts drawn by bullocks is the cheapest method for transport of leaf to the factory.

(4) No. But too much "scraping" is done.

(5) I think shade trees such as Albizzia stop a good deal of wash.

(6) ————

(7) ————

(8) A really good machine for tea-plucking.

(9) Gardens. Cows and goats.

(10) Most of the kanganyas and many of the coolies have been on this estate for twelve years, and seem as a rule contented.

(11) There are several arrack shops, but we have very little trouble from them. The illicit selling of toddy etc. by the villagers does more harm.

LOWCOUNTRY.

No. XXXI.—HIGH DISTRICT.

(1) I believe in wire shoots and think on many estates they could be used and save a deal of labour; if properly erected they do no harm to leaf.

(2) Saws (circular) for cutting firewood could more extensively be used.

(3) No, I do not think so.

(4) No.

(5) No.

(6) No, I should not advise such an experiment.

(7) Drains are generally cut at too steep a gradient which causes loss of soil. But if cut at say 1 ft. in 25 to 30 feet I find they stop wash well and the soil except in very heavy rain is not wasted.

(8) In getting larger averages of leaf per cooly; but as the labour in Ceylon now is so utterly demoralized, I fancy this cannot be done.

(9) I do not think they want any.

(10) No.

(11) Very much so and if there were $\frac{1}{2}$ the amount of liquor shops, our coolies would be certainly better I believe.

In reference to my answer to No. 8, coolies now do at most $\frac{1}{2}$ the work they did (per day) 18 years ago and the average per cooly in plucking leaf is very much less in the last 8 years, in my idea and my experience extends over 20 years of planting life. I am of opinion, that our coolies now, are half useless—and what is the cause of this? Years ago one never heard of a cooly taking his master to Court. Now the exception is the other way. If you gain your case in the Police Court, it's one thousand to one, you get it upset in appeal, and the cooly soon believes this, and simply does as he likes.

G.

No. XXXII.—MID-DISTRICT.

(1) Yes, my experience proves they might be far more largely adopted, but runners could be improved. Leaf is not materially injured.

(2) Many roads on easy gradients could be widened into tracks for single bullock carts.

(3) Only on large properties or groups of estates where roads had been laid out suitably.

(4) Clean weeding is cheapest and therefore best from every point of view.

(5) No.

(6) No, not in tea. Except when lay of land is unusually easy.

(7) Hedges of tea above roads and drains are tried now in parts of Dumbala. Cuscus suffers from a fungus at roots very often, also from scale and black bug and is not desirable.

(8) Machine pruners and pluckers. A light, cheap, narrow transport cart à la bicycle. *Better tempered steel tools!*

(9) Unquestionably, give gardens to all coolies who will use them and keep them clean; encourage growing vegetables largely.

(10) It would be a good thing for estates to have their own bazaars and canteens, but whether practicable is another question.

(11) Yes, liquorshops are a nuisance, but no use to abolish them. Their number might be reduced with advantage. Gothenberg System should be tried.

(Signed) T. KOKO.

NO. XXXIII.—HIGH DISTRICT.

- (1) Yes. No, not more than leaf carried in sacks.
- (2) On large estates only.
- (3) Yes.
- (4) Moss very bad for tea bushes.
- (5) No.
- (6) Fairly so. Only by terracing.
- (7) Treating them justly and getting a good day's work from them. Gardens generally given.
- (8) No. The nearer the bazaar, the bigger the debt.
- (9) No.

NO. XXXIV.—HIGH DISTRICT.

- (1) Have had experience of wire shoots. They might be more freely used; but by any method I have seen of working they damage leaf.
- (2) More cart-roads wanted. Less might be spent on useless tanks and a little more on cart-roads.
- (3) Not only tramways, but a modification of switchbacks could be used on estates and elsewhere.
- (4) Weeding is overdone especially on steep land and wind-blown ridges. The soil, if bare, cannot fail to suffer during the monsoon.
- (5) I would advise selected weeding; especially on steep land and exposed ridges.
- (6) Have no experience.
- (7) I consider the present system as satisfactory as practicable; but if a grass could be got that did not spread, much benefit would result from planting as suggested.
- (8) All estates of 100 acres or over, ought to be assisted to afford cart communication to the station at least from the boundary.
- (9) I think, coolies are generally very liberally provided with gardens so far as the estate is concerned. The cultivation and turning them to account is in their own hands.
- (10) Wherever there are coolies, boutiques or bazaars very soon follow.
- (11) Liquor shops are a curse to the coolies and a perfect nuisance to all concerned.

NO. XXXV.—MEDIUM DISTRICT

- (1) Wire shoots are very useful on steep estates for firewood, less so for leaf. Are already in general use where suitable. Do some damage to leaf if the shock at the base be too great. Runners are a great trouble and expense.
- (2) Wire tramways worked by power are being successfully worked and may often be much more economical than a cart road.
- (3) Transport of leaf by coolies does not take up much labour and 18' or 12' tramways would be of little use for this. For transporting tea, rice, &c., a wire tramway or cart road would be better. Few estates would suit tramways.
- (4) This was discussed in the papers about 1882-3 by "Ageratum" (G. D. Collinson) and others and has often been thought of since.

(5) Regular clean weeding is the cheapest and therefore most labour-saving method. No doubt soil would be preserved by letting weeds grow and "selected weeding" if it could be done would be good husbandry. Cleaning up after weeds have got in is very expensive.

(6) Have not tried, but think other forms of cultivation would pay better.

(7) Silt pits in the drains, about 4 ft. long by 1 ft. deep and the width of the drain have worked very satisfactorily. They must be kept cleared and should be at frequent intervals say 10 or 12 ft. apart.

(8) Labour would be saved if the migration of gangs could be diminished. The coolies in these migrating gangs won't work, but live on what the kangany can screw out of successive Superintendents.

(9) Certainly gardens are of great importance and when cultivated generally imply that the cooly intends to stay. Good lines, good water, and dispensaries on the estate or within easy reach, should be provided.

(10) If rice is issued on the estate, boutiques would be useful, otherwise coolies will go to the bazaar and exchange their rice for their other wants. More might certainly be done for the coolies, but they don't always know what is good for them.

(11) If you abolish the arrack tavern you encourage the illicit dealer who sells adulterated arrack, also the cheap gin shop. Few estates but have their regular supply of arrack on sale in the lines.

O. Y. A.

REVIEW OF LETTERS XXVII. TO XXXV.

The nine letters under review do not cover as much space, as the batches we had previously reviewed; but they are none the less suggestive on that account, nor are the opinions they contain less weighty or definite. While "Dumbuldanda Oya" has had no experience of wire shoots, and regards tramways a very doubtful ally, except in very exceptional places, "C. A." from a High District has used shoots for manure, firewood, grass, &c., and found them a great saving of labour. "E. W." from a Medium District commends shoots for leaf, as well firewood; but like "C. A." he has had no experience of tramways, and doubts whether they can be shown to pay on most estates. "Lowcountry," "G." from High District, and "T. Koko" from Mid District, endorse this commendation of shoots, express their belief in the saving of labour they would effect in many estates on which they have not yet been erected, and see no reason why leaf should be damaged, if the shoots are properly erected and carefully worked. All three correspondents are further agreed that tramways are unsuited to the average estate, and two of them prefer wider roads and light single-bullock carts as means of transport. The suggestions that circular saws for cutting firewood and packers for packing tea, should be more largely employed as labour-saving appliances are deserving of attention. "S." from High District, as also "M.," and "O. Y. A." from Medium District agree on the advantages of shoots; but, while "S." declares that leaf is not damaged by their use to a greater extent than leaf carried in sacks, "M." has found leaf damaged by every method tried. "O. Y. A." on the other hand, refers damage to too great a shock at the base—a drawback, surely, which can be avoided; while he has found runners a great trouble and expense. His experience of wire tramways is greatly in their favour, and they may often be much more economical than cart roads; while both are to be preferred to ground tramways which would not answer on most estates. "M."

is more venturesome than most of his contemporaries; for he goes beyond tramways, and suggests a modification of switchbacks, though he does not disclaim cart roads, and thinks more might be spent on them than on useless tanks.

As in previous letters, so in those now before us, there is much diversity of opinion on Weeding. "C. A." has often thought weeding overdone; but as a rule hilly lands would suffer from any other kind of weeding; and though selected weeding might be tried he deprecates less frequent weeding. "E. W." would prefer selected weeding to thoroughly clean weeding; but doubts if coolies could be got to carry out the selection properly. "M" is more unequivocal in his opinion that weeding is overdone, especially on steep land and wind-blown ridges, as a bare surface cannot fail to suffer during the monsoon. He therefore favours selected weeding. Not so "O. Y. A." who thinks regular clean weeding the cheapest and therefore the most labour-saving, though selected weeding would be better husbandry. "Lowcountry" (with the qualification that there is too much scraping), "G," "T. Koko" and "Dimbulanda," all favour clean weeding as the best and most economical; while the last-mentioned pleads the further advantage, that coolies are generally more contented on a clean estate, evidently sharing master's opinion, that weeds are pernicious wherever they are met! None of our correspondents have had experience of digging in any other growth planted between the tea, and most of them are averse to any experiment in that direction.

On Drainage there is less difference of opinion—some of our correspondents being content with their drains, others suggesting minor modifications, such as the growth of a grass that would not spread and silt pits in the drains at intervals. "C. A." however, condemns the present system of drainage, but cannot suggest a better at a reasonable cost. The objection against cuscus, that it develops a fungus in the roots, deserves investigation. We have not heard of it before, and it may be due to purely local causes. Hedges of tea above roads—and why not above drains?—are said to be popular in parts of Dimbula as a preventive of wash. The importance of gardens in conciliating coolies is generally admitted. Goats and cows are suggested as an auxiliary by one planter,—so that we may develop by-and-bye, to the proverbial "three acres and a cow"; another, a present once in 6 months of a Spinning and Weaving Company's cloth for good pluckers, and a present once a year for all; while from more than one comes the caution, that the cooly need be only treated justly, and a good day's work got out of him. That is, however, the special difficulty of the time, as "G." suggests. In his view, the cooly now does no more than half the work he did eighteen years ago and even in the plucking of leaf there has been a falling off within the past 8 years; and he refers it all to too frequent cases in Court and the ultimate decision against the Master. Yet, "Lowcountry" has had his coolies and kangannies for 12 years without trouble! The opinions on Bazaars and Taverns are of the familiar description, and present no special features calling for comment.

(Letters Continued.)

No. XXXVI.—LOWCOUNTRY.

(1) I have erected many wire shoots and firmly believe in them for all transport purposes where their gradient admits of a reasonable delivery *i.e.*

where not too steep—1 in 6 from point to point is a good all-round gradient though I have erected shoots as flat as 1 in 15. These, however, require runners of larger diameter to do good work, leaf is not damaged if properly packed, that is the loads should not exceed say 56 lb. It depends, of course, largely on the gradient of the shoot how many lb. one can send down without jamming at the end.

(2) No, I know of none (save wire shoots) of any importance.

(3) No, I suppose, I am one of the few planters who have had practical experience of tramways as I have had laid three miles of 2 feet gauge. No doubt circumstances exist, with reference to situation, &c., &c., where their adoption might with safety be recommended, but in the "vast" majority of cases, there is nothing to touch the cart road and bullock bandy for economy and serviceableness, and the native thoroughly understands this means of transport.

(4) No doubt of it. The trouble is that, in every case, you must find out what weeds, in your particular locality, may be left with advantage and what must be eradicated and educate your labor accordingly. The Indian system of leaving everything and holing in will never do for this country, but I could fill a page or two of foolscap on this subject!

(5) I don't believe in too long an allowance of moss—it tends to "sour" the soil.

(6) For five years, on Labukelle estate, I cultivated a creeping grass which was the most admirable prevention of wash as well as doing no harm to the tea I have ever seen. I eradicated all other weeds and let this grass spread. It died down and lay upon the ground like hay in the dry weather and grew again in the wet. It is common in Ramboda and Nawara Eliya especially on Olyphant. I don't know what has become of the experiment since I left the estate in 1892. Probably treated like many another idea as "a' rot" by my successor!

(7) Yes this is good and I have seen it adopted advantageously though I have never tried it myself. I have, however, used "guinea grass" for the same purpose, because it killed two birds with one stone and afforded cattle and horse feed as well as stayed wash.

(8) Factories are not yet so well arranged as they might be; tea too often in course of manufacture being carried "back" from machine to machine, instead of coming in at one end of the building "leaf" and leaving at the other "Tea." Where water power is abundant, we want firing by "electricity" to save fuel. This can and "ought" to be done. Dear fuel and continued squeeze in prices will no doubt bring it about.

(9) Coolies' needs and wants have grown since tea came in, but their pay has remained stationary. I am strongly of opinion that we ought to pay them more, and the heavy Coast Advances all over the country, (the greater proportion of which will be lost) simply mean that the cooly has obtained, in this form what would have done more good in the shape of "less advances and better wages." Sit on coast advances and pay coolies monthly should be the motto and at better rates.

(10) No, nothing of the kind, you can't drive labor in this direction. Coolies will go where they can meet the biggest crowd on Sundays, and have a yarn, and though you put Caddies just outside their lines they will sooner walk miles to get to the centre where the crowd congregates.

(11) No, I don't object to Ramasamy having a drink and it is better to know where the liquor shops, at which he drinks, are and that they are duly licensed. What is needed, however, is that some steps should be taken to see that only good liquor is dispensed and not, as is too often the case, a vile decoction, ruinous to the health of those who drink it, instead of sound arrack.

A. F. C.

No. XXXVII.—HIGH DISTRICT.

1. No actual experience except for firewood, but propose, having an overhead-wine-tramway for transport leaf from several estates to factory, and believe this is just the kind of thing required to economise cost and labour, especially where labour is most required.

2. I know of nothing special for this.

3. Have not gone into the cost of this, and much would depend on cost and lay of land, etc.

4. Only where manooties and scrapers are used and when not done by hands.

5. No. Certainly not; grevillas, etc. Trees should be planted on road sides and on shnek hills, etc., the falling leaves would do good and the timber be useful.

6. No. But heard of "Scotch thistle" having been tried on one of these estates, years ago, and saw a few here and there for a time, but they have long since disappeared. It was supposed they would have kept down the weeds and taken their place. I fail to see much advantage even though this had been successful.

7. Close draining when thoroughly done and rocks all cleared out and leading drains and roads, etc., fitted to meet all this, is quite sufficient to stop all wash I have found, but it must be *done well* and not half finished.

8. ———

9. Let them have gardens of limited extent; they like them, but this does not positively keep them to the estate.

10. No. I would not multiply bazaars, but prefer a regular market for all, not far off, but certainly not too near. My objection to bazaars too near is—the amount of stealing in firewood, grass or anything the coolies can lay their hands on—that goes on when this is the case. Also if large properties, there might be with advantage estate dispensaries.

11. We have one not far off and I totally disbelieve in allowing one; it is only a cause of general evil, gambling, drunkardness, etc., and it is, I consider, absolutely unnecessary.

W. B. J.

No. XXXVIII.—MEDIUM DISTRICT.

(1) Shoots save a lot of labour, and in many cases some pay themselves. Might be much more used. Don't think they damage leaf worth speaking of.

(2) None that I know of.

(3) Can't say; but coolies' wages are low, and engineers' are high, and a tramway would cost a lot. It would all depend on the outlay required, as to whether profitable or otherwise; a big Company should try.

(4) No.

(5) No. At least on old estates. Tried it once, and that was enough. Leaf returns fell off, and the saving in weeding was gone before you could wink.

(6) Never tried but would strongly advise another fellow to try.

(7) Present system of draining works well enough; as the best of the soil is soluble, trapping would leave the silt which is not much worth. Mud taken from a dam, is an admirable top dressing, did well for coffee; does well for tea.

(8) Strict supervision, and every cooly doing his full share of work would help a number of estates. It is a bother, and worry to see to this, but it pays well.

(9) Giving perquisites spoils the cooly, it is like setting a beggar on horse-back. Kind, firm, treatment, readiness to *re* consider decisions, keeping in touch with your force, and a joke thrown in now and again go a long way to cause content.

(10) More boutiques mean more Moormen, and where there is saleable produce, the close proximity of such gentry is to be avoided. If the estate ran its own botique it might be difficult, but tea planters have enough to look after already.

(11) I suffer from liquor shops licensed and unlicensed, with rascally toddy-sellers to boot, results

gambling, stealing, lawlessness; had a set of lines burnt down by a drunken rascal; and thieving; would vote for the abolishment of liquor shops, or their reduction, and a tax on toddy trees, anything to save my labour force from the temptation to drink, and the evil results which follow.

HANTANA.

No. XXXIX.—HIGH DISTRICT.

(1) Certainly saves labour on long estates, and does not damage leaf if rightly managed at the receiving end.

(2) ———

(3) Don't think tramways would be cheaper than cooly transport.

(4) Estates of country must be kept clean; for if allowed to grow, the blocking of weeds on our hilly land would cause more loss of soil than ever.

(5) Selected weeding would be a good experiment.

(6) Have been recommended to try a crop of clover, but abstained, as digging it in would also loosen the soil.

(7) Rows of cuscus grass would be good on steep land. On gentle slopes the litter from grevillea trees is a grand prevention of wash.

(8) ———

(9) Anything by which a coolie can make money renders him more willing to settle on an estate, therefore a garden and a cow, though bothersome, are to be recommended.

(10) A coolie will go to his favourite boutique, whether near or far away, and prefers a village, where he can gossip and amuse himself.

(11) Drinking is very largely on the increase; but the idea is always held that if public liquor shops were abolished, private and illegal ones would supply an equivalent quantity.

A. V. R.

No. XL.—SOUTHERN DISTRICT.

(1) To a certain extent the leaf is damaged. Unless there was *great* saving of labour, I should prefer not to shoot leaf.

(2) ———

(3) No, I do not think so. In *exceptional* instances this might be done.

(4) Yes.

(5) I should advise hand weeding only, on ordinarily clean estates. It is "canandy" weeding and *scraping* which ruin. *Mosses* to a certain extent *are* left, but not ferns &c.

(6) I should prefer to see results before saying.

(7) Yes, I think not. The cuscus grass would be the only thing benefitted by the surface wash. It would not prevent the soil at the tea roots being washed down to the next drain.

(8) Thoroughly good *supervision* perhaps saves more labour than any method one can devise off-hand.

(9) Most have gardens who care to. Good warm lines and comfortable. Inducements in cash picking over and above task for the day. A wholesome regard and confidence in their Durai.

(10) One or two bazaars on the estate are a great institution if properly worked even by the Superintendent and each cooly's account kept regularly and explained monthly and signed by him. It is the Chetties and Moormen who ruin labour, and unsettle them. It is they who compel coolies in many instances to ask a "tundu," or fraudulently obtain their advances to procure coolies from the Coast.

(11) No liquor shop on either of my places, but villages are too close, which is as bad as any liquor shop. I am afraid if liquor shops were abolished the coolies would migrate to where they *could* indulge in drink *i. e.* villages &c., &c.

S.

No. XLI.—KANDY DISTRICT.

(1) Have used wire sheet for the last 5 years in sending down leaf to factory, little or no damage to leaf, provided you have a good buffer of grass to wet the bag.

(2) ———

(3) Would probably be too expensive, much cheaper to have cart roads wide enough for single bullock carts.

- (4) No, as regards coffee.
 (5) No, you would never get coolies to discriminate between the different weeds.
 (6) No.
 (7) Fairly so, would have more water-holes cut.
 (8) ———
 (9) Yes, here coolies have their garden but few take the trouble to cultivate them.
 (10) No, certainly not.
 (11) No, no I think the amount of drunkenness amongst coolies greatly exaggerated. T.C.H.

**“THE GREVILLEA ROBUSTA” IN THE
 PLANTING DISTRICTS OF CEYLON:
 BIG TREES; AND WHAT THE LITTER
 OF LEAVES MIGHT HAVE DONE
 FOR COFFEE?**

A planting correspondent writes:—

“Re your editorial note about size of *Grevillea* trees, there are six very old trees near my bungalow. Mr. ——— told me they were large trees when he came to the district, 26 years ago. I measured the circumference of them yesterday and find the largest stretches the tape at 6ft. 2in., a foot above the ground.”

Well, done we say! The size given is not far from the maximum size quoted of 8 feet in circumference. The trees referred to are on a well-known Kotmale estate, and cannot be over 34 years old (if so much) because as “Senex” showed the other day, no plants were issued from Peradeniya Gardens before 1862 or 1863.

In this connection, it is of interest, while noting the general testimony to the value of the “*grevillea*” planted in tea fields, to ask whether, if it had been generally adopted as a shade tree in the coffee era, its presence and beneficial influence would have delayed, or prevented, the ruin of our old staple? One proprietary planter writing from a high district expresses his opinion on this point as follows:—

“I know by practical experience that the good done by *grevilleas* is great. Every acre of tea on our ——— places (naming an old coffee district) has been planted with them, and I am planting up this estate as fast as I can. I think there are many acres of coffee that have been cut out and planted with tea, which, had we known the value of *grevilleas*, would still be bearing paying crops of the old staple.”

Has this been tested at all on any of few coffee fields still remaining to us? Or is it too late, even now to make an experiment? What does “Senex,” as an old coffee planter, say to the use of *grevilleas* among coffee?

THE NYASSALAND COFFEE COMPANY, LD.

A general meeting of the Nyassaland Coffee Company, Limited, was held on the 25th Sept. at the Registered Office of the Company in Baillie Street. Mr. G. K. Deaker presided and the others present were Messrs. F. Macindoe, W. Shakespeare, J. H. Carson, R. D. Carson and H. Creasy. Mr. Jameson was represented by his attorney Mr. Macindoe. The following report was adopted:—

Superintendence.—Since last year’s report was presented to the Shareholders, the Directors regret to report that Mr. G. M. Crabbe had to resign his position owing to ill-health, Mr. L. T. Moggridge was appointed in his place, and with Mr. S. Robins looks after the Company’s interests in Nyassaland.

Progress of Work.—During the financial year which closed in Nyassaland on the 31st March, 1897, 240

acres were opened and planted, making a total planted acreage of 250 acres.

Owing to the failure of a large nursery which was destroyed by grub, the expenditure on plants has been more than anticipated. A small consignment of seed from Brazil also proved a complete failure, none of it having germinated.

Estimate for season 1897-98.—The Superintendent has estimated for a further 250 acres to be opened and planted this year, but the Directors hope that he will be able to manage at least 500 acres, and have advised him accordingly. Labour is reported to be plentiful, and the only difficulty is the securing of an adequate supply of plants. Should additional European supervision be required, the Directors have authorized the Superintendent to engage that on the spot. The health of the Superintendent and Assistant Superintendent, the Directors are glad to report, is fairly good.

Purchase of Land.—During the year the title for the 2,000-acre block arrived, and the purchase was carried through. The Company now owns 3,476 acres in all, which was the acreage stated in the Prospectus to be purchased.

The negotiations for the acquisition of an adjoining estate in partial bearing referred to in Directors’ previous report fell through, and the money in hand will be devoted solely to the development of the already purchased land.

Mr J. H. Carson retires by lot from the board of Directors, but is eligible for re-election. It will be necessary to appoint an auditor for the ensuing year.
 CARSON & Co., Agents and Secretaries.

PLANTING NOTES.

ROYAL GARDENS, KEW.—Bulletin of Miscellaneous Information. Contents for February and March, 1897:—A Lily Bulb Disease; Tengah Bark; West India Sugar Trade; Prices of Home-grown Timber for 1896; Myrrh; Botanical Exploration in Yunnan; Kino from Myristica malabrica; Cultivation of Cotton in Egypt; Papain; Miscellaneous Notes.

THE NYASSALAND COFFEE COY’S Directors have not a very bright account to render of their stewardship so far; but they have not atated one jot of their faith in the enterprise and hope to have 500 acres added in the current year to the 250-acres already planted with coffee. Well one.—that area should give a fair trial to the capabilities of *B. C. Africa*.

EXPEDITION TO TORRES STRAITS AND OCEANA.—At the sitting at Toronto of the Anthropological Section of the British Association (for which he is Secretary) Professor Haddon—according to the *London Times*—presented a report “on the necessity of the immediate investigation of the anthropology of oceanic islands.” Next Spring Professor Haddon is to renew his acquaintance with Torres Straits and South Pacific isles in order to finish his investigations there. The Council of Cambridge University have made him a grant of £300 for this Expedition and while he will be in command he will have five or six assistants. From a correspondent’s letter on the subject we quote as follows:—

Mr. Ray, the greatest living expert on the languages of the Pacific, will study the languages. Two young Cambridge honours men (medical)—very clever and extremely cultured—will more particularly study the physiology of the senses and experimental psychology. This class of work has never been done on savages and will be quite a new line of research. Another man is an under-graduate, a History student, and a first-class photographer who has published a book “Through Egypt With a Camera.” The two medicos are rich and pay their own passage money there and back, (100 guineas each); and another £400 is needed which will have to be raised before the party starts. Savages are fast disappearing and the work must be done at once.

CEYLON VS. JAVA :

COFFEE CULTURE IN EAST JAVA BY
CEYLON PLANTERS.
COFFEE IN QUEENSLAND.

There is really no comparison between the extent, population and natural resources of Java—one of the richest islands in the world—and Ceylon with its comparatively poor soil and scant population. Nevertheless, for political reasons, the British Government was glad to exchange Java for Ceylon with the Dutch at the peace of 1815. It was rightly felt that the geographical position of this island made it indispensable to the Power holding India.

At the last Census in 1891, the Western Province of Ceylon was found to be occupied at the rate of 532 persons to the square mile; but at the other end of the scale, we had only 19 to the mile in the North-Central Province. Even in the Western Province there is still a considerable area of unoccupied land, under forest or low jungle. But if the whole island were occupied at the same ratio as this province, Ceylon would have in its area of 25,333 square miles, a population of 13½ millions—which is probably, over rather than under the maximum population reached in the palmiest days of native rule from Anuradhapura.

Let us now turn to Java, and we find from the *Statesman's Year-book* that, while the Dutch claim to hold in their Netherlands Indies (including large divisions of New Guinea and Borneo) no less than 736,400 square miles of territory with a population of 33 millions, the gem of their "Indies" is undoubtedly in "Java and Madura" covering 50,554 square miles with a population of over 25 millions. Java, therefore, with double the area of Ceylon, has more than eight times our population! Of Europeans, Java has four times as many as Ceylon. Indeed, Java on the average is as thickly populated as the South-western division of this island, while its soil is far superior and its means of communication are not one whit behind. At the end of 1894, Java had over 1,000 English miles of railway open, and by this time has probably four to five times the mileage existing in Ceylon. It is no wonder, therefore, that British capitalists have been attracted to Java, and more especially, that Ceylon planters partly because shut out here from further investments through the embargo laid on Crown lands, but more especially in order to try coffee, rather than tea, in a new division of a country with virgin soil—should have found their way to Java.

Our attention has been called to the subject through information which has reached us, respecting the success of the coffee enterprise already undertaken by several well-known Ceylon proprietors in East Java. Messrs. D. and J. R. Fairweather, in association with Mr. J. H. Starey, took up a block of 4,000 acres in that quarter, of which altogether 1,300 acres have now been opened as Glen Nevis estate with "Arabian coffee" in successive clearings which range from one, two, three to four years old, the largest (about 500 acres) being in its third year. That the venture is proving a success may be judged from the fact that the crop gathered this year aggregated 6,000 cwt. The labour supply is described as ample, though the rate of pay—the standard being a gold one in Java—is not quite so cheap as in Ceylon. But the Javanese and Madurese

employed are of a manly type and do good work. Not far off is the block taken up by Messrs. Rutherford, Todd and Talbot—some 2,000 acres, of which 300 to 400 acres have been planted, the oldest coffee being over two years. Whether Messrs. Wellton and Duns-mure are to invest in the same division, as the result of a recent visit, is not known to us at present. Elsewhere in "old Java," if we may so call it, Mr. A. E. Wright and a relative have taken up an existing estate and are well pleased with their tea as well as Liberian coffee and cinchona. Everywhere there is the same rich volcanic soil; and while the last-named gentlemen are in the midst of the well-occupied planting districts commanding road and rail, the locomotive line constructed through the heart of the island had, at last report, got within a few miles of that part of East Java where Glen Nevis and its sister estates are situated.

So far, we have been writing on what may seem partial information, although the figures given are beyond dispute; but we are in a position to add the opinion of a competent and disinterested observer by quoting a letter from Mr. Donald Mackay to Mr. D. Fairweather, which has been courteously placed at our disposal (to be followed, we trust, by another after Mr. Mackay has actually gone over Glen Nevis plantation). Meantime, here is what he writes:—

Soerabaya, Java, Sept. 7.

"I arrived here on the 6th yesterday, Mr. Schiff met me and has shown me every kindness. I find however that the direct overland route to the Glens involves a very rough walk over the mountains and disabled, as I partially am, from a severe attack of lumbago, I cannot face that part of the journey and must wait departure of local steamer on 13th for Banjoe wangi. This will of course involve a much longer stay in the island than I anticipated, but as I came to see the Glens I am unwilling to leave the principal part of my journey unaccomplished. I expect to be back in Batavia early next month. I have been through the curing mill here and find it crowded with "Glen Nevis" which has produced a fine bold parchment superior to anything else in the place. Reckoning roughly and mentally what you have had this season, I make out something like 10 cwt. per acre which is simply enormous for coffee of four and three years old and speaks volumes for the soil and climate. It is possible the trees may have overdone themselves this year in giving this wonderful crop which I believe excels anything known before in the island. I shall be interested in seeing the condition of the trees after bearing such a heavy crop. It is unfortunate I am so late, as crop is all over and I shall be seeing the trees at their worst."

We do not expect that Mr. Mackay will find much the matter with Glen Nevis trees even after bearing so heavy a crop, considering the depth and richness of the soil. So far, we understand, the Dutch authorities have been very considerate, if not liberal, towards the British capitalists. It is their desire that the enterprise by "foreigners" in their territory should, if possible, be located in the one extensive and hitherto unoccupied district; and from all we learn, we should be inclined to pin our faith more to this coffee investment in East Java than to the Dnumont Company venture in Brazil.

Mr. J. R. Fairweather, who has been suffering from fever, left Colombo by the Orient steamer for a trip to New Zealand, returning *via* Queensland and Torres Straits to Java, where his brother and partner,

Mr. D. Fairweather—at present managing Yaterapia—expects to meet him before the end of the year. If there were time we should recommend to Mr. J. R. Fairweather a visit to the coffee gardens in the Cairns district of Queensland, where soil and climate seem specially favourable to our old staple; while the great difficulty, labour, might be overcome if (as Mr. Wardlaw Thompson reported) the Kanakas in the Pacific Isles, are now very glad to take employment from responsible planters in Queensland. At Cairns, which is in 17 degrees South latitude on the North-East coast of Queensland, there is a railway 42 miles long up to Herberton; but after 6 miles on the flat, in twelve miles of this line an elevation of 1,600 feet is attained through very grand scenery, rendered more impressive by the back-ground of the "Great Barrier Reefs" in the Coral Sea of the Pacific Ocean. Then there are 25 miles across a plateau with good soil. It is doubtless alongside this railway that coffee has been cultivated so successfully, although as yet only to a limited extent. For a capitalist doing business on a big scale, there is probably no comparison between the advantages of investment in East Java with plenty of rich land and good labour and in Northern Queensland with no local labour. But then, in the latter case there is the consideration of being under British rule.

BOTANICAL NOTES FROM MINCING LANE.

A botanical observer who visited the Mincing Lane showrooms lately gives us some notes of what he saw from his point of view. The goods which cover the tables he writes, bring before our mind within a few yards the three divisions of the vegetable kingdom mixed together, not by any means in accordance with the view of a botanical systematist in the dicotyledonous group we spot kola nuts, the true seeds of *Cola acuminata*, which about twelve years ago were to be had only from their native country, tropical Africa. About the time of the Colonial and Indian Exhibition, in 1886, when some fine fresh samples were shown from Jamaica and other West Indian islands, the cultivation of the plant was strongly recommended by some, and ridiculed by others—the wisdom of the former has since been shown. Coca-leaves, again, the produce of *Erythroxylon Coca*, are a comparatively new product which has thoroughly established itself, and which is a near botanical ally to the kola though belonging to another natural order, *Linaceæ*. Further on we see a sample of guarana, a peculiar substance from Brazil, made by beating up the small seeds of *Paulinia sorbilis*, a close ally to the horse-chestnut, into a pasty mass and then rolling it into thick sticks and drying it. The invigorating power of this substance has been known to the natives of Brazil for a very long period, and even at the present time they use guarana as of old, in the preparation of a beverage by grating a small portion of one of the hard cakes or rolls into a cup of water and drinking the contents. For this purpose they carry a roll of the guarana, and the rough tongue of a fish to grate it upon with them on their journeys. Its introduction into English commerce, like that of kola, is of comparatively recent date. Proceeding from the *Sapindaceæ*, to which guarana belongs, the produce of a leguminous plant next catches the eye—namely the hair from the pods of *Mucuna pruriens*, popularly known as cowhage, and in commerce as cowage or cowhage.—C. & D.

It may not be out of place to mention a sample of Boldo-leaves (*Peumus boldus*) a Chilean shrub, which was introduced to this country in 1874 as an aid to digestion, and as a remedy in liver diseases. The discovery of the properties of the plant is said to have been made by noticing the beneficial effects on a flock of sheep that were suffering from liver

disease. The fold in which they were enclosed have been repaired with two boldo twigs, the sheep ate the leaves and shoots with the result that they rapidly recovered. Some singular-looking dried and shrivelled flowers have also been shown under the name of "Cactus flowers." Though they cannot yet be satisfactorily identified, they probably belong to the genus *Lhipsalis*, a group of fleshy jointed-branched leafless plants belonging to the *Cactaceæ*. They are of but little use economically, though in Brazil the fruits of *Lhipsalis pachyptera* are reputed to have antiscorbutic and antibilious properties, and in the West Indies *Lhipsalis Cassytha* is used as a vermifuge.—*Chemist and Druggist*, Sept. 4.

"QUEENSLAND AGRICULTURAL JOURNAL."

THIS is the title of a new agricultural publication, only two numbers of which—those for July and August—have yet been issued. The journal is published by direction of the Minister for Agriculture in place of the bulletins that were issued from time to time. "Essentially of a utilitarian character"—to quote from the journal itself—"The Queensland Agricultural Journal will be devoted mainly to the publication and wide dissemination of articles of a popular educatory character. It is not intended that it shall take the place of an Agricultural Newspaper, nor that it shall in any way interfere with the peculiar work of such journals." The bulletins that used to be issued by the Department of Agriculture, Queensland have always been of a most useful and practical character, but the journal now issued while including all the subject matter of the bulletins contains special contributions of much merit, and the letter-press and illustrations help to make it an agricultural publication of a high order. Indeed this new journal and the New South Wales Agricultural Gazette are undoubtedly among the best managed agricultural publications to be met with anywhere.

PLANTING IN PAHANG, STRAITS SETTLEMENTS.

(From the *Administrator's Annual Report*.)

Of planting, other than rice and the usual native fields of maize and sugar-cane, there has been little. The Liang Syndicate has brought 130 acres of land under cultivation, and has planted it with coffee during the year. A further plantation of 120 acres will be opened up on the same property during the current year. The coffee already planted is reported to be doing very well, and the land selected is said to be exceptionally good. It is to be hoped that this is but the beginning of an enterprise, which, if successful, may greatly benefit this State. It is probable that the superior rainfall on the east coast of the Peninsula will prove to be to the advantage of the coffee planter, but those who open up land in Pahang have still to contend with great difficulty as regards transport. The labour employed on this coffee estate is drawn entirely from Java and Sumatra.

Rumi planted on the property of the Liang Syndicate has been favourably reported upon, and it is possible that decorticators will be erected during the current year.

Rumi grows well on Pahang soil, but the necessity for its immediate decortication renders it improbable that it will be widely grown for some years to come.

ALOE FIBRE.—On page 306 we quote an extract in which a hopeful account is given of the trade in aloe fibre. There seems to have been a continuous demand for the fibre from all parts of the world and the prospects are such as to warrant the statement that the trade affords a profitable field for investment.

MR. NAFTEL'S REPORT ON DOMINICA.

We have received both from the Ceylon Secretariat (and from Mr. Nafel direct) copies of the "Report of Mr. C. O. Nafel on the Forest Lands and Estates and Agricultural Capabilities of Dominica," sent to us at the request of Mr. Templer, the Administrator of Dominica. The Report was printed after Mr. Nafel left Dominica, so that he had not the chance of seeing it through the press, which accounts for certain aberrations in paragraphing. The Report itself is dealt with rather fully in certain of its aspects, by our London Correspondent on another page; but we may supplement what is there said. To the letterpress is prefixed a topographical map on which are indicated the several divisions with their elevation from 500 to 3,000 ft. above sea level and the rainfall (from 67 to 196 inches) for which there are detailed tables in an appendix. Mr. Nafel's paper is laid out after a very elaborate and satisfactory fashion, beginning with "a general description of the island" (Dominica is shaped like a cacao pod) 29 by 9 miles greatest length and width, the total area being 190,600 acres—or about the total extent of the section of Ceylon between Nawalapitiya, Adam's Peak, the Bopatalawa Plains, Horton Plains and Nuwara Eliya—but the highest peak in the West Indian island is only 4,747 feet. Roads are few and generally bad. Climate, temperature and rainfall are well reported of. So is health and soil—the latter being of volcanic origin and rich. The census of 1891 showed a total of 26,841 persons of whom 335 were white, 6,806 coloured, and 19,700 black. The females exceeded the males by 2,723. The "blacks" go to work freely on estates—9d to 1s a day for men and 6d to 8d for women—task work preferred. Here is a typical extract:—

I think I have now shown that, with its rich soil, good climate and command of labour, Dominica fulfils all the conditions required for the profitable cultivation of most tropical products. What these are I will show later on in this report but I propose first to give some attention to Arabian coffee, as it was at one time the principal export, and right, I believe, have continued to hold that position but that the high price of sugar led not only to the abandonment of the cultivation but to the actual rooting out of the trees. It is the generally received opinion that the abandonment of coffee cultivation here was due to the ravages of a blight; but, that this must be an exaggerated or erroneous idea, is shown by the fact that coffee trees are now found growing in the bush on portions of estates which have not been cultivated for 50 years or more, and that, when relieved of the jungle growth, the old tools throw up strong suckers which crop well as soon as they reach the bearing age. These remnants of the old cultivation are found in almost every district in the Island and such vitality in so delicate a plant as Arabian coffee proves both the fertility of the soil and the suitability of the climate for its growth. The nearest approach to systematic cultivation of coffee that saw was on Dr. W. Rees Williams's estates Bona Vista and Emclia. These are situated about five miles from Roseau on the Leeward coast at an elevation of between 1,000 to 2,000 ft. above sea level. He has some of the very old coffee there, of which I have spoken, both of the Arabian and Mocha varieties and the very fair crops these old trees gave him led to his planting more. The land is said to have all been coffee in the old days and is generally very steep and rocky. Its rocky nature has preserved much of the soil and much of it has reverted to forest or at any rate heavy bush. It has been opened in three or four small pieces, the largest of which does not, I think, exceed three acres. The oldest is about five years, and the youngest under two years old. Individual trees and small bits in the various fields are

good, but other patches, and generally these predominate, are thin and weedy. Some of the trees are evidently wind-blown and it is noticeable that all the trees that are fairly sheltered are doing well. The fields have not been filled up with "provisians" as it is usually done here but some bananas have been put in for shade and there are a great many weeds. The most attention that they have ever received is, I understand, five weedings a year.

Of Liberian coffee, Mr. Nafel makes a good report:—

This variety was introduced into the Island during the "seventies" by the late Dr. Imray and a few trees were planted on his small experimental garden St. Aroment. They are now about 20 years old and are still bearing well though they have not been cared for as well as they would have been if there had been a large acreage under the cultivation. The Planters have only recently begun to give much attention to this coffee, many having kept to their old staple, sugar, in the hope that prosperity would return to it. Others, more enterprising, have taken to lime growing which in its early days gave very large profits and still pays well, though the price during the last few years has fallen. There is consequently as yet no extent of land under Liberian coffee, but it is now being seen that it will pay to grow and, I believe, the next year or so will show a good increase in the acreage. There is hardly a place in the Island where it will not thrive and there are large tracts of virgin forest where it will flourish as well as anywhere in the world. The elevation best suited for Liberian Coffee here will be found to be from sea level up to 1,500 ft. but I am not prepared to say that it will not do well even higher than this. There is, however, no necessity to go into lands higher than 1,500 ft. for there are thousands of acres in the Island below this, the best being in the Northern district on the Lower Slopes of Morne Diablotin.

We need not refer to what Mr. Nafel says about "Possible Enemies of Coffee," or on the "proper cultivation of coffee"; and we must postpone our notice of tea, coconuts (nuts sell for only 3s per 100 lb), nutmegs, other spices, cardamoms, tobacco and limes (a profitable industry for lime juice). There is much under these headings to be quoted more specially for our *Tropical Agriculturist*. For the present we cannot do better than close with the summary which Mr. Nafel affords of the various planting districts, into which he divides the little island, with reference to further settlement, as follows:—

I.—Extensive flat—sheltered from prevailing winds—well watered—suited for Arabian coffee—2,500 to 3,000 ft.

II, III, IV.—Long valleys running into No. 1—suited for Liberian coffee, cocoa, kola, nutmegs, limes & oranges.—800 to 1,200 ft.

V.—Large plateau suited for same products as II, III, IV.—well watered and sheltered.—500 to 1,500 ft.

VI.—Slopes close under Morne Diablotin sheltered—suited for Arabian coffee.—2,000 to 3,000 ft.

VII.—Undulating slopes North of Basin Will—heavy forest—very good soil—parts possibly good for tobacco—excellent tea land—sheltered and well watered.—600 to 1,800 ft.

VIII.—Pagona Valley—well watered and sheltered—heavy timber—flat land—900 to 1,300 ft.

IX.—Layou Flat—large extent of flat land—well watered and sheltered—heavy timber.—800 to 1,000 ft.

X.—Very fine land—particularly suited for Arabian coffee—well timbered and sheltered.—2,000 to 3,000 ft.

XI.—Fine extent of undulating land at foot of Trois Pitons Range—sheltered and well suited for Arabian coffee.—1,800 to 2,800 ft.

XII.—Continuation of No. IX.—well watered with rich soil.—1,000 to 2,000 ft.

XIII.—Head of Roseau valley—very broken land but parts are suited for cocoa and Liberian coffee—1,000 to 1,500 ft.

XIV.—Soil very rich—suited for cocoa and Liberian coffee—sheltered.—800 to 1,500.

Though VII, VIII, IX, and XII, all contain rich soil and are generally sheltered, the absence of information about the rainfall makes it difficult to say for what cultivation, besides tea, they are best suited. The rainfall of these districts probably approximates to 200 inches annually.

COFFEE IN COSTA RICA.

It will be remembered that Mr. J. L. Shand went out to Costa Rica last year to inspect a coffee plantation and large extent of land in private hands. The result was the formation of the "Sarapiquí Estates Coy. Limited," of which Mr. Shand and Mr. Huntly Thring—as representing Ceylon—are directors. This mail brings us information (not from Mr. Shand) of the progress of the Company, which we quote as follows:—

"The first lot of coffee has come and has realized the very good price of 108s for the A mark with an average of 96s for the parcel. I send you a sample of the mark which I feel sure will interest you and friends in Ceylon, the size of bean will make some open their eyes. The colour is not up to the mark, owing to being prepared in a most primitive fashion; but by next picking matters in this respect will be put right. We are all so far quite content with the outlook and I trust the next year will enable the Company to take a place in the ranks of dividend-paying concerns. All the shares are taken up and I think it will not be easy to obtain any later on when more definite news of the coming crop is to hand."

BENEFITS OF THE NEW AMERICAN TEA LAW: CHARACTER OF THE MERCHANDISE IT HAS EXCLUDED.

The following letter from the Indian Tea Commissioner to a leading New York journal explains very fully the interview with Mr. Phelan (Chairman of the Committee of Tea Experts) which it answers. The headings of Mr. Phelan's interview may, however, be given:—

"No Tea unfit for use Admitted to this Country—The Law has been Rigidly Enforced in all four Ports of entry where Tea Examiners are Stationed—Estimated supplies of Tea this Season.—Also his estimate of tea supplies:—"

	Season—	
	1897-8.	1896-7.
Greens	14,000,000	16,216,906
Japans	40,000,000	42,626,418
Formosa	17,000,000	18,994,324
Amoy	200,000	1,152,848
Foochow	3,600,000	3,430,327
Ceylon	8,000,000	13,080,536
Congou and India	3,000,000	3,000,000
Total	85,800,000	98,501,359

Making deficit for the present season as
against last year of 12,701,359
Here then is Mr. Blechynden's reply:—

THE NEW TEA LAW IN AMERICA.

New York, Sept. 2, 1897.

Editor "The Journal of Commerce and Commercial Bulletin":

Sir,—I have read with some attention Mr. Phelan's remarks on the "Benefits of the New Tea Law," to which you give prominence in your issue of this morning, and I desire to take exception to certain matters of facts and figures, for which you make Mr. Phelan responsible. In the paragraph relating

to India and Ceylon teas you quote him as saying: "The importers of India and Ceylon teas made an appeal against the rejection of certain lots for excessive dust on the ground that some of the needle leaf was excluded as dust. By request of the General Board of Appraisers a conference was held between the tea examiner and the Committee of Standards, which resulted in an equitable adjustment of the matter, which arose simply through a misunderstanding of the term 'dust' as contra-distinguished from Pekoe tips and small leaf." The fact is that appeals have been made to the Board of General Appraisers, and those gentlemen, while admitting that the regulations under which the fine leaf teas from India and Ceylon are excluded are opposed to the spirit of the law, appear to consider that their powers are limited in the matter until the regulations are changed, and this can only be done by the Treasury Department in Washington. The committee of which Mr. Phelan is chairman, has not actually met since the "misunderstanding" or misuse of the word "dust" in the regulation in connection with India and Ceylon teas became apparent, and the "conference" between the "Committee of Standards" and the tea inspector, to which Mr. Phelan refers, could not, therefore, have a practical result so far as the question at issue is concerned, so long as the regulations remain unchanged. I, therefore, take exception to Mr. Phelan's statement that an equitable adjustment has resulted. Importers' protests are in abeyance, and the India and Ceylon teas under appeal are still being held over pending an "equitable adjustment."

The flaw in the regulation relating to "dust" is that it fails to lay down a rule by which the examiner shall distinguish "needle leaf." The 16 mesh sieve is admittedly inadequate for this purpose, and is yet the only definite guidance provided by the regulations. It is further admitted that India and Ceylon tea leaf separated by 26 mesh sieve, contains no particles which can be classed as dust in the sense used in the regulations.

I have stated that Mr. Phelan's figures are wrong, and this I will proceed to show. The figures quoted by Mr. Phelan are practically those published by Messrs. James and John R. Montgomery & Co. in their circulars, with some slight differences, to which I will refer. Messrs. Montgomery & Co.'s statistics, and therefore Mr. Phelan's figures, include the imports for Canada, as well as the United States, they expressly omit all indirect shipments, which in this connection means for England. The latter I propose to supply. The fact that the statistics are for all North America should be borne in mind when reading Mr. Phelan's contention that the new law, applicable to the United States alone, is the sole factor in reducing the supply of tea available for Canada as well as the United States. As Messrs. Montgomery's statistics omit indirect receipts of teas their figures for imports of Congou from China are deficient to the extent of the imports of this tea via London (I concern myself only with black teas). Mr. Phelan therefore adds to their figures the round amount of two million pounds for season 1896-7, but makes no allowance from this source for season 1897-8, actually reducing Messrs. Montgomery's figures for the estimated supply by one million pounds.

Curiously enough, Messrs. Montgomery & Co. omit the figures for India and Ceylon teas, but Mr. Phelan makes a statement that the imports for season 1896-7 were three million pounds, and estimates the supply for season 1897-8 at the same figure.

The actual imports of India and Ceylon tea during the year 1896 were 9,681,040 pounds, which is six and a half million pounds in excess of Mr. Phelan's figures. The estimated supply for season 1897-8 is greater than that of the previous year. The actual imports for the half year ending June 30, 1897, are 6,249,608 pounds, more than double Mr. Phelan's estimate of the supply for the entire season and about 66 per cent increase over last year's imports to same date.

The figures I use have been published by accepted authorities, and are open to all in the tea trade. If the law is strictly enforced it may be that much of the most impure tea from China and Japan will

be excluded from the United States. The deficiency can readily be met with supplies of the unquestionably pure teas from India and Ceylon. If an arbitrary regulation which acts in a manner never contemplated or sanctioned by the law is applied to these teas, and the finest are kept out by classing them as "dust," it will probably be a good thing for those who are importing Japan and China teas.—Yours, etc.,

RICHARD BLECHYNDEN

WYNAAD PLANTERS' ASSOCIATION.

AN EXPERT TO DEAL WITH COFFEE AS PROPOSED BY THE UNITED P.A., S. INDIA.

From Proceedings of a General Meeting on Sept. 1. The last subject requiring notice is the decision arrived at on the employment of experts. We all felt that Mr. Newport's scheme deserved support. The Government of Madras will pay half the expense and the Lorver Pulneys will raise R4,000 to R5,000 for this purpose. Green bug does not at present affect us, but as it has spread from Ceylon to the Lower Pulneys it may easily spread north as far as coffee extends. Personally we hope it requires a dry district to thrive in and our heavy monsoon will kill it, but that is no reason the U.P.A.S.I. should not afford help to districts that need it.

There was considerable disagreement as to the practical benefit likely to accrue from employing an expert for improving cultivation, and the subject was thoroughly thrashed out in special meetings of those most interested. Eventually it was agreed to meet the views of both sides by trying to secure the services of Mr. Cameron to improve the strain of coffee, and also to ascertain if sufficient support could be obtained from Associations and Governments interested to obtain with the help of the U.P.A. the services of an Agricultural Chemist.

MACHINE-MADE TEA IN AMERICA.

One cannot withhold admiration of the pluck, enterprise and persistency that characterize the work of the agents of the India and Ceylon tea syndicate. They came into the markets of America to stay. Encountering a prejudice, as unreasonable as inexcusable, they have, by patient endeavor, made rapid strides in its overthrow, and succeeded in making it obligatory upon every up-to-date distributor of tea to place Ceylon and India tea in stock. By judicious and well directed advertising they have created demand, and with all classes of the people. Think of the enterprise shown in securing the cover page of the *Ladies Home Journal*, which reaches 700,000 American homes, and to the unique and convincing ads. in other of the foremost journals and magazines of country, which enterprise is working directly for the benefit of the retail dealer. These teas not only have merit, but are much more economical than China or Japan growths. It pays the dealer to handle machine-made tea, because the demand is created by just such striking and suggestive and announcements as that on page 9 of this issue.—*American Grocer*, Sept. 1.

COFFEE CROPS—1897-98.

It is estimated by W. H. Crossman & Brother that the coffee crops of the world in 1897-98 will be about the same as during the 1896-97 crop—that is, a total of 14,000,000 bags, divided by about 3,500,000 for Rio and Santos and 5,500,000 for all other countries, with the possibility that one may be more and the other less, but the total not far from the figure mentioned. If low prices stimulate consumption this year as much as they appear to have done in 1896-97 it will tend to check a decline to the low prices of 1882, when a record of 5½ cents was made for ordinary, and No. 3 (or fair Rio) sold at 7½ cents. If this year's total supply is as large as estimated it may be that the market will drop to prices made fifteen years ago.—*American Grocer*, Sept. 1.

JAVA CINCHONA SHIPMENTS.

The exports of cinchona-bark from Java during the month of August have been declared at 697,000 Amsterdam pounds. The following figures show the totals for the past five years up to the end of August:—

	1893	1894	1895	1896	1897
Month	Amst.	Amst.	Amst.	Amst.	Amst.
of Aug.	lb.	lb.	lb.	lb.	lb.
August	636,000	853,000	697,000	979,000	697,000
January					

to Aug. 5,376,000 5,554,000 5,013,000 6,029,000 5,005,000

These figures have created a favourable impression at Amsterdam, and raised expectations of a better unit for the coming auction, at which a small quantity only will be offered. It is rumoured that the German combination of manufacturers contemplate an advance in the price of quinine. The Java works are looking for higher prices, but the figures they quote contradict the conclusions they arrive at in their reports, which state that they are enlarging their capacity to 100 kilos per day.—*Chemist and Druggist*.

PLANTING IN JAVA, STRAITS SETTLEMENTS AND B.N. BORNEO:

THE VISIT OF AN EXPERIENCED CEYLON PLANTER.

At our request, Mr. A. E. Wright, the well-known Ceylon proprietor and Inspector of Estates, has written the following interesting account of his recent trip to the "Far East":—

I left Ceylon on the 5th July 1897, arrived at Singapore on 10th July, left there for Batavia on 13th July, where we arrived on the 15th July, and on 16th went on to Buitenzorg. Mr. and Mrs. Dunsmore and Mr. Welldon accompanied me so far and they went back by steamer, via Batavia, Samarang, &c., while I went up to

THE PREANCER

to visit my interest, there I found everything very flourishing.

Mr. Dunsmore, Mr. Welldon, Mr. Bingley and self, visited a Mr. Motman's

LIBERIAN COFFEE ESTATE

together, the day we were at Buitenzorg, and it certainly was a sight worth seeing, the soil, and growth of trees, and crop was magnificent, and his factory arrangements very complete, and as for his bungalow it was good enough for a Governor-General! You can fancy my surprise at finding a telephone wire connecting Tji Wangie estate with Tji Rengas Station (the rail and telegraph station) a distance of ten miles, for the cost of which we pay 20s a month to the Telephone Company, and they pay cost of plant, erection and for keeping it in repair. In this particular Java is far ahead of Ceylon. Some estates have telephone communication with each other thirty to forty miles apart.

I left Java for Singapore on the 23rd July, arriving there on the 25th and finding that there was no steamer for British North Borneo until the 3rd prox. and on Sir Charles Mitchell's recommendation I took a run up to the Native States, the result of which, was that I applied for a block of 640 acres at

KUALA SELANGOR,

which has been granted to me on very favourable terms, for coconuts, &c. I was not very favourably impressed with the land between Klang and Kuala Lumpur, through which the railway runs, but I was told that this was not a fair sample of the land at all, but had not time to

visit the better parts. Kuala Lumpur is a very pretty place, and their public buildings would do credit to a town twenty times its size, Mr. Spooner has certainly left his mark there, as I believe he designed and built these buildings by the P.W.D., they are of Moorish architecture, and very beautiful, and well finished.

After spending a few very pleasant days at Kuala Lumpur, I returned to Singapore on the 4th September to find my steamer did not sail until the 6th, when I started for

B.N. BORNEO.

Arrived at Labuan on the 9th, spent one day there, left for Kudat on the 11th, arrived there on the 12th, spent two days there, and went on to Sandakan, 14th, arriving there on the 15th left for "Sahad Datu" in Darvel Bay on the S.E. side of B.N. Borneo and returned to Sandakan on the 19th and spent four days at Government House where Mr. and Mrs. Beaufort were extremely kind to me, and made my visit a very pleasant one. On the 23rd I left for Maruda Bay in Kudat, where I found some very fine land, and visited some tobacco estates as well. I also saw some good land in Darvel Bay. Returned to Ceylon, 12th Sept. At present the B.N. Borneo Co. have only touched the fringe of the country; the interior is yet unknown. There are great possibilities for this country, but they want men and money to develop it; a young fellow with £2,000, and his head screwed on the right way might do well there with coconuts, &c.

FORESTRY IN THE ISLE OF MAN.

We have received, from the genial editor, a copy of the Journal of the Isle of Man Natural History and Antiquarian Society, published on September 2nd, 1897, edited by P. M. C. Kermodé (M.B.O.U., F.S.A. Scot.), Volume III., Part V. This pamphlet covers a year's proceedings of the Society, and includes a full account of the very successful and instructive British Association Excursion in September last year, in which we took part and the memory of which will always afford us pleasure. But we do not mean to refer to this nor to the many attractions—archaeological, geological, botanical or geographical—connected with the Isle of Man and recorded in the pages before us. We wish rather to make one quotation of some practical concern to Planters in Ceylon who are interested in forestry and who should note the very large number of trees (5,500) planted per acre in the Isle of Man in experimental plantations and the object with which this was done. At an excursion to Archallagan, 10th July 1896, (Leader, Mr. G. W. Lamplugh, F.G.S.) we read:—

"Mr. Drinkwater was called upon for some particulars of the experiment of planting the waste land of the Island with trees. Archallagan Plantation was, he stated, planted in 1883 by Lord Loch, being one of a series of three Government plantations—this the earliest, next in order of date South Barrule, and the latest Greeba. Archallagan is about 381 acres in extent, and about 5,500 trees were planted per acre, or in round numbers over two million of trees at the first planting. Of the trees per acre there were of Larch 1,368, Scotch 1,368, Austrian 684, Corsican 684, Spruce 350, and Silver Fir 350, and the remainder hard woods—Oak, Turkey Oak, Sycamore, Ash, Elm, Birch, Beech, Alder, and a

few Mountain Ash. The hard wood has almost entirely disappeared. The principle of modern scientific planting is to keep the trees so thick that the branches die off and clean symmetrical boles are formed, the trees being supported by the air space above them rather than laterally. It becomes, therefore, important to consider the relative speed of growth lest one tree should overtop its neighbour, and so stop its growth. In Greeba the trees have been further arranged in groups so that the colours may stand out in the landscape—by which he meant that the principal trees are so placed that when the nurses are thinned out, the remainder will produce a distinct effect—mass by mass. A further point of interest is that the ash and sycamore have been placed to the best advantage for naturally seeding the plantation. Turning again to Archallagan, the speaker continued: You will notice patches where the trees are not crowded, according to my statement of the principles of forestry. You may attribute these either to the character of the soil being unsuitable, or to the fact that the drainage in the particular place is deemed too costly to be worth doing. As to the future value of the plantations, a good deal depends upon whether or not the yield of timber is in excess of the demand or the reverse. Until comparatively recently there has been a reckless destruction of timber. Now, in Switzerland, and I believe in Norway and America, there are regulations about replanting so many trees for each one cut down; and in India great attention is being devoted to scientific forestry. The age is such an inventive one that if the supply runs short before these trees arrive at maturity in some 50 or 60 years' time, some substitute for wood is sure to be forthcoming, and even already paper is used to some extent instead of wood. The Government plantations here are in a purely experimental stage, and are in consequence the more interesting."

THE DEMAND FOR CEYLON TEAS.

The figures given by Messrs. Gow, Wilson & Stanton in their "blue circular" issued by us yesterday, showing the consumption of teas in the United Kingdom and Export for the first eight months of 1897 as compared with 1896, are very satisfactory as far as "Ceylons" are concerned. The "home consumption" in the period named was 55,951,359 lb. against 52,397,003 lb.—or an increase of 3,554,356 lb. This amount is, in excess of the increase in imports; but apart from it there is also an advance in the quantity taken for Export, thus:—

Export of Ceylon Tea from U.K. Jan.-Aug. 1896-7

	1897.	1896.	Increase.
Continent of Europe..	3,692,683	2,826,899	865,784
United States ..	1,337,406	950,229	387,177
Canada ..	1,095,543	825,553	269,990
Other Countries ..	711,841	603,854	107,990

Total lb. .. 6,837,476 5,206,535 1,630,941

The total demand-increase, therefore, for the eight months may thus be given:—

	lb.
Home Consumption ..	3,554,356
Export ..	1,630,941

Total .. lb. 5,185,297

while the comparative increase in imports was only 3,037,726 lb. This is decidedly satisfactory.

THE MANURING OF TEA.

There is, perhaps, no direction in which money can be more easily wasted in connection with the cultivation of tropical products, than in the purchase and application of manures. Not only should the fertiliser purchased be tested by the analyst; but also the soil to which manure is to be applied. The planter should know what is required for his tea-fields, as well as the exact value of what he is buying and its suitability to his own particular case. This is the more especially necessary in Ceylon because of the great diversity of soils in our tea-planting districts. Not only does one district differ from another; but it may be that adjacent plantations require very different treatment. But there is the great temptation among planters to follow some one particular lead; or there is the feeling that for Ceylon tea bushes, "bones and castor cake or fish manure" cannot fail to do good. Possibly not; but it is equally certain that a previous examination of the soil might supply information which would lead to considerable economy or to a great deal more lasting benefit from the application of fertilizers. A planter will tell you, "I have experience to guide me—look at the great improvement in that field I manured last year as compared with its neighbour: I cannot do wrong in following its lead all over the plantation." Now one of the greatest temporary changes we ever saw on a tropical upcountry field arose from its having been all holed ready for manure which never came from Colombo,—so after a few weeks or months, the holes were filled in again, and the apparent benefit in the fresh show of vegetation some months after could scarcely have been greater if an expensive manure had been applied; but the good was but a fleeting one, and we merely mention this to show how unsafe it is for the planter to go by mere appearance. Fortunately, so far as the testing of manures sold in the Colombo or Indian markets goes, a good deal more use has, of recent years, been made of the scientific analyst, and guaranteed analyses are now generally furnished with any considerable quantity of manure purchased. What is wanted now is that the same care should be taken to have the soil examined, and as far as possible to adapt the manure to the needs of the field. But scientific men are the first to confess that guidance by analysis alone is not sufficient. Experiment and observation have also their part to play; only, we have long felt that certain clear directions were wanting in connection with manures of recognised value, to enable our tea planters to make for themselves the needful experiments according to the rules recognised by the best cultivators.

Such clear directions, and a great deal of valuable information, have just been brought together in a Report drawn up by Mr. Cochran with reference to certain standard manures for which Messrs. Freudenberg & Co. are agents in Colombo. This Report, with the clearest possible directions as to the needful experiments in fields, acres, or half acres—counting by bushes—or even smaller plots of trees, is given by Mr. Cochran, so that the planter can make his own experiment with a variety of mixtures named, and compare them alongside of similar experiments with the hitherto more commonly recognised fertilizers for our tea fields. The expense of such experiments need be comparatively little. We are much pleased that this opportunity is made so readily

available through the pamphlet about to be published and circulated very widely. We need not, therefore, quote from it; but we would urge every proprietor and manager in the island to take its teaching into consideration and to endeavour to make some, at least, of the experiments defined. In this way we should have the whole question of manuring put on a scientific basis—a result that could not fail to be vastly beneficial to the whole planting community.

THE AMERICAN TEA MARKET.

To the Editor of THE HOME AND COLONIAL MAIL.

SIR,—Your correspondent "Noreih" advocates the formation of a syndicate to take over the crop of two or three estates at a fair average price, and with the aid of an expert to prepare tea for the American market.

He thinks it is useless to contend in America for an adequate share of the market for our teas on their merits, but says that he is of opinion that the old-fashioned panned and soft liquoring teas are more of the kind to "catch on" in America.

I do not think that your correspondent is correct in saying that this market was gained by making a special tea to suit its requirements. My impressions are that the market only took very gradually and unwillingly to Indian tea.

I do not agree with "Noreih" as to the policy of making green tea to suit the United States market. Such an attempt to make something resembling Japan or China tea would be sure to end in failure, and would result in having on hand a tea unsuited to any other market, if the United States people declined to buy it, as they probably would. I know of one such attempt to make a light unfermented tea, which was said to be just what was wanted, but, strangely enough, no one cared to buy the parcel of 50 chests.

We have infinite varieties of black tea, soft or rough, weak or strong, from different districts to choose from, and in time no doubt the Yankees will take to our tea, if we continue to offer them our machine-made sorts in place of other kinds prepared by the use of hands and feet.

The actual imports of Indian and Ceylon teas during the year 1896 were 9,681,040 lb. while the imports for the first six months of the present season, ending June 30, 1897, are 6,249,608 lb. or about 66 per cent. increase over last year's imports to same date. These figures have been published by accepted authorities, and are taken from a letter dated New York, September 2, 1897, addressed to the editor of the *Journal of Commerce* by Mr. Richard Blechynden.

They show that progress is being made in the United States.—Yours truly, ANGLO-INDIAN.—*H. & C. Mail*, Sept. 17.

CEYLON TEA SHARES AND PROPERTY
IN THE LONDON MARKET:

GOOD ADVICE TO CEYLON PLANTERS.

A Correspondent, much interested in our teas and the prosperity of Ceylon, writes from London by a recent mail:—

"The uncertainty of exchange is playing havoc with the tea share market and has curtailed business, for people are doubtful of the effect upon dividends. When the market gets into the present state it is very difficult to realize as so few Ceylon Companies are quoted on the Stock Exchange, and business thereby entails a great amount of correspondence to bring buyers and sellers together. I think however the stringency will be only temporary, for tea is slowly moving to higher values.

"You should, however, waken up Ceylon Planters to the necessity of paying greater attention to manufacture for comparing them with that of India they are not in it as to superior fermentation, rolling and grading of their teas. The broken pekoes of Ceylon, which at one time would have been taken readily by the trade, are now neglected by the larger wholesale houses in consequence of their dusty and broken condition and therefore cannot mix with their higher class of blends and their forces the price down to the inferior grades. I send you four samples, two of desirables and two of undesirable broken pekoes with this relative values. These you can show to any enquirer. I also send four samples of Indian teas for comparison. It is not a matter Ceylon men should shut their eyes to, for the competition with Indians will become keener, because the liquor from Indians is superior to anything from Ceylon, and it is only by careful manufacture on the part of the Ceylon planter that he will maintain his ground and raise his teas to a higher value. At last sale some Ceylon teas were sold at 2^d and how any one could think of a profitable result from such tea is a mystery, for it would have been better to have put it into the furnace.

"Mr. John Hamilton's advice about packing teas and weighing of packages was deserving of more attention than it apparently received in Ceylon. So long as they remain blind to what materially affects their own interests, no improvement can be looked for. In the early days of Ceylon tea cultivation they showed the way to India, but now they are losing ground and should waken up.

"The value of tea properties, of course, has likewise been affected by the position of exchange and value of teas—to the extent, I should think of 30 to 40 per cent and the high prices lately paid need not be looked for, for a considerable time as Company promoters will not take up anything less than 10 per cent on present results. Several Companies lately floated will have a hard struggle to make ends meet if the present position of affairs remain long as it is."

CLOVE CULTIVATION AT ZANZIBAR.

From "The Shamba" or "Journal of Agriculture for Zanzibar" for Sept. 1897 we quote as follows:—

Our Pemba correspondent writes as follows:—I believe the clove crop as a whole is a very poor one, but I have noticed that when there is a clove tree close to a hut where the ground is kept more clear of undergrowth, and the refuse from the hut is thrown near clove tree, the crop of cloves is 4 or 5 times as great as on ordinary trees. In fact the tree is full of buds. This seems to show that careful cultivation and manuring will greatly increase the yield of cloves. Some of the trees that are being picked are very much damaged already, which will probably injure next year's crop. The buds are still being dried in the old rough and ready way. Nevertheless I have found some very nice clean and dry samples of cloves which if they could reach the market in their present condition would sell well.

I have been making some experiments in drying cloves in a small way with interesting results, though of course further experiments might show my present conclusions to be worth very little. So far, I incline to think that the buds should be gathered *pink*, not *red*, or else they will burst open in drying. They should be dried in plenty of air and wind with some sunshine. My best sample No. 4 is about equal to Penang but small. The samples were gathered in a

very poor plantation and the buds were small to begin with.

EXPERIMENTS IN DRYING CLOVES IN PEMBA, AUGUST 1897.

No.	CONDITION.	METHOD OF DRYING.	RESULT WHEN DRIED.
1	Red and fully grown buds but not opened.	Under cover from rain and dew, but exposed to air and wind and about 5 hours sunshine per day.	About 20% opened into flower 10% of the flowers came right out. 75% were striped and spotted with light brown lines on lower part. Sample poor.
	Pink.	In broad daylight with all obtainable air and wind but no sunshine.	None damaged. Heads brown other parts chocolate colour sample good but small.
3	Almost Green.	Same as No. 2.	None damaged, heads brown other parts darker than No. 2 and rather smaller, otherwise good.
	Pink.	Same as No. 1.	None damaged, heads light brown other parts reddish brown—also rather small—Best sample—except for size about equal to "Penangs."
	Large and Red.	In dull light with free air but no wind or sunshine.	About 6% opened into flower 30% discoloured with light brown lines and spots—the rest almost black. Sample large but poor.

Nos. 2. 3. 4. Were gathered from a poor plantation and were small buds.

COFFEE IN WESTERN AFRICA

has begun to suffer much from "borer." The following is from "Kew Bulletin":—

Extract from a letter, dated, Aburi, 6th January, 1896, from the Chief Justice to the Governor. I came up here on Saturday, and on Sunday morning I looked round the coffee. It is in a deplorable state. The Arabian coffee apparently likes the soil and climate, but is literally ruined by (I think) a boring grub, which enters near the bottom and makes a hole rootwards, thereby doing fatal injury to the trees. Practically all the Arabian coffee looks wretched. I never saw anything looking better than the Liberian coffee. It looks superb. On closer investigation I found about two trees out of five attacked by a boring grub, different, I think, from the grub which attacked the Arabian coffee. This grub has only lately begun to attack the Liberian coffee, and you can see trees laden and breaking down with fruit getting yellow from the effects of the grub; some are dying, some dead, all due to the boring grub. The natives see or will soon see it, and will abstain from planting coffee. Considering that this is an agricultural country, and that soil and climate appear to suit the Liberian coffee to perfection, something should be done to try and defeat the grub.

On specimens and information sent him, Mr. Walter F. H. Blandford furnishes a long report to the Colonial Office; much of what he writes is familiar to us in the East, but there can be no harm in repeating hints that are of use in

respect to the insect enemies of more plants than coffee :—

The following points in the life-history of the borer should be accurately made out :—

The *season* at which the perfect beetles appear. This will probably stand in some relation to the dry and wet season.

The *habits* of the perfect beetles, their flight time, place of rest during the day; their tendency, if any, to frequent flowers, oozing sap, diseased trees, &c.

The *place* at which they *oviposit*. This is of importance. Probably oviposition is favoured by wounds in the bark. Special attention should be paid to the probability of the eggs being laid at pruning wounds, and the system of pruning adopted should be looked to with this object.

The *length of larval life* and the length of time a tree will withstand injury without succumbing should also be investigated.

The *early signs of injury* should be carefully made out, in order that infestation may be detected as soon as possible.

General Suggestions.—The following general suggestions for treatment over and above those already given are based mainly on the assumption that information will be gained on the above points.

Prevention of Egg-laying.—All pruning and accidental wounds should be tarred. Possibly egg-laying may be prevented at the usual situations by plastering the part of the bark usually selected for the purpose with clay and cow dung, or a similar mixture, or painting it with lime-white mixed with rice water, to make it adhere. This treatment has proved successful with other species of borers.

Capture of the perfect Beetles.—This to be successful must be attempted after study of their habits and time of appearance. It may be done :—

(a.) By placing sheets under the bushes, and shaking off the beetles, in the early morning or whenever they are so sluggish as to drop. The beetles should then be collected and killed with boiling water.

A convenient plan of collecting them from sheets is to fit a tin bucket with a wide funnel-shaped lid of tin, furnished at the centre with a short tube. The sheets are shaken on to the lid, the beetles drop through the tin tube, and cannot escape until the lid is removed.

(b.) By setting baits for them, and collecting them from the baits. This cannot be done unless their habits show that some kinds of bait will serve to attract.

(c.) By providing logs of any tree which they will attack, ringed trees, coffee shrubs which have been condemned and are dying or have been ringed for them to lay their eggs in. These "tree traps" should be provided before the flight period and removed before the beetles in them have bred out, or they will do more harm than good.

Preservation of attacked Shrubs.—This can only be done, if at all, by attentive examination so as to detect the early signs of injury when the larva is still feeding under the thin bark. That these early stages can be detected with practice I have little doubt; whether it can be done with sufficient rapidity to make it practicable is more questionable. If such a patch is detected, the bark should be cut away and the larva tumbled out; it will soon die if exposed to the air and light. The cut part should then be tarred. If the patch has been opened after the larva has finished its superficial burrowing, and gone deep into the wood, it might possibly be killed with a wire, or by wetting the burrow with kerosene, which will penetrate. But these methods are not very practicable, and I regard the surface burrowing as the most important. With the exception of these methods the larval and pupal stages are not open to measures calculated to get rid of them. The suggestions made in the foregoing pages cover all the points by which success in the treatment of the borer appears to me likely to be obtained. That they are all practicable under local conditions is unlikely; but they are all measures which have proved of service in other countries and with other host plants

Particular attention is drawn to the necessity for investigating the antecedent causes which may have favoured the infestation, to the desirability of studying the relation of shade-trees to the infestation, to the great importance of destroying all woody material, shrubs, &c., which may harbour the larvæ and are past recovery, to the importance of attending to pruning wounds, and of catching the perfect insects by shaking down.

PLANTING NOTES.

"ROYAL GARDENS, KEW."—Bulletin of Miscellaneous Information. Contents for April is as follows:—DLIII.—Mycologic Flora of the Royal Gardens, Kew; DLIV.—Spindle Tree; DLV.—Miscellaneous Notes; Sir Robert Meade; Sir John Thurston; Seed Distribution; Botanical Magazine; Flora of British Central Africa; Drift Seeds from the Keeling Islands; Algae in the Kew Herbarium; Broom Root; Snowdrop disease; Canna disease; Double Rice; Sorghum Sugar. Bulletin of Miscellaneous information for May and June has the following contents:—Insects destructive to Plants in West Africa; Fruit-growing at the Cape; Canaigre; Extraction of Gutta Percha from Leaves; Wine Production in France; U.S. National Herbarium; Completion of Flora of British India; Miscellaneous Notes. Bulletin of Miscellaneous information for July 1897, has the following contents:—Marram Grass; Agricultural Depression; Fat Hen in Australia; Eucalyptus Timber for Street Paving; Grafting Sugar Cane; Grama Grass; Flora Capensis; Hand-list of Tender Monocotyledons; Fiji Ivory Nuts; Additions to list of Kew Publications, 1841-95; Miscellaneous Notes. Bulletin of Miscellaneous Information. Contents for August and September are as follows:—DLXXV.—Diagnoses Africanae, X; DLXXVI.—Miscellaneous Notes; King of Siam; Botanical Magazine; Key Plan; Water Lily Pond; Tampico Jalap.

TIMEHRI.—The Journal of the Royal Agricultural and Commercial Society of British Guiana, June 1897, edited by James Rodway, F.L.S. Contents:—Papers.—Nesting of some Guiana Birds, by C. A. Lloyd; Early English Colonies in Trinidad, by Hon. N. Darnell Davis, C.M.G.; Agriculture in 1829, by William Hilhouse; First Impressions of the Colony, by W. Arthur Sawtell; Tobacco and Cotton Cultivation in the British West India Colonies, by William H. Burnley; Ruin, by the Editor; The Result of Recent Scientific Researches into the Agricultural Improvement of the Sugar Cane, by J. B. Harrison, M.A., F.I.C., F.G.S., F.C.S., etc.; The Life History of an East Indian in British Guiana, by the Rev. J. G. Pearson, Note on the Arrangement of Sugar Cane Experiments, by J. B. Harrison, M.A. &c., &c. Reports of Society's Meetings, from January to June, 1897.

MR. CHAMBERLAIN AND SISAL.—It was recently reported says that Mr. Chamberlain had abandoned his sisal plantation in the Bahamas as a losing speculation. The annual report of the Governor, Sir W. F. Haynes Smith, which has just been issued, tends to confirm the general impression that a number of people burnt their fingers over this extravagantly-boomed West Indian industry. The Governor observes:—"The cultivation of sisal plantations is abandoned in some places, whilst in others it is reported to be on the increase. The prospects for this new industry are now becoming more defined, and although it has absolutely failed to fulfil the anticipations once formed of it, there seems to be less reason to fear that it will die out altogether, and some reason to hope that it may in time become a small but well-established industry returning fair profits to those engaged in it. Pine-apple cultivation in the islands is more promising." The Governor reports this industry to be increasing and that large growers are making substantial profits.

COPPERAH GOES UP IN PRICE.—The market in this article has suddenly risen and there is a stiff competition between millers and shippers. The sudden rise is due to the presence of a new buyer in the person of a Nattukotta Chetty, who is purchasing largely for the Calcutta market; which last week remained steady at R39.75 per candy. The Chetty in question suddenly ran the price to R40.75 and the wily boatmen are keen on holding to the new price, demanding the same from their old customers.—Local "Independent."

THE COUNTRY NORTH OF KURUNEGALA.—A gentleman interested in the Northern Commission's line of railway, but who has we believe, not been over the ground, writes:—

"People who see no value in the land north of Kurunegala forget that there is there soil, climate, and rainfall, such as would be admirably adapted to the growth of such an article as cotton."

But far better soil and the very climate for cotton is that found between Anuradhapura and Manaar—the "black cotton soil" of Tinnevely being repeated in part of the Manaar district.

"TOON" TREES.—We are often asked about these and their success in Ceylon. Here is information from a practical planter who has had as much to do with them as any man in the island:—

"There are two varieties of Toon pretty common in Ceylon. One is Cedrela Toona which is generally supposed to be the red, toon but I understand that is the name of the white variety which has been a failure all over the country except at Peradenia, where the late Dr. Trimen said it was a far finer tree than the other. The name of the red variety is Toona Serrata and I think it a very nice tree for wind belts especially if intermixed with grevilleas and the timber is said to be very useful indeed, but I doubt if much or any has so far come into use here."

MANURES AND MANURING (Indian Manures).—The "Agricultural Ledger" 1897—No 8 deals with Indian Manures, their composition, conservation, and application. Anote by Dr. J. W. Leather, agricultural chemist to the Government of India. The materials dealt with are the materials which are more or less available to the Indian cultivator may be included in the following list:—

1. Cattle Dung and Urine
2. Cattle Bedding materials
3. Night-soil and other city refuse
4. Oilseed refuse
5. Bones
6. Saltpetre
7. River, Canal and Tank silt
8. Green manures
9. Influence of Leguminous crops
10. Sheep folding.

A NEW SOUTH WALES FORESTER ON TREE GROWING IN CEYLON.—We direct the attention of planters and others to a letter from Mr. Rudder of New South Wales in another column. His impressions of our hill-country and timber-growing are worth having. An upcountry correspondent writes:—

"A gentleman who has been paying us several visits in the past two weeks is a Mr. Augustus Rudder of Sydney, U. S. W., who on his way back from the Jubilee celebrations in London broke his journey at Colombo so as to have a fortnight in Ceylon. Mr. Rudder having served the Government of N. S. Wales for many years in the Forest Department, naturally saw a good deal to interest him in Ceylon. He is to leave Colombo this week by the 'Oruba' for what he now considers his home in N. S. Wales, where, though not born there, he has spent 64 years of his life."

Mr. Rudder, it will be observed, recommends two trees that are comparatively new to us—one a Eucalypt and one a Cedar—*E. pilularis* and *Cedrela Australis*. Has Mr. Noek of Halkgala or Mr. Fraser on Abbotsford got either of these growing?

EXTRACTION OF GUTTA PERCHA FROM LEAVES.—The following communication supplements the information already given in the *Kow Bulletin* (1891) pages, 231-239. Extract from letter from Director of Gardens and Forest Department, Straits Settlements, to Royal Gardens, Kew, dated Botanic Gardens, Singapore, September 18th, 1896:—"I have been down to inspect the little factory where Mr. Arnaud makes his gutta-percha. Serullas has gone back to Paris with endless patents of different kinds, and Mr. Arnaud alone keeps up the business. The leaves are imported in sacks dry from Borneo and Johore. Most of the trees are over-cut in Singapore, and there are no more leaves left, I hear. The leaves and twigs cost four dollars and a half a picul (133 lb.). They are then put, damped with hot water, into a rolling machine, two rollers working against each other, which grind them to powder. The powder is thrown into tanks of water and shaken about. The gutta floats in the form of a mealy-looking stuff, is lifted out by fine copper gauze nets, put in warm water and pressed into moulds. I have samples of the gutta as it comes from the caves, and the pressed out finished article. It is really a very curious little manufactory. I do not know how long it will last, on account of the difficulty of procuring leaves, which must, I think, sooner or later stop the trade."—*Kow Bulletin*.

THE INDIAN TEA CROP, 1897-8.—We published the other day a special telegram from Calcutta announcing that the estimate for the current year's crop was reduced to 148 million lb., of which 130 million were expected to go to the United Kingdom. But nowhere has the original estimate been quoted to show the actual reduction now anticipated. This is no less than 8,669,112 lb., for the estimate framed in June last gave a total of 156,669,112 lb.—Our evening contemporary was between 7 and 8 million lb. wrong in the figures he gave the other day for the "total output" of the 1896 crop. According to Messrs. Wm. Moran & Co.'s return of 1st June last, the actual crop of 1896 was 148,217,416 lb. of which 16 million lb. went to the Colonies and America. It will be seen, therefore, that the Indian crop for the current year is not expected to exceed that of 1896; while the shipments to the United Kingdom may be 2 million lb. less! Here are the details published on 1st June last:—

We are favoured with the following figures by the Indian Tea Association:—The General Committee have now the pleasure to hand you the following figures showing an estimate of the Indian tea crop 1897.

	ORIGINAL ESTIMATE OF CROP OF 1897.		Actual Crop.
	lb.	1896.	1896.
Assam	63,359,989	59,655,793	
Cachar	21,540,153	20,401,487	
Sylhet	26,762,000	25,099,486	
Drajeeling	7,644,250	7,817,495	
Terai	3,734,000	3,738,927	
Dooars	24,209,720	22,073,781	
Chittagong	919,000	1,030,125	
Chota-Nagpore	320,000	220,322	
Kangra	2,180,000	2,180,000	
Dehra Dun and Kumaon (Estimate)	2,400,000	2,000,000	
Private and Native Gardens (Estimate)	4,000,000	4,000,000	
	156,669,112	148,217,416	

being 8,451,696 lb. over the actual outturn of the crop of 1896. Estimating shipments to America, the Colonies and other ports with local consumption at 18 millions (or say 2 millions more than last year) there will remain about 138½ million lb. for export to Great Britain.

Revised Estimate:—
 Total Output 1897 = 148,000,000
 „ to United Kingdom = 130,000,000

“TEA MANUFACTURE BY ELECTRICITY.”

The first issue of the new series of the *Indian and Eastern Engineer* is an *édition de luxe* printed on toned paper with numerous illustrations and much instructive letterpress. The most interesting article to us is on the above topic, and we quote it as follows:—

Mr. David-on Rickie, Electrical Engineer to the British Darjeeling Tea Co., Ltd., has successfully introduced electricity as a motive power for the manufacture of tea. This we believe is the first instance in which electricity has been introduced with success for tea manufacture.

Mr. Rickie is also the patentee of a process for the complete manufacture of tea without the aid of fuel, where water power is available within reasonable distance from a tea factory. The value of this can hardly be overestimated when one considers the thousands of acres under tea cultivation, and the numerous gardens with water power available. A wide field for electrical enterprise, and a bright future for electricity in this direction, has now been opened out, and those who are interested in tea will not be slow to perceive the great advantages electricity holds over any other motive power. We will enumerate the advantages hereafter, and, for the present, confine ourselves to a descriptive account of the electrical plant which has been steadily at work from the beginning of 1896, and has proved to be a conspicuous success.

The Thurbo Tea Estate, which covers over 3,000 acres, belongs to the British Darjeeling Tea Co., Ltd., and extends from the Mechi River (one of the Nepal boundaries) to the Rungbong River, which flows through the Nagri Valley. The tea factory, of which we give an illustration taken from a photograph, is situated one mile from the Rungbong River at an elevation of 4,000 feet: all the machinery is worked by electricity. The water taken from the Rungbong River, is led by a substantial waterway of masonry to a point where a fall of 56 feet is obtained; from this point 16-inch steel pipes convey the water, down the 56 feet fall, to a 40 H.P. Jonval Turbine (this being one of the best low-water fall horizontal turbines, by Mr. William Gunter).

To this turbine is connected, by belt and pulley, a Messrs. Mather and Platt's Patent Manchester Dynamo capable of generating 30 B. H.-P. indicating 320 volts and 70 amperes. The current of electricity is transmitted by overhead copper wires to the factory; the terminals being connected to a Manchester motor, patented by Messrs. Mather and Platt, and capable of developing 24 B.H.-P. The motor is under complete control, and the speed is regulated by a graduated 10-stop switch; it is also supplied with drop sight oil cups, and Messrs. Mather and Platt's patent carbon brushes, so that, practically speaking, it requires no attention. We learn that this enterprising firm of electricians have further enhanced the value of their electric plants for tea manufacture by their recent patent enclosed motors, which protects the motor from all tea dust. Among other useful productions are their patent automatic brushes, which are absolutely necessary for the varying loads resulting in tea manufacture, during the rolling process.

The machinery driven by the above electric plant comprises—2 Large Davidson Down Draft Sirocco tea driers; 2 Jackson's Patent tea-leaf rollers; 1 Davidson-MacGuire tea packer; 2 Tea sifters; 1 Tea cutter. It also provides for the lighting of the factory throughout by electricity with numerous 16 C.-P. incandescent lamps which are hung from the ceilings and give a brilliant light. The electric lighting of the factory is effected by joining the positive and negative wires for the electric light, to the positive and negative wires between dynamo and motor; the current being regulated by a small resistance box.

The entire confidence which the British Darjeeling Tea Co. place in Mr. Rickie's abilities, and the reliance they place in electricity as a

motive power of tea manufacture, is proved by the fact that there is no reserve power at hand in the event of a breakdown; and no doubt can be entertained of the success of the above plant, seeing that such satisfactory results have been obtained, and it is now well through the second season, with no sign of any trouble or stoppage.

We will proceed to enumerate the many advantages to be derived from electricity, as a motive power, for tea manufacture. Firstly, we must consider that most serious question of fuel, always a difficulty, but more specially in the Darjeeling District, where it is difficult to obtain firewood owing to the stringency of the Forest Department, and the enhanced rates for freight on coal on the Darjeeling-Himalayan Railway, and the trouble and cost of carriage of fuel from railway to the tea gardens, Electricity has a great number of advantages over the old style of generating motive power by a steam boiler with its great cost for fuel, when, as is the case with most gardens, Nature is ready to supply ample power, constant and never-failing, in the form of abundance of water, which is running to waste.

It certainly seems almost incredible that those who are striving daily to reduce expenditure, and study economy, on a tea garden, cannot see that they are throwing away a large percentage of the profits in smoke; whereas, by utilizing this water power and adopting electricity, a great economy could usually be obtained. There are, at this present time, tea gardens in the Darjeeling District paying R34 per ton for coal, and R30 per hundred maunds for firewood; at the same time they have abundance of water power within easy distance from the factory.

What are the advantages derived from steam power? Coal or wood is absolutely necessary. There is the constant fear to the manager of a tea garden that the native driver may allow the water to run low in the boiler. The fires must be lit at a certain hour to be ready for withered leaf, and after steam is raised and the leaf is not quite ready, the fires have to be kept back.

The boiler has to be cleaned out occasionally and scaled, which incurs the cost of packing, jointing, etc. The yearly overhaul to machinery, viz., steam engine and boiler.

The dirt and dust resulting from the use of fuel. These are all disadvantages, and the only advantage steam can claim over electricity is, that it does not require so large a supply of water. In all other respects, electricity proves to be superior.

It is the acme of cleanliness as a motive power.

It can be started and stopped at any moment, night or day, at a moment's notice.

It will run for years without requiring any repairs.

It is more economical than any other power excepting the water-wheel.

There is the great advantage of lighting the factory by electricity, and most of the disadvantages, arising from the use of steam power, are obviated.

The Superintendent can command the electricity at any moment, as he has only to ring an electric bell, and the man in charge, at the turbine house, turns on the water by opening a sluice door, and in 2 to 3 minutes all the machinery in the factory is in motion. There is no necessity to order more or less power, as the ammeter indicates what machine is at work by the resistance indicated thereon, and the voltmeter indicates the speed by the number of volts. No danger can arise from too great a pressure, as a safety fuse would immediately melt and cut off the current, or, in other words, break the circuit; but this seldom, if ever, occurs, and in the event of it occurring, a fresh fuse is always at hand, which can be replaced in half a minute.

We learn that Mr. Rickie is now making arrangements for testing his patent on a large scale; and should he prove successful it will create a revolution in tea manufacture; and it can only be a question of time for the general adoption of electricity.

Another decided advantage of electrical plants is, the ease with which they can be carried. A dynamo or motor can be taken in parts, and the heaviest of these can be carried by eight hill coolies to the

most inaccessible tea gardens in the hills; whereas it would take days of labour and anxiety, with hundreds of coolies, to drag a steam boiler and engine. As a matter of fact, it has been found to be quite impracticable in some of the hill gardens. We would impress on all interested in tea, who decide to adopt electricity as a motive power, the necessity of having the plant erected, and fitted up, at the outset by a thorough, practical engineer, as the secret of success is that electrical plants must be thoroughly put together, and if this is done they will run for years without giving any trouble.

Many who are not conversant with electricity have an idea that it is a dangerous power; that is a great mistake, as the only danger lies in touching the exposed parts which are charged with electricity, and there is no reason or necessity for doing so; but even should this occur, the only result would be a severe shock, as the power required for a tea garden would not be sufficiently strong to cause any serious accident. It has been very amusing to read in the local papers articles headed "The Dangers of Electricity," the writers of these articles appear to forget that, accidents due to electricity are few and far between, whereas accidents from steam are of frequent, we may say almost daily, occurrence. We are confident that such articles appearing in type will not affect the progress of the electricity, and we are glad to see that our enquiries in our issue of last March, "Notes on Electricity" as to "Whether Electricity had been adopted in any of the Hill Tea Gardens," have brought to light the fact that it has been successfully introduced; and we have no doubt that it will eventually, in the near future, be generally adopted, both in India and Ceylon.

There are three illustrations entitled:—Thurbo Factory, Darjeeling; A corner of the Factory shewing Electric Motor and leaf rollers; The Manchester Motor shewing regulator and electric light connections.

As a *Supplement* to the *Engineer*, there is an extremely good photo etching of the effects of the earthquake on Munshai Bridge, Cooch Behar State Railway. Altogether this issue is a splendid one of the new journal, and we congratulate all concerned on its get-up.

"THE PROSPECTS OF RAMIE CULTIVATION IN PERAK."

MR. L. WRAY'S ESTIMATE SHOWS A LOSS
ON THE CULTIVATION;

MR. E. MATHIEU—A NET PROFIT UP TO
136½ DOLLARS PER ACRE.

MR. J. M. MACDONALD'S ESTIMATED PROFIT,
£25 TO NEARLY £50 PER ACRE!

WOULD THE SOUTHERN PROVINCE OF
CEYLON RETURN £5 PER ACRE PROFIT?

WE have received a packet of papers on the above subject from the Straits Settlements containing information of an exceptionally interesting character. To the literature on "Ramie" Fibre, its cultivation and preparation, there is literally no end. We are heartily tired ourselves of all the glowing reports and circulars issued by interested Companies in the old country,—of the many new processes and patents which are to make the fortune not only of the holders, but of the producers of the fibre; and of the diverse instructions offered by gentlemen who probably never saw a tropical fibre-yielding plant in its habitat, nor did any practical cultivation in their lives. It has, therefore, become our practice to dispose of all fresh circulars or reports on "Ramie" after a very

cursorious inspection; but in the present case we have been assisted by a careful summary of available information prepared for the Perak Government by Mr. L. Wray, junr., respecting the yield per acre, the cost of harvesting and preparing, and finally the value of the result. Here is the information as to yield put into tabular form:—

	Fibre. lb.	Ribbon. lb.
Forbes Royle ..	960	1,280
J. Montgomery (mean) ..	986	1,314
Hardy ..	1,260	2,100
E. M. ..	610	1,080
E. Mathieu ..	1,881	2,508

Mean yield per acre 1,173 .. 1,656

The mean yield of fibre is therefore a few pounds over half a ton, and 739 of a ton of ribbon per acre, that is about 14½ cwt. or 12½ pikuls.

Then as to cost:—

Very little is to be found, in any of the accounts of ramie, of the cost of the cultivation. It is variously stated that one coolie can keep in order 2 to 3 acres of land; while no information is available as to the cost of gathering, boiling, stripping, drying and baling the ribbon. Taking the mean, that is one coolie to 2½ acres of land, or 2 coolies to 5 acres, and the wages at \$9 per month, the cost per annum is \$43.20 per acre, and per ton of ungathered ribbon \$58.45. As I have already said, there is nothing on which to base an estimate of the cost of harvesting and preparing the crop. The process is as follows:—

The stalks are cut near the ground, then stripped of leaves and topped. They are then carried to the boiling tanks and boiled for about a quarter of an hour. The bark is then stripped off by hand, carried to the works to dry, when quite dry it is sorted into lengths, and baled ready for shipment. Considering that some 15 tons of stalks have to be treated per acre, I do not think that less than \$20 could be allowed per ton of ribbon. This would bring up the cost of the ribbon to \$78.45 per ton or \$57.98 per acre.

There is then supervision, manure, rent, duty and buildings. The least that can be allowed for this is \$10 per acre per year. Taking a 500-acre estate this would be made up as follows:—

Rent at 50 cents per acre ..	\$ 250
Supervision, \$300 per month ..	3,600
Manure	500
Upkeep of buildings ..	250
Duty on 369.5 tons at 2½% ..	623

5,223

The final cost of the ribbon would be \$91.97 per ton or \$67.98 per acre.

Summing up as to result, Mr. Wray is not encouraging:—

Dr. D. Morris, the Assistant Director of the Royal Garden, Kew, in a lecture delivered on the 30th November, 1896, gives the price of ribbon as £8 per ton in London. It does not appear that more than £7 (\$67.20) per ton could be reckoned on for the ribbon, and as by the above estimate it would cost to grow and prepare \$91.97 per ton, it would appear that there is a loss of \$4.77 per ton or \$18.30 for each acre of cultivation. There is another side to this question, and that is for the planter to also be the manufacturer of the finished product, in the same way as sugar planters are.

A reply to Mr. Wray's Report came from Mr. E. Mathieu of Singapore who quotes actual experiments made for two years at Buitenzorg, Java, under the control of the Director of Botanic Gardens:—

"One bouw gives four cuttings in one year, weighing in the aggregate 34,000 kilos of green stems, without leaves and topped."

In English figures this works out:—

One bouw (1½ acres)=74,000 lb. of green stems, stripped and topped	
One acre	=42,800 " " "

He next quotes a series of American experiments; but we do not attach much importance to these, though the tabular results of all the experiments quoted may be given:—

I shall now bring together the figures presented you so far, and put them under tabular form:

YIELDS OF RAMIE.

Countries.	Number of years' growth.	Number of outtings per year.	Weight of stems, without leaves and topped, per cutting per acre.	Weight of stems, without leaves and topped, per acre and per year.
Java ..	2	4	10,700 lb.	42,800 lb.
Louisiana ..	3 to 4	2	12,880 „	25,760 lb.
Texas ..	„	2		
California, Kern Valley ..	„	4	12,600 „	50,400 „
Algeria ..	4	3	11,013 „	33,040 „

It will be seen at a glance that while the above figures present very large differences in gross totals of the yearly crops, yet when they are apportioned into separate cuttings they agree very closely; the relative weakness of the weight of the Java cutting, as compared with those obtained in the States or even in Algeria, being explained by the fact that the latter experiments have been carried on for a longer period than in Java.

Mr. Mathieu is therefore inclined to think that after 3 to 4 years a ramie plantation in Malaya should give in 4 cuttings, 20 tons of stems per acre per annum. Such an estimate we consider most unreliable to work on as a permanency, even on the richest soil and with the best possible cultivation. It may be done on a small plot for a few years; but we scarcely think any practical planter—in Ceylon at any rate—would embark capital with the hope of harvesting 20 or 10 tons of a crop per acre, continuously. However let us see what Mr. Mathieu has further to say in respect of the “yield in fibre.” We agree with him as to the great confusion over the different terms used:—

“Yield in Fibre.—Turning now to the yield in fibre, here again we have to brush away the ambiguity attaching to the term fibre. It is dubbed ribbon, raw fibre, clean fibre, dry fibre, filasse—without these words conveying any trueidea of the standard of purity of the fibre nor of its value in money: and sellers of patents or machines have too often availed themselves of the vagueness of the terms used to impose on the public as to the output of their inventions.” Mr. Mathieu adopts “clean dry fibre” and takes as the average of several experiments (chiefly with the Faure machine at Buitenzorg,) an average of 3.75 per cent. He then recapitulates after the following attractive—not to say triumphant—fashion:—

My estimate of yield of ramie stems, stripped of leaves and topped, stands as shown above 20 tons per acre per annum. Green stripped stems yield 3.75 per cent of their weight in clean dry fibre, as sample No. 2, worth £32 in London. Therefore 20 tons of green stripped stems, the aggregate yearly crop of one acre, will give 1,680 lb. of fibre, worth £24 in London. Conclusion: The gross yearly product of one acre planted in ramie in Malaya is £24 in London.

Let us now establish the cost of production of these 1,680 lb. of fibre, and laying them down in London.

ACREAGE, 500 ACRES.	\$
Rent per acre	0.50
Cost of cultivation of 1 acre, trimming and cutting superfluous roots; light hoeings	30.00
Manure (using the leaves and refuse from decortication)	4.00

Cutting, stripping of leaves, gathering and carting 20 tons of stems to factory ..	25.00
Management and superintendence, per acre	20.00
Decortication {	
Cooly labour, 1 cent per lb. of fibre	16.80
Engine-room wages, 1,680 lb. = 3 day's output	6.20
Depreciation of machinery and upkeep ..	10.00
Cost of production of 1,680 lb. at the estate	112.50
Duty 2½% on \$112.50	2.70
Pressing, baling, transport to port of shipment, freight to London, etc., \$30 per ton on 1,680 lb.	22.50

Total cost of 1,680 lb. of clean dry fibre laid in London 137.70

This figure of \$137.70 should be under ordinary conditions considered a maximum; under favourable conditions, and labour at \$6 per month, the expenditure should be much reduced. As it stands, however, it shows that one acre, at a cost of \$137.70, brings in a gross return of £24 or \$240, leaving a nett profit of \$102.30. But it is possible for the planter very materially to increase his profit by partially degumming his fibre himself.

How to gain the last-mentioned advantage with an additional profit of 34.20 dollars per acre, is thus described:—

Degumming, when the gum is yet fresh and fluid, offers very much less difficulty than when it is hardened, as is the case when the fibre is sent simply dried to Europe. Anyone can satisfy himself on this point by boiling freshly stripped ramie in water for, say, one hour; it will be seen that the fibre loses a notable quantity of its gum. If the boiling is kept up for several hours and a small quantity of washing soda added, or soft green soap, the reduction of the gum will be yet more complete; if the boiling is made under pressure in autoclave kiers an almost complete degumming can be obtained; but, beyond the fact that pressure implies more or less complication, it is not necessary nor desirable to carry the degumming so far, because in the presence of a perfectly finished fibre the spinner is apt to suspect the use of injurious chemicals; he prefers, as in the case of hemp and flax, to finish off the process himself with his own particular dressing. The planter, therefore, if he ungums at all, need only concern himself with a partial degumming, limiting himself to extracting, say, two-thirds or three-fourths of the gum.

And then the final conclusion becomes:—

1 acre {	= 20 tons of stems, stripped and topped	
	= 1,680 lb. of clean, dry fibre	
	= 1,344 lb. of degummed filasse	
Cost of production		\$163.50
Value in London		300.00

Nett profit \$136.50 per acre and per year.

Mr. Mathieu further thinks that the best market for the fibre is not Europe but China itself, since while he puts the whole production of ramie (China grass) in China at 11,000 tons, the export is only 2,000 tons, the rest being used for local manufacture.

Finally among the papers sent us is an estimate from Mr. J. M. MacDonald (of MacDonald, Boyle & Co. London,)—“of the Machinery necessary, to decorticate and degum the produce of 1,200 acres of land, and of the profits to be made from the cultivation of Ramie and its subsequent decortication and treatment on the ground, so as to render it unfit for the manufacturer, in which condition it will readily command £42 per ton in Great Britain for large contracts, and much larger prices for small quantities. In France as much as 2 francs per kilo, equal to about £90 per ton, have been offered; indeed at our mill at Long Eaton we are selling the noils or waste at from 4½d to 5d per pound.”

It may be judged from this passage alone that Mr. MacDonald is a sanguine man and that he writes after a magnificent fashion dealing in large figures. He is writing to Mr. T. Gibson, Hon. Secy. of the local Planters' Association :—

In calculating the return from an Estate, I have taken six months as the time required for the plant to mature, but as you are aware, from your experience of Ramie on your Estate at Klang, it matures in three months. I have also taken the product at one ton only for the first six months, but properly planted this may be calculated at 1½ ton, also the product of the second year at 1½ tons, when two tons per acre can be relied upon if the land is suitable. The estimate for machinery does not include buildings. What I should suggest for the consideration of the Planters is that a central factory to degum the fibre should be erected on some suitable spot, and a battery of decorticators placed on each Estate where the Ramie is grown, so that the decorticated fibre only, need be sent to the Central Factory to be treated. Thus an enormous saving in carriage would be effected; the decorticators would be worked by the central factory, and credit would be given to the Planter for the weight of stems decorticated daily, and according to the weight of stems decorticated the amount of his proportion of the profits of the central factory could be determined. The cost of the machinery for the central factory, including working capital for six months, would not exceed £10,000, which will be returned in full with 9 months of the first crop, leaving a considerable profit, and after that the Planters will be receiving at least £25 net profit per acre for every acre under cultivation. By doubling the item for decorticators the output of the central factory could be doubled, the other machinery being equal to the output of 2,400 acres.

We may as well put Mr. MacDonald's sanguine figures on record though we fancy few practical planters will put faith in those referring to returns on working of estate:—

RAMIE IN THE MALAY PENINSULA.

Estimate of cost of necessary Machinery and erection thereof for treating the product of 1,200 acres; 900 being under cultivation, the rest being roads and paths.

Freight, £2 per ton	2,700	0
Brokerage and Landing charges,		
say 2 per cent	1,134	0
		13,552 7

Working Profit 43,147 13

From these profits the Patentees Royalty of 25% will have to be deducted.

For the present we would only note one little point of discrepancy: Mr. Mathieu writing on actual experience bases his estimate for Malaya on a 3½ years to 4 years old ramie plantation; Mr. MacDonald begins operations in six months after planting! It is a pity that planting opinion should, we feel, be prejudiced at the very outset by estimates and figures, which seem to us far too glowing. Far better pleased would practical men be to see a well-considered moderate statement work out a possible profit of £5 per acre than to be met with over £12 per acre profit the first year and well-nigh £50 of working profit in the second year from a cultivation which, so far as we know, no one has yet tried on a scale sufficient to justify reliable estimates for a plantation at any rate in the Eastern world. Garden experiments are useful as guides; but they do not count for serious estimates on a big scale with experienced tropical planters.

The Southern province of Ceylon has been described by practical men as "a paradise for

fibre-yielding plants" and labour in some parts, is abundant and cheap. But we should be sorry to see any one go in for "Ramic" there on an expectation of more than £5 per acre return—and even then the investment would be a venture as all pioneering attempts in the tropics invariably are.

Since writing the above we have seen it stated that Mr. MacDonald has arranged with a native Sultan (Datu Mahomed) to put 1,000 acres under ramic and that a central factory is to be erected to treat the product after the MacDonald-Boyle process. This undertaking and experiment will certainly be watched with the greatest possible interest. Mr. MacDonald has a wide margin to work on, and we wish him all success.

PLANTING NOTES.

PLANTING AND PRODUCE IN TRINIDAD.—The report of Sir Herbert Jerningham of Trinidad shows that the imports amounted to £2,463,325 and the exports to £2,165,820, of which about half in each case belongs to the United Kingdom and the British colonies. Sugar and its products, cocoa, asphalt, and bitters are the chief exports. The total area of the colony is estimated at 1,120,000 acres, of which nearly half a million acres have been alienated, the remainder being Crown lands. The area under sugar cane is 58,500 acres, and cocoa 97,000 acres. The Tobago report, which is annexed to that from Trinidad, is also satisfactory. The revenue exceeded the expenditure, and the island had a balance to its credit at the end of the year. The population of the island at the end of the year was estimated at 248,404, of which East Indians numbered 81,404.—*H. and C. Mail*, Sept. 3.

Fiji.—The last report from Fiji deals wholly with the trade of the islands for the past four years. The trade last year amounted to £677,834, of which, approximately, two-thirds were exports. Of the whole trade more than nine tenths was with, or through, the Australasian colonies, New Zealand taking nearly half the whole and New South Wales the lion's share of the remainder. More than four-fifths of the total trade of the group is carried on at the port of Suva and the remainder at Levuka. The chief imports are drapery, breadstuffs and biscuits, coals, hardware, meats, and a great variety of manufactured goods in small quantities, while the export trade shows an increasing tendency to concentrate around three main staples—sugar, fruit, and copra. When the figures for these are deducted from the whole it is seen that the export of minor products is diminishing. The value of the exports last year was £435,342, of which sugar absorbed £336,929. The area under sugar is increasing, in spite of the unsatisfactory condition of the market, for the sugar industry can only be profitably conducted on a large scale. The export of copra last year amounted to £48,950, which is very much below the average, and only half that of the previous year, while the fruit export—bananas and pineapples, wholly—was £18,490, also a great decline on previous years. But this decline is regarded as temporary only, especially as large areas are being put under fruit cultivation in different parts of the islands. There is a very great number of minor products, the export in most cases being very trifling; the list of them "is more indicative of possibilities than of their fulfilment;" the export of them is "of a more or less casual nature," although there are indications that some, such as coffee and rice, may increase in the near future, as soon as they have supplied the considerable local market which exists.—*London Times*, Sept. 17.

FECUNDITY OF PLANTS.—Your Monday morning "Echoes of Science" made mention—says a correspondent—of the common Purslane (*Portulaca oleracea*), a weed common in Ceylon and known among the natives, who use it as a vegetable for their curries, as Gendakola. The plant is put down as a "botanical wonder" in that the average number of seeds in each seedpod was found to be 6,000. From the following (taken from Rhind's Vegetable Kingdom) it will be seen that there are other plants, which, for fecundity, beat the common Purslane:—"The fecundity of plants, in other words, the astonishing number of germs or seeds which they produce, is one of the causes which are most powerful in facilitating their reproduction, and in affecting their surprising multiplication. A single capsule of the white poppy has been known to contain 8,000 seeds, and a capsule of the *Vanilla* from 1,000 to 1,500: a single stalk of *Zea Mays*, Indian corn or maize, will produce 2,000 seeds; a single plant of tobacco has been found by calculation to possess the almost incredible number of 360,000, and a single stalk of spleenwort has been thought, by estimation, to produce at least a million of seeds."

IS COFFEE "KING?"—In an article under this heading *The Planter* says:—Coorg, doubtless, has for many years past held the premier position in the industry in Southern India, but there is no denying the fact that even there it is now slowly declining. Leaf disease, borer, and bad seasons are, of course, responsible for this falling off. What coffee planters ought to set about is to try and improve the soil which has had all the sustenance it once contained taken out of it by years of continuous planting. It is better to go on opening up fresh land than to persist in planting and replanting that which has borne fruit a thousand fold more than there was any reasonable right to expect, and then to do it at a loss from year to year. While on this subject it may be useful to glance at the Coorg coffee prospects for the current season. According to an official forecast which has just been published, the Coorg coffee crop of 1897-98 is as follows: Estimated yield at $1\frac{1}{2}$ cwt., Europeans 1,984 tons; estimated yield at $1\frac{1}{2}$ cwt. per acre, Natives 730 tons; total 2,714 tons. The average crop during the last ten years has been 3,409 tons; thus the forecast represents only a thirteen-anna crop. Viewed in the light of these figures we feel justified in repeating the question which heads the present article.

YERBA MATE, OR PARAGUAYAN TEA?—In his last report to the Foreign Office Her Majesty's Consul at Villa Asuncion has something to say about Paraguayan tea. He says: "There are two classes sold, but it is only in the manner of preparation that they differ. The kind known as 'Mborovire' is merely dried over a furnace, and then beaten into small pieces with sticks. The 'Molda' goes through the same process, but is afterwards ground in a mill. The export duty on the former was increased in 1895 from 30c paper to 10c gold, and on the latter from 25c paper to 9c gold per 10 kilos. The revenue derived from this source in 1895 amounted to 471,668dols (£16,845). The Yerba forests, called yerbales, were formerly the property of the States, but most of them have been sold, and are now in the hands of a few capitalists and companies. The Industrial Paraguayan Company, which owns about half of the yerbales known to exist in the country, exports annually about 400,000 arrobas (4,512 tons). The total quantity of yerba exported during the past year is estimated at about 9,024 tons, and the average price per arroba (25) was 11dols 50c paper (7s 8d)."

Correspondence

To the Editor.

TEA CULTIVATION IN SOUTH CAROLINA,
U.S., AND THE PROSPECT OF A
PROTECTION TEA DUTY.

Summerville, S.C., 13th August 1897.

DEAR SIR,—I have not received the July number of your excellent *Tropical Agriculturist*. I fear that it has quite gone to pieces in the mail. I recently sent you the Report on my Tea Farm by the Agent of the U.S. Department of Agriculture. The tea-duty must ultimately come and then the success of my work will be acknowledged.—Yours very truly,

CHARLES U. SHEPARD

[The Ceylon tea planters would not at all object to a moderate import duty by the United States Government on tea, as it would far more tend to discourage cheap and impure "Chinas" and "Japans," than the superior "Indias" and "Ceylons." There is no need, too, for Eastern planters to fear Mr. Shepard's little enterprise; for all he can do with his estate of 700 acres—of which, however, only a small area is under tea—with the available labour, will be to encourage tea-drinking habits among his neighbours and an appreciation especially, of really good pure tea, rather than to injure the import trade from Ceylon. The Report sent us is a very interesting one, and will be dealt with later: it is signed by Mr. 'Wm. Saunders"—the same worthy officer of the Agricultural Department at Washington who showed us over the offices and gardens during our visit in 1884, and who was specially proud of his solitary tea bush flourishing in the open air (at Washington.) We need scarcely say Mr. Shepard had not then begun tea planting or we should certainly have visited his garden at Pinehurst when we passed through South Carolina.—*Ed. T.A.*]

"GAPES" IN CHICKENS: A REMEDY
WANTED.

Sept. 8.

DEAR SIR,—I shall feel greatly obliged if either you or one of your many readers could give me a cure for "gapes" in young chickens I have lost a number of quite young chickens, about a month old from this. I should be most glad to know the cause and cure.—Yours faithfully,

"AMATEUR."

[An experienced Head Servant advises:—"Mix saffron and sulphur well together and rub thoroughly about the head," &c.—*Ed. T.A.*]

COCONUTS AND COPRA.

DEAR SIR,—The question whether it is wiser to sell coconuts or to convert them into copra does not offer the same difficulties as beset consideration of the advantages and disadvantages of the sale of tea locally and of shipment to England. For one thing, the fluctuations in exchange do not enter into the calculation, and then the rise or fall in the price of the article between the shipment and the date of the London sale, is excluded. Whatever millowners may have done when the Desiccating industry was in its infancy, they now recognise the fact that the

price of oil is the chief factor in determining the price of copra, and through it of nuts; and they regulate their offers for nuts accordingly. Not only so, but they discount the advantage they offer of quicker returns to the extent of fixing prices which have induced proprietors who are in no urgent need of cash to convert their nuts into copra, though the Desiccating mills are nearer to them than the oil mills; while needy holders have preferred to give the nuts they had unwisely carted to the mills without prior arrangement, at a loss, rather than carry them back for conversion into copra.

It is for these reasons I said in a few lines I sent you last week that estates at a distance from Colombo should certainly send down copra to Colombo rather than nuts. Of course, I mean, as a rule, and under present circumstances when the supply of nuts is ample for all needs—for the slack demand for oil and also for Desiccating mills working full time. If the supply fall rather short of the demand, or is only just equal to it, competition may disturb the fine calculation in prices which is now practised and which may yet induce me to convert my crops into copra though I am not far from Colombo, though I have generally preferred to sell nuts, and though I have benefited more from the sale of nuts than of copra, and though, like a burnt child, I dread fire. When distant estates are requisitioned for nuts, I rejoice, as I know they are getting to be scarce in, and

NEAR COLOMBO.

CASTOR OIL AND SUNFLOWER OIL.

Sherwood, Haputale, Sept. 13, 1897.

DEAR SIR,—I see there is an article in your *T. A.* magazine for August on the cultivation of castor oil and sunflower seed for their oils. Could not both these be grown to advantage in this island where they abound in the wild state? Is there any difficulty in extracting the oils for commerce?—I am, sir, yours sincerely,

PLANTER.

[We do not know that any systematic attempt has ever been made to extract the above oils in Ceylon; but the natives in the case of castor oil prepare a good deal for their own use after a primitive fashion, and we do not see why there should not be success in a big experiment; the native cheeku could, we think, be utilized for the expressing of castor oil.—Cultivation of both is a simple matter, though good or manured soil would be required.—*Ed. T.A.*]

TEA PREPARATION AND MACHINERY.

Central Province, Sept. 18.

DEAR SIR,—You ask the opinion of experienced Factory Managers in Ceylon on "Engineer's" letter of 4th Sept. in *Indian Planters' Gazette* on his remark: "a properly equipped withering-house should turn out the leaf at a given hour, let it be wet or dry." No doubt, that is the point to aim at; but there are precious few factories in Ceylon any more than in India that can meet this requirement. There is precious little control over the withering and that is why there is so much Sunday work. With reference to this same letter I should like to know "how many Ceylon planters have got Jackson's Rapids or Brown's Triple-action Rollers with their tops off and 2 feet added to depth of box and fitted up with circular battens?" Davidson's Roller meets this requirement to have leaf beautifully rolled and still keep leaf quite cool.—Yours truly,

ESTATE TROTTER.

TEA PREPARATION—OVER-FIRING.

Dimbulla, Sept. 27.

DEAR SIR,—Replying to the letter from “Indian Planter” there is no doubt that a large quality of tea goes into the market that is over-fired, although it has no taint of burning. This, I think, most often arises from too long final firing at a low temperature, until the flavour is baked out of the tea.

I get the best results from final firing at 220° in a Desiccator, using one chamber only, and spreading the tea half-an-inch thick on the trays. When the tea is slightly heated the odour is rather unpleasant than otherwise, but when hot, all flavoury tea gives off a fragrant aroma; as soon as this begins I think it is time to stop.—I am, your faithfully,
5,000 FEET.

REFIRING TEA: A QUERY FOR A
“PUBLIC-SPIRITED CEYLON PLANTER”
IN A HIGH DISTRICT.

SIR,—On an estate at a high elevation where delicacy of flavour is the chief desideratum we find that in re-firing the tea for packing, there is a decided loss of flavour. More strength perhaps, but less flavour is the result of re-firing for packing. Will any benevolent, public-spirited planter who has had experience with high-grown teas kindly offer any suggestions regarding the best temperature, length of time in drier, and thickness of leaf upon the drawers, which have been found to give the best results? I see the suggestion has been made *not* to re-fire for packing and doubtless if the binning of teas could always be avoided it would be very desirable to do this, but where one is obliged to bin the tea for a month or so surely, softness would be the result if the tea was not re-fired.—Yours faithfully,
INDIAN PLANTER.

CEYLON TEA IN RUSSIA.

Kandy, 27th Sept., 1897.

SIR,—I enclose letter received from Mr. Rogivue, regarding his work in Russia, in pushing, advertising and making known Ceylon tea.—I am, Sir, yours faithfully,
A. PHILIP.

Maroseika-House, Lebedieff,
Moscow, 21st August, 2nd Sept., 1897.

A. Philip, Esq., Secretary to the “Thirty Committee”
Kandy (Ceylon.)

DEAR SIR,—On my return from abroad, I find your letter of the 23rd July covering letter of credit No. 35/18 of the National Bank of India Limited, dated 22nd July 1897, for £st.500. (Five hundred pounds sterling) in my favour, to be used by me for the advertising of Ceylon tea in Russia. I thank you for this remittance and take due note of the resolutions passed by your Committee at one of their recent meetings, of which you send me a copy.

I also note that Mr. Thos. North Christie has been appointed by your Committee to visit Russia during the current year. I shall have great pleasure to see here this gentleman and will make it my duty to give him every information regarding the work done, the money spent and the steps to be taken in future for the furtherance of Ceylon interests in this country.

When I was the last month in London, I have been pleased to attend a very interesting meeting of the “Ceylon Association,” when I gave to the gentlemen present a short illustration of the work I have done during the past months of this year. The progress, I am glad to say are going steadily and the quantity of Ceylon tea imported in Russia is increasing visibly.

Many merchants are selling it *pure*, the consumption is now on a much larger scale and the quantity used for blending with China tea is getting rather important.

I also notice that *direct* Export from Ceylon to Russia has—in the six months past—from 1st January to 30th June 1897) increased of 10,600 lb. over the corresponding six months in 1896.—I am, dear sirs, yours faithfully,
M. ROGIVUE,

TREE PLANTING IN CEYLON :
AUSTRALIAN TREES BY AN AUSTRALIAN
FORESTER.

DEAR SIR,—Being on a short visit to your beautiful island and having during that time found my way to “Kandy” and to “Nuwara Eliya,” etc., and having observed the nature of the soil and climate, and its accompanying conditions, I was much struck with what I judged to be the fitness of the country for the extension and profitable growth of our Australian Red cedar (*Cedrela Australis*), so it occurred to me that this valuable and very light and easily worked handsome furniture timber might well be made to take the place here of a great deal that is now next to valueless, or only made use of for shade purposes amongst the cacao plantations, etc., in what was originally the jungle forests in and about Kandy, and other kindred places. In Australia this tree, so long and much sought after for its timber, is now becoming very scarce, and is besides more or less subject to the ravages of the ova of a moth which deposits her eggs in the young shoots when as they mature in the grub form, they eat the young tender germinating leaves and eventually work their way down into the pith of the young wood and, in this way, often do considerable damage. In this country I think it is highly probable that it would not have this pest to contend with, and as it is a quick-growing tree, and of large size (up to 20ft. in circumference) it might perhaps be introduced and cultivated to the greatest advantage, more especially on the hill slopes under the partial protection of other trees. That the Australian trees will thrive *well*, *now* you have abundant proof in the thousands of silky oaks (*Grevillea robusta*) to be seen on the tea plantations everywhere between “Kandy” and “Nuwara Eliya,” besides eucalypts; also some of our acacias, *A. decurrens*, and *A. melanoxylon*, at the last mentioned place, where I have rarely seen their growth equalled in their native soil and habitat, nor have I seen a more vigorous and promising growth than is to be observed in the other trees mentioned, even in their native Australia, unless I except *E. Globulus* which might do better, but here I would remark that in some places under my observation, unless thinned out at an earlier stage of their growth, some of them are planted a great deal too close together. Of our eucalypts in N. S. W. I would recommend a trial of our Blackbatt, *E. pilularis*, which is a very quick straight-growing tree whose timber is fissile, and lasting when mature.

There is one thing in which I may compliment the tea planters of Ceylon: in the enterprise they have shown in their tree planting; also the administration of Ceylon in their system of Conservation of Forests, both of which have put us to shame in N. S. Wales, where these matters are treated with stoical and ignorant indifference, both by its people and Government.

AUGUSTUS RUDDER,

N. B.—I have been a continuous resident in N.-S. Wales for over 60 years, and for 12 years in its Forest Department.—A. R.

P. S.—The timber of *Grevillea robusta* in N. S. W. is considered our best for the staves of casks as it is tough, does not warp, nor does it shrink much, nor impart any bad flavour to wine or butter stored in it. Our only regret in respect to it is, that it is now very scarce, indeed while we are now losing some of our best timbers, and fodder plants, other countries, more alive to their importance than ourselves, are getting the benefit of them. In N. S. W. the proportion of forest that has been conserved is little more than 2½ per cent of the whole and even this wretched provision is constantly liable to curtailment under political pressure from outside influences, and very bad Timber Regulations under an uninformed Administration of Forestry.—A. R.

TREE-GROWING IN CEYLON.

Abbotsford, Nannuya, Sept. 30.

DEAR SIR,—There is neither *Eucalyptus ptilularis* nor *Cedrela Australis* on Abbotsford; but there are specimens of the former on Carlakeck in the near neighbourhood. It is a magnificent tree and nothing better could be used in forest clearings, but amongst tea it is objectionable, as it is one of the eucalypts which exudes any amount of tarry gum which tea dislikes. *Cedrela Australis*, I presume, is allied to the *Cedrela Toona*, etc., which have been tried extensively here.

The *C. Australis* evidently suffers from insect pests in the same way as the White Toon, and I should therefore say leave it severely alone in its native habitat.—Yours faithfully, F.

HOW TO ECONOMISE THE AVAILABLE LABOUR SUPPLY.

SIR,—From afar I venture to give you my ideas on some of these points: but will only touch on such of your questions as I can tackle with full personal knowledge.

To begin with, let me bracket questions 2 and 8. Let your field S. D.'s have a pony each, especially on large estates, and more especially in the lowcountry. It is a long morning from 6 till 11, and after 8 o'clock many a youngster feels slack and limp, especially where he has to cover long distances over rough ground from point to point, not to mention that a pony will save much time otherwise wasted in weary trudging, and will allow considerably more attention to be given to field supervision. I am satisfied that more time behind the gangs would result in more work being got out of the coolies; and a man fresh from the saddle would have more energy and could impart more of the same to his coolies, than one pumped out by a steep short cut; languidly dragging one foot after the other, and only wishing it was time to get back to the bungalow. I have vivid recollections of my S. D. days when I was not allowed to use the road if there was a short-cut; and I know of one man who was told by the doctor that he had injured his heart permanently by "busting it" up *Koorka pāthics*. There used to be an idea that a man who rode to his work was lazy. The sooner this is put aside, the better.

4. The cleaner the estate the cheaper the work; and I never met a man who "believed in weeds" but he was short-handed. As soon as such an

one has sufficient labour he will unblushingly tell you that his estate has always been clean and that he never did believe in weeds!—and he is invariably stronger on the enormity of a dirty estate than the man who has been habitually clear.

5. Less frequent weeding would certainly end in disaster: and selected weeding is not possible in practice. I have known it tried: but the inevitable tares came up with the wheat, and the last state of that man was worse than the first.

6. Wheat and tares again.

7. Drainage might be much improved by renovation pits between the existing drains. These conserve much soil which is otherwise carried away; and if made big enough, could be filled in with prunings, the prunings, of course, being covered, and fresh pits opened. These cannot be too many nor too big. I prefer them in shape of a trough two feet deep and long enough to cover two trees. They should, of course, be diagonally one below the other, so as to overlap each other over the whole field, thus reducing the loss by wash to a minimum. They are risky on steep lands with heavy rainfall; as an overflow from such pits would cause more damage than bursting drains.

9. Gardens by all means. If they are well kept, you know that your coolies intend to remain. But no extra perquisites. One great cause of the labour trouble is that Ramasamy is too rich already. No Asiatic can stand prosperity. What percentage of coolies had plain rice and chillies brought out to the field twenty years ago? And how many have three meals a day of good curry and rice today? Most appetising is an occasional snuff from their breakfast in the fields. Further perquisites or presents make Ramasamy think himself indispensable, and as soon as that idea gets into his head, he is useless.

10. *Estate boutiques and monthly payments are excellent*—but the present custom of advances and payment of coolies puts the system, with its control of boutique debts, out of the region of practical politics.

WILD MAN OF THE WOODS.

PARAGUAYAN TEA.—In a report to the Foreign Office, quoted in the *Board of Trade Journal* H. M. Consul at Villa Asuncion states that *Yerba-maté* or Paraguayan tea, is the most valuable article of export from that place. There are two classes sold, but it is only in the manner of preparation that they differ. The kind known as "Mboroviré" is merely dried over a furnace, and then beaten into small pieces with sticks. The "Molda" goes through the same process, but it is afterwards ground in a mill. The export duty on the former was increased in 1895 from 30 c. paper to 10 c. gold, and on the latter from 25 c. paper to 9 c. gold per 10 kilos. The revenue derived from this source in 1895 amounted to 471,668 dols. (£16,845). The *yerba* forests, called *yerbales*, were formerly the property of the State, but most of them have been sold, and are now in the hands of a few capitalists and companies. The Industrial Paraguaya Company, which owns about half the *yerbales* known to exist in the country, exports annually about 400,000 arrobas (4,512, tons). The total quantity of *yerba* exported during the past year is estimated at about 9,024 tons, and the average price per arroba (25 lb.) was 11 dols. 50 c. paper (7s 8d.).—*Journal of the Society of Arts*, Sept. 17.

"HOW TO ECONOMISE THE AVAILABLE LABOUR SUPPLY ON OUR TEA PLANTATIONS."

(Letters Continued.)

No. XLII.—HIGH DISTRICT.

1. Wire shoots of great advantage. The damage to leaf can be minimised.
2. Aërial tramways.
3. Average estates are too steep; and curves awkward.
4. Not, when well drained beforehand.
5. Not on my own estates.
6. Have not tried. The experiment would be useful.
7. Have no experience of cuscus. Might not the roots prove a nuisance in the soil?
8. ———
9. Time and half for night work in factories. Keep the lines clean and in good repair. They usually have gardens enough. Few care much for them.
10. A rice store and one boutique are good.
11. Liquor shops (having usually very bad liquor) are a curse to the coolies. D. K.

No. XLIII.—UVA.

1. I have worked wire shoots for transporting leaf, and consider them a great labour-saving appliances. If terminals are properly arranged, no damage will be done to leaf.
2. On most estates labour might be economized by construction of light cart roads, and working single bullock carts to take leaf to end of shoots, firewood, &c.
3. Tramways in my opinion can only be profitably utilized in very large concerns. On ordinary estates, traffic would not pay cost.
4. I certainly do not consider weeding has ever been overdone in Ceylon, and weeds when not regularly taken out, become both expensive and troublesome.
5. I certainly would not advise less frequent weeding, as a means of saving labour. In the coffee days it was tried with disastrous results.
6. I have never tried the experiment and would prefer seeing some one else do so.
7. I scarcely think cuscus grass or anything else would have much effect in the retention of the soil, when the rainfall registered in a couple of hours as 7 inches, and this is no uncommon occurrence in many parts of the island.
8. ———
9. Coolies are very fond of their gardens. All the same they are a doubtful advantage. The lazy coolies prefer staying in the lines to coming to work on the chance of being able to steal his neighbour's produce. The working cooly often remains at home to watch his garden produce; and often as not gardens are only nurseries for weeds.
10. No, decidedly not. It would only multiply the coolies' borrowing powers, which are already extensive enough.
11. Not with liquor shops licensed, but illegal sale of arrack is carried on to a great extent in the villages, where produce is taken in barter, both tea and coffee find their way to these dens, and small chance of catching the thieves or getting a conviction when they are caught. J. B.

No. XLIV.—HIGH DISTRICT.

1. No experience of their working, but I think they might with advantage be used on most estates. They are said to damage tea leaf, but it would get as much damage during long transport in bags on coolies' heads.
2. Small tramways in factories and withering houses save a great deal of labour, and, if more automatic working of machines could be thought out and applied by engineers, tea house labour would

be saved and the work of the tea-house would be more satisfactory.

3. Only on estates with a favourable lay of land; not on the majority of upcountry estates.

4. Not hand weeding, but carandi weeding is certainly overdone, and it is very difficult to prevent it.

5. Less frequent weeding would result in a continual increase of weeds, and more expense or labour; a three weekly weeding would in the end take less labour. Mosses, and small ferns, &c. can be left with advantage.

6. No. Digging on the average estate, with the ordinary system of drainage, would probably result in the loss of a great deal of soil.

7. Not very satisfactory. I have seen good results in the way of retaining the soil from planting hedges of tea on the upper banks of roads and drains.

8. By giving tasks as much as possible, and paying extra for extra work done over and above the ordinary task, especially in plucking.

9. Coolies appreciate the privilege of having space given to them for vegetable gardens and of keeping cattle, where there is grazing land. Where land is reserved for gardens round each set of lines, coolies are more likely to be contented.

10. It is always an advantage to have boutiques on or near an estate, and coolies will work more regularly in this case than if they have to go a long distance for supplies, as they are then more likely to want a day off work.

11. Yes; and I find liquor shops and arrack cantens most demoralising to coolies. The fewer liquor shops in a district, the better for all concerned, for there is nothing so damaging to the efficiency of a labour force as the close proximity of a liquor shop. J.

REVIEW OF LETTERS XXXVI TO XLIV,

The nine letters under notice, share many of the distinguishing features of those which preceded them, especially in variety and vigour; and they cover more space than the batch of letters we last reviewed. "A. F. C.," from the low-country, has avoided the mistake of attempting to find an answer to each question in a word or two; and his deliverance on wire shoots is specially interesting, as his experience, based on the erection and working of several of them, is entirely in their favour. One in six is a reasonable all-round gradient and by no means too steep, though he has set up and worked shoots as flat as one in 15, but these require runners of large diameter to facilitate work. He has found that leaf is not damaged if carefully packed and the loads are not too heavy—say over 56 lb. This is also the experience of "Hantana" from a medium district, who is convinced that they save a lot of labour, that in many cases they pay themselves, and that they might be much more largely used. "W. B. J." from a high district, has no experience of shoots, except for firewood; but he is contemplating an overhead wire tramway for the transport of leaf from several estates to the central factory, and believes this is just the direction in which time and labour might be saved, where both are of importance. "A. V. R." also from a high district, like the two correspondents who follow him, has a blank against wire-tramways; but he is a believer in shoots and finds they do not damage leaf when properly worked at the receiving end. That, too, is the experience of "T. C. H." of the Kandy district, who has used shoots for the last five years in sending down leaf to the factory, with a good buffer of grass at the lower end which prevents any appreciable damage to the leaf. "S." from a Southern district, on the other

hand, has been unable to prevent some damage to leaf and would prefer not to shoot leaf, except where there would be a great saving of labour. We fancy the gradient and the weight of the loads explain this difference of opinion; for we find both "D.K." from a high district and "J.B." from Uva uniting in their testimony in favour of shoots, as of great advantage in saving labour without damage to leaf if the terminals are properly arranged; while "J." also from a high district, though he has not worked shoots, sees how they must save labour, and how the damage to leaf need not be greater than during long transport. He also appreciates small tramways in factories and withering houses; but considers out-door tramways unsuited to the majority of upcountry estates; and that opinion is shared in by all the writers whose letters are under notice, including "A.F.C." who,—although he has laid three miles of a two feet gage and has practical experience of tramways,—regards them as unsuited to most estates. There is nothing in his view—and most of the letters we have noticed comprise that view—to touch the cart road and bullock baidy for economy and serviceableness, and there is the further advantage of their being thoroughly understood by the native.

On the question of weeds and wash too, "A.F.C." writes with welcome freshness, and without being afraid of differing from other danters. He has no doubt that weeding is overdone; but the difficulty of deciding what special weeds peculiar to each locality should be left, and the impossibility of following the Indian plan of leaving everything to grow and then digging it all in, without the risk of having all the surface soil washed off, have reconciled people to the present system. Moss, as more than one previous writer hinted, has a tendency to sour the soil by excluding light and air; but on Labnkella estate our friend cultivated a creeping grass which prevented wash admirably; although he fears his successors may have regarded the experiment as "rot." He prefers guinea-grass to cuscus, as serving for fodder, while protecting the edges of drains. "Hantana" and "W.B.J." do not believe there is over-weeding, though the mamoty and scraper are objected to. Grevilleas are recommended, as their leaves prevent wash, and the wood is useful for fuel; but the growth of a crop to be dug in is an experiment which "Hantana" as well as "J.B." would wish some one else to try; while "W. B. J." refers to experiments with Scotch thistle which did not succeed, though he fails to see what the benefit would have been if the weeds had been replaced by the thistle! In fact there seems to be a consensus of opinion against digging in on steep lands, and a prejudice against a second crop on land of every description. Cuscus, about which some writers seem doubtful, does not, so far as we know, spread in a way to damage tea, while it can be easily thinned if it shows too great a tendency to spread. Tea hedges certainly strike one as a good idea; but whatever precaution and preventives be adopted against wash, there is nothing so effective as a careful system of drainage at the outset—shallow drains, of gentle gradient, not too far apart and with traps at intervals, for they can catch something more than silt, at any rate during average showers. It is noteworthy that from one planter comes the suggestion of effective supervision as one of the most potent means of saving labour; and from another the regular enforcement of tasks with

extra pay for extra work. Frequent absences from the estate, even for such pleasant recreations as most districts provide, and which, in moderation, would be most unreasonable to condemn,—can scarcely help towards effective supervision or the exaction of a good day's work for a day's pay; and if "master" takes it easy, Ramaswamy has too much of human nature in him not to follow the comfortable example. In this connection "A. F. C." raises the important question of the sufficiency of the cooly's pay, and whether the extravagant advances now in vogue, most of which are irrecoverable, are not an undesirable way of giving the cooly a higher rate than appears in the check roll. The discussion of higher wages is scarcely opportune in the face of dwindling profits; but how can we be sure that a higher rate of wages—even if adopted—would give the quietus to the injurious system of advances? While gardens commend themselves to most employers as a great attraction to coolies, it is gratifying to find that several of our correspondents give prominence to firm, just, yet kind treatment, with an occasional jocular remark, as the best way to attract the cooly to, and make him respect, his durai. The multiplication of boutiques is generally regarded as a mistake, as also would be the absolute prohibition of "a drop," seeing that it would be impossible to enforce such prohibition. It is quite evident that as regards the relations of master and servant, cooly and the durai must be in touch if they are to work to the best advantage of both, and this is just what so many experienced men say the young planters of the present day—with notable exceptions of course—fail to realize, not qualifying in the cooly language as they ought, nor in attention to cooly complaints, quarrels and little wants, even to the extent of an occasional jocular remark!

(Letters Continued.)
NO. XLV.—KOTMALE.

1. None.
- 4.5. Weeding.—The existing system of weeding cannot well be beaten if carefully done with the minimum of scraping and moss and soil undisturbed in order to get a cover over the ground. Less frequent weeding would mean vigorous scraping, loss of soil and ere long more expensive weeding. It has already been proved that two-monthly or three-monthly weeding is more costly in labour per acre per annum than monthly weeding.
6. On weedy estates, rows of grass might with advantage be planted above drains, but on clean estates there is very little wash: hence these are unnecessary.
9. Labour.—Out of a total force of 764 working coolies and children, I find 175 were born on the estate. Some have never been to India and it has occurred to me that estates would have a better chance of retaining the old coolies and in a great measure stop the constant changing of estates by coolies if all estates were to adopt some system of an annual bonus to both adults and children born and resident on the estate, say at Tivali or Thai Pongal. I have been thinking out a scheme for some time, but have not yet decided upon the best means of doing it. A coat or cloth to each cooly would not amount to much and be money well spent. A. F. S.

NO. XLVI.—NORTHERN DISTRICT.

1. —
2. —
3. —
4. There is weeding and weeding! Weeding has been vastly overdone by scrapers and mamoties. Hand weeding can scarcely be overdone.
5. With scapers, weeds cannot be easily "selected." Mosses and hard ferns are not eradicated on my places, unless the ferns become too luxuriant.

I would not advise such experiments unless the land is flat.

6. No, and would not advise it.

7. Yes—in the circumstances No—the cuscus scheme is not practicable on a large scale. The rows would have to be moved every year or so.

8. ———

9. No. I always allow gardens up to reasonable limits.

10. No. Prices in these small boutiques are generally so high that a working cooly will never go to them if he can get to a larger village. They are besides admirably adapted to facilitate the cooly's getting into debt, and illicit sale of liquor.

11. No. But there is plenty of illicit selling. I scarcely think anything short of abolition of liquor shops within 25 miles of an estate would stop drinking and even that would only do so partially. The vicinity of villages with toddy trees also must not be overlooked.

The labour difficulty began with altered conditions of superintendence, assisted by the Medical Aid Ordinance, and its remedy is probably to be found in superintendents' hands taken generally. The cooly is pretty much what we have made him or allowed him to become. W.

NO. XLVII.—HIGH DISTRICT.

1. I have not much practical experience of wire shoots as regards leaf transport, but they must injure it to a certain extent.

2. A question impossible to answer without knowing cost of tramway. But on certain estates it would free a larger proportion of coolies for plucking purposes.

4. Weeding is not overdone in Ceylon. The best form of weeding, if it could be carried out, would be once in three weeks. At any rate in wet weather.

5. This applies to 5 or 6.

7. The present drainage system, I don't think, can be much improved upon.

9. *Coolies*.—A certain amount of ground should be allowed round all lines for gardening purposes. Attention should be given to the water supply. Coolies greatly appreciate a supply of pure water, (which can only be done by spouting from the source) laid on to the lines.

10. A bazaar supported by the estate (at fixed rates as far as possible) is an excellent thing, but coolies would obtain from this all they could afford to pay cash for and would then probably run into debt in the bazaar outside. What in my opinion would be the best check against coolies running into debt in the bazaars would be a law making advances from the estate to the cooly a first claim over any other debts. Chetties rather would not then be so ready to accept Kanganies' promissory notes, which are the ruin of many a labour force. C.

NO. XLVIII.—MID DISTRICT.

(1) Yes, certainly. No; on steep gradients shunts could be used to obviate any damage.

(2) In the field, plucking shears; but I do not recommend them. Factories are as a rule, so well equipped now with labour-saving machinery that but little, if any, improvement can be made.

(3) No, but I think that Tavalam bullocks could be more freely used for transport of manure, tea boxes etc.

(4) Yes, most decidedly. Present system seems to me more for appearance than for any advantage derived therefrom.

(5) I should certainly advise a less frequent weeding, say once in six weeks, also selected weeding, taking care to keep the tea trees clear of mosses etc. 6 inches round the stems.

(6) No. Yes.

(7) No. Waterholing might be advantageous. The rows of cuscus grass on a neighbouring estate are certainly deterrents to washing down of soil.

(8) I can suggest nothing further.

(9) Gardens round lines are general. In my opinion as much ground should be given to coolies as is available and can be spared for the purpose.

(10) Yes, but coolies will go to the principal bazaars in their neighbourhood to learn the news and to meet friends and relatives from other estates.

(11) The liquorshop in this neighbourhood (which is luckily somewhat distant) gives no trouble, but there is a considerable traffic in illicit toddy.—No, as it would only lead to further illicit sales (and of adulterated liquor.)

“S. E.”

NO. XLIX.—HIGH DISTRICT.

(1) *Wire Shoots*.—These are invaluable when ground is suitable, but gradients in hilly districts are often too steep for effective working and the converse holds true in the lowcountry. Intermediate ridges are the chief obstacle to their general employment.

(2) *Labour-saving Appliances*.—Except sifters and automatic driers, labour-saving appliances are of little use in a factory. A certain staff is required and labour-saving appliances reduce the hours of work rather than the number of men employed.

(3) Not in upcountry districts—there are about 10 miles of roads to 300 acres—at least 3 miles of road (Tram) would be needed to transport say 300 tons of green leaf per annum.

(4) Clean weeding may be overdone, but I do not think a dirty estate would last longer in bearing or give more crop or cost less than a clean one.

(5) Less frequent weeding would not save labour in the long run. Moss and selaginellas are hurtful to tea owing to the damp they engender. A cooly is not a botanist and it would be difficult to get him to discriminate between injurious and beneficial weeds, if the latter exist.

(6) No! I should be willing to try the experiment if seed were available.

(7) A tea hedge above each road and drain seems to me the best conservator of soil; if pruned low, it does not interfere with passage of workers and gives a good crop of leaf.

(8) It is evident that one must have coolies sufficient to pluck the maximum crop of the largest month and to manufacture it. The difficulty is not to save labour, but to find work for it in the slack months when sufficient for high pressure of crop.

(9) Coolies have as a rule more garden ground than they work. The gardening cooly very often does not work and simply squats on the estate occupying line room, keeping others away from the estate. There are exceptions to this rule.

(10) Small boutiques for each estate would keep down opportunities for crimping, but there are objections to them as leading to inferior supplies of certain articles.

(11) Liquor shops could not be too much reduced in number, provided that illicit sales were kept down. Quality of liquor should be rigidly seen to. R.

NO. L.—UVA.

(1) Yes, they might be more freely used. They do not damage tea leaf if laid at an easy gradient.

(2) Tramways in factories. Endless wire ropes, where the weight of down load brings an upload.

(3) Certainly wherever the easy gradient of road will admit.

(4) No. Kanganies must have a *quid-pro-quo* if weeding contracts be taken from them. (R100 a cooly!)

(5) If I resort to this, it will be solely due to shortness of labour.

(6) No. I cannot write from any experience of this.

(7) Yes. The closer the drainage, the less soil is carried away.

(8) A contented labor force and good rice.

(9) No. I don't think it is a situation of the cooly's lines has a good deal to do with this question.

(10) I would certainly.

(11) No. I consider them nearly a necessity, though I visit with severity any laborer who forgets himself in this respect.

No. LI.—MEDIUM DISTRICT.

(1) I consider wire shoots might be more used than at present. They do not damage the leaf. Wire shoots are most useful when they can also be made use of in manuring.

(2) A wire shoot from cattle shed, wire at the far end which can be moved from one part to another of the estate.

(3) I do not think so.

(4) I do not think *hand* weeding could ever be overdone, but I have noticed great damage being done by the use of mamoties and carandies.

(5) No. Not if hand weeding is done.

(6) No. I think not.

(7) The present system of drainage is satisfactory, and I am of opinion that nothing can be done to improve on it that would pay for the extra outlay.

(8) By paying cash for anything over a certain number of pounds. But the coolies require to be looked after and always paid by the Manager himself. There is no doubt an estate can be worked with two-thirds of the coolies if extra cash is paid and it is also cheaper.

(9) Yes, any cooly that wishes a garden can generally have one. A cooly allowed to look after all the coolies' cattle when out at grass.

(10) No.

(11) No. Great trouble is caused by the unlawful sale of fermented toddy by villagers.

G. C.

No. LII.—MEDIUM DISTRICT.

(1) Planters as a rule do not let slip opportunities for adopting labour-saving appliances. Wire shoots do not necessarily damage leaf.

(2) Wire tramways are the most paying appliances I know.

(3) The tramways you speak of are, I presume, small railways. They are not to be recommended as an estate appliance, but are possible as a district appliance.

(4) Never! Our contract system is our *grandest* labour-saving appliance. Indian men envy and wonder.

(5) See answer to No. 4.

(6) It would add to our labour troubles; though as a manurial agent, it would do good. On the score of labour, I deem the experiment inadvisable.

(7) Our drainage system has been often carried too far, removing too much moisture and thus checking the flush in dry weather. The rows of cuscus grass would only be a very partial remedy for wash.

(8) The only important direction in which labour might be saved is by the abandoning of unprofitable fields.

(9) Nothing but fairness and justice. "Suaviter in modo, fortiter in re." The velvet glove covering the iron hand.

(10) Each estate should have its own boutique run by the estate or a kangani; and all kaddie-keepers and chetties should be deprived of the power to give credit to our coolies by an ordinance.

(11) Rather! No liquor shops if possible, and no liquor on credit. Government *must* step in and protect our coolies as soldiers are protected; and we must be prepared to issue supplies ourselves to our coolies. In Australia, I believe, publicans can only recover a certain limit from all bushmen. So a law should be passed fixing say R12 per annum as the maximum legal credit or debt that can be recovered from a coolie.

"1897."

No. LIII.—HIGH DISTRICT.

(1) Wire shoots are certainly a great saving where roads are steep for transport and factories distant. Leaf I have never found damaged.

(2) Leaf carts for transport where roads are available. Machine or hand-packers in factories if cheaper would probably be more used.

(3) There is too much horse traffic on most estate roads to allow of tramways being used. I doubt the saving even if practicable.

(4) The average estate weeding (i.e. *scraping*) is overdone. Land weeded carefully by hand or small stick is always clean and consequently take less labour. Scraping and scrapers are generally winked at.

(5) Moss on banks of drains and roads should be carefully left untouched. It keeps the soil up and does no harm.

(6) ———

(7) Holes cut in alternate rows are being tried on some estates to catch wash and soil, and are proving effective.

(8) A question most of us would like to know. Energy and a European S.D. means more work from the coolies and a smaller force required.

(9) Gardens are generally allowed, but very few contain anything worth growing. On estates where cattle and goats, etc., are allowed, the coolies seem content.

(10) The less bazaars the better. Most estate coolies deal near their rice depôts where they go on Sundays.

(11) Liquor shops do not themselves directly do harm, but the retailing of arrack in the lines means several coolies absent from work.

H. H.

REVIEW OF LETTERS NOS. XLV TO LIII.

The nine letters under notice are as full of interest and variety as their predecessors. "A.F.S." and "W." from a northern district are silent on wire-shoots and tramways; while "C." from a high district, who confesses he has not much practical experience of shoots in the transport of leaf, inclines to the view that they must injure leaf to some extent. As one ounce of fact is to be preferred to a ton of theory, "C." will be pleased to find considerably more than an ounce in the letters we have already reviewed, as also in many which follow his own welcome, if cautious, contribution. Thus "S.E." of a mid-district is emphatically in favour of shoots, and says that on steep gradients "shunts obviate any damage." "R." from a high district, regards them as invaluable when ground is suitable, though some places upcountry may be too steep, just as in the lowcountry the fall may be too flat for effective working; but the chief obstacle to their more general employment is the intervention of ridges. "D." from Uva, thinks shoots might be more freely used, as they do not damage leaf if they are laid at an easy gradient. "G.C." from a medium district, endorses this view; and so does "1897," who, however, considers wire tramways the most paying appliances in his experience; while "H.H." goes further, and declares he has never found leaf damaged by the use of shoots, which he holds to be a great saving of labour where the roads are steep and factories distant. And yet, he does not disdain leaf carts, where roads are available. Ground tramways continue to find little favour with our correspondents, owing to their initial cost—though for district, as distinguished from estate, purposes, they would be welcomed in many directions. Among the other labour-saving appliances which are recommended, are machine or hand-packers in factories, if their cost could be lessened; wire-shoots from cattle-sheds to be shifted to suitable points at the other end; tramways in factories; endless wire ropes, where the weight of a down-load brings an up-load; the planters' old friend the tavalam bullock; while one writer regards the contract system—the envy and wonder, he says, of India—as the "grandest labour-saving appliance" of the country, and the most economical means of weeding; and yet another thinks that cash for extra work beyond the task, would enable an

estate to dispense with one-third of its labour force. This, surely, is a matter that needs investigation; for although the dictum may support the view of more than one old planter, that the average of work at the present day is far lower than it used to be, it would indicate a way out of the difficulty of enforcing a full task, and facilitate the recovery of advances. The cooly who earns his extras will have less objection to deductions on account of advances than the man who is demoralized into idleness by the weight of advances he can never hope to liquidate.

On the question of Weeding, there is the same conservative love of the existing system which earlier letters disclosed, qualified by protests against the excessive use of karandi and mamoti. "A. F. S." thinks "the present system cannot be beaten;" but he would leave moss and soil undisturbed as far as practicable, and he would grow grass above drains on weedy estates, as there is very little wash on clean estates! "W" admonishes us that there is weeding and weeding, and that there has been overdoing only where scrapers and mamoties are in use. Hand-weeding cannot be overdone; and he leaves mosses and hard ferns alone, unless where the latter becomes too luxuriant. "C." is emphatic that weeding is not overdone in Ceylon, and he holds that the present system of drainage cannot be much improved on. "R." does not think a dirty estate would last longer than a clean one, and he condemns mosses and selaginellas as hurtful to tea owing to the damp they engender, while, with the unbotanical cooly, selected weeding cannot be entertained. "D." is as emphatic as he is brief against any interference with the present system; for without weeding contracts, the kangani will expect R100 per cooly. So with "G. C.," "1897" and "H. H." who more or less reflect the opinions of the writers we have above-quoted. The only exception is "S. E." who is most decidedly of opinion that weeding is overdone, and that the present system seems to aim more at appearance than any real advantage from an agricultural point of view. He is in favour of less frequent weeding—say once in six weeks—and would enforce selected weeding, taking care to keep mosses away within six inches of the stem.

There is general satisfaction with the present system of drainage, with slight modifications, suggested, we fancy, by local circumstances. Cuscus has not many friends as a stop-wash, but it is not altogether shunned by those who have tried it, or have watched its effect on adjoining places. Though gardens are generally recognised as an attraction to coolies, and planters, where they can, allow them suitable plots, and also liberty to keep cattle and goats, we find very decided testimony from experienced and influential quarters that, what the cooly chiefly wants is fair-play—firmness combined with kindness, and a real interest in his poor soul and body. That was the secret of the *durais* of old; but, somehow, the modern master is, with commendable exceptions, either too busy or too keen on sport to cultivate the acquaintance of his labour force, and to make his men understand that he really cares for their welfare and is willing to listen to their grievances and remedy them, so far as he may. We should be glad to find the experience of "A.F.S." more common. Out of a total force of 764 working coolies and children, 175 or nearly one-fourth, were born on the estate, and a goodly number have never been to India! Similar results might, he thinks, be obtained

on other estates by occasional presents and bonuses. The suggestions are worth considering and trying. Boutiques and taverns call forth much diversity of opinion. Some favour estate boutiques as tying the cooly down to the spot; others regard it impossible to check the vagrancy of coolies in search of a bargain whereby even a cent may be saved on curry-stuffs, while an estate boutique is generally a handy receiver of stolen produce. Some would make Rainasami a teetotalter; others see the impracticability of enforcing total abstinence, however desirable, and welcome licensed taverns, as greatly to be preferred to the illicit sale of arrack.

(Letters Continued.)

NO. LIV.—MID-DISTRICT.

1. I consider wire shoots on estates, where suitable sites are to be found, a very great saving in transport of leaf. Where practicable, more should be used. They do well also for transport of fuel.
2. I fail to see why all final firing and packing should not be done in Colombo, all teas being sent down in special chests made for the purpose in good stout paper, so saving transport of all lead, nails, hoop-iron, etc. up to the estate.
3. I think not; besides, most estates require all their fuel for factory.
4. Nothing like clean weeding from the first. When tea covers the ground well and when weeding is done for a rupee per acre per mensem, I think, seeing our pluckers have to go over the ground every eight days, they can, at the higher altitudes, be made to keep down all weeds—when the kanganies would be well paid if they got 50 cents per acre *pro rata* on number of pluckers employed during the month, thus saving 50 cents per acre.
5. No, I would weed as above. Mosses and small ferns should be left as they do no harm, and all help to keep up soil and prevent wash; indeed with this in view, tea should be planted closer I should say two plants in each hole, say 18 inches apart. Land planted in this way will terrace itself, no matter how steep.
6. No, beyond growing grevilleas for fuel which do no real harm to the tea. I would do nothing in this line. The mulching of the ground by fall of leaves of this tree does a lot of good particularly in thin tea where there is a large percentage of vacancies.
7. I don't think we can improve our present system of draining. Drain as close as possible; but, try to have few leading drains, other than natural ravines, as possible as they always cut up terribly with our N.E. plumps. I don't believe in soil traps, the best soil is always washed away, leaving nothing but sand in the trap which is useless.
8. The best means of saving labour is to get a good S.D. or conductor and make him carry the pocket checkroll regularly, thereby keeping a lot of cents off the cost of the pound of tea. Allow a fair rate for each work and don't let it be exceeded.
9. Cooly gardens should always be encouraged; they are a sure sign of contentment. Few coolies, however, care to have them owing to the thieving that goes on.
10. Yes, every estate should have its own bazaar. They help to keep the coolies from wandering and from being cramped and save a lot of time lost by coolies, who should be at work, having to go for their supplies in some cases long distances.
11. Yes; the very curse of the low-caste natives. Government Agents should restrict them as much as possible in planting and all other districts.

OLD PLANTER.

NO. LV.—HIGH-DISTRICT.

1. I have had no experience in wire shoots, but have seen them working. They save labour, and might be used more than at present. Can't say whether they damage leaf or not.
2. Can't think of any except those generally known.

3. Tramways would be too costly, including their own cost and the sacrifice of a number of tea bushes.
4. I prefer the present system of monthly weeding to any other.

5. With the present system of manuring, mosses, etc., would scarcely get time to grow.

6. Answered in No. 4.

7. I think close draining on the present system the best. Can't give an opinion, on the effect of rows of cuscus grass planted above drains, having never seen them, or ever heard of the system being carried out before.

8. ?

9. There are gardens around all my lines, but very little grown in them except weeds. The only thing coolies seem to care about now is getting into debt. It leaves them no time for gardening.

10. I think the system would be a good one, but it is very difficult to get boutique-keepers to start in isolated places. They like clustering together in certain central spots.

11. I am not troubled much with drunkenness amongst coolies except at Teevali and Pongal.

T.

No. LVI.—LOWCOUNTRY.

1. Have only used shoots for firewood. They might be used a good deal in this district for short distances.

2. Narrow cart roads for half-carts might save a good deal of labour on large estates.

3. I fancy cost and upkeep would be too large.

4. Yes, but the *cheapest* way is to keep the land clear of weeds by monthly weeding and—

5. I do not think there would be saving of soil or labour by less frequent weeding. Selected weeding might do good.

6. No.

7. I have done a little terracing above roads, but it would be too expensive to do much except in very stony parts.

8. Have found I require a less number of coolies for plucking since I started paying Tamils by the lb. instead of by the day.

9. Have always seen small plots given to coolies round the lines.

10. No, each boutique would sell illicit arrack.

11. No, but arrack is obtainable by the coolies on the edge of the estate, and I have reason to believe is likewise sold in the lines. Nothing will do any good in this direction unless we can get the co-operation of the renters.

C. H.

No. LVII.—MEDIUM DISTRICT.

1. Yes, they save a great deal of labour, and the damage done to leaves is very slight.

2. ?

3. No experience.

4. Yes, it is often overdone, but occasional weeding is very expensive in Ceylon where weeds grow all the year round. In India from October to March no weeds grow.

5. No.

6. No.

7. The litter from grevilleas saves wash very much and keeps down weeds.

8. ?

9. Coolies work far less when they have large gardens; they are very fond of living on their gardens and cattle. I am strongly against large gardens and cattle.

10. No.

11. Yes, they are a great curse, and spoil the good effect of cash plucking.

F. J. H.

No. LVIII.—HIGH DISTRICT.

1. Too constantly working. Yes, unless much care is exercised they *do* injure the leaf.

2. ?

3. Tramways owing to formation not practicable except on very flat estates.

4. Weeding not overdone, *scraping* has been.

5. No. Remove "karandies."

6. No, no.

7. Closer draining and more frequent cleansing of drains very desirable; where land is very steep cuscus might be tried on upper side.

8. ?

9. Give more accommodation. Build lines and as a rule they will be occupied. Allow cattle and goats and provide accommodation for them.

10. Caddies, as a rule, are quite near enough and sufficient.

11. No.

B.

No. LIX.—HIGH DISTRICT.

1. Wire shoots are probably applicable much more freely than at present on estates. They damage tea leaf a little.

2. ?

3. No experience.

4. Weeding may be overdone in Ceylon, but kanganies will not stay on estates unless they have weeding contracts given them.

5. Selected weeding might be advisable, but no moss or lichen should be allowed to accumulate on the stems of the bushes.

6. No experience.

7. The present system of draining is, as a rule satisfactory.

8. None to suggest.

9. I believe it always pays to give ground for gardens to coolies. Coolies with good gardens are those who think twice before leaving.

10. Yes, certainly.

11. Liquor shops might be reduced with advantage. Arrack is, however, smuggled into the lines on every estate, as is well-known.

O. C.

No. LX.—HIGH DISTRICT.

1. I have had experience with both shoots and wire tramways on Hunasgiriya. Shoots will do well for bringing firewood near the factory, provided there is wood growing or to be procured on the estate from any point where the gradient is sufficient. I should think a wire shoot would damage and bruise tea leaf; but a *wire tramway* with endless wires at a suitable gradient, and wheels with grooves on each wheel, also a brake to regulate the speed, would be correct for transporting tea from higher elevations. Every estate has not the lay of land suitable for a wire tramway of the kind I write of. I have used wire tramways for artificial and bulk manures frequently and with success, especially in bringing back bags or manure sacks.

2. Carts could be used more frequently.

3. Yes; very possibly.

4. Weeding.—I have no reason to believe weeding has been overdone in Ceylon. I knew that Indian planters have remarked this; but coolie labour being expensive in Ceylon the general system of weeding contracts given to kanganies helps to keep a labour force, and I fear that any change of system would check a labour force. Selected weeding might be tried, but the Tamil being very conservative I do not think it will answer: as it is, the clean weeding, done in the coffee days, has not the attention given now to tea on account of daily plucking.

5. I cannot say; but a great deal of moss is left while weeding on many estates.

6. No, I have not; but I should like to see it tried.

7. I would suggest where *practical* a large pit or dam be constructed at the bottom of the estate and all drains directed to this pit. It has been done before with good results: possibly several pits should be dug, but many estates have not the lay of land for one pit.

8. A better Labour Ordinance; the one of 1865 was more for coffee; but tea being a daily product the present Ordinance is unsuitable.

9. During my experience all or most coolies have gardens; if not given they are generally taken and enclosed.

10. Yes, until two or three estates have their own; also bring rice for coolies on to the estate.

11. Not now. No, I do not think liquor-shops should be abolished, as coolies, if they want liquor, will procure it some way or other; but I would reduce them in number in the planting districts.

J. N.

Note.—I consider the first thing necessary in planting is a new Labour Ordinance suitable for the tea product, Agents in India to help the cheated cooly, and longer terms of agreements with coolies and kanganies. Possibly bring a "Register Ordinance" in force, to prevent continual running away of coolies, and I would even suggest a legal visitor or Magistrate for coolies on estates to settle all their family and caste quarrels, also to act as a civil commissioner to decide all irregularities with respect to debts, as I know personally the present labour force is disorganized by kanganies and heads of families; possibly a visit once in four months would suffice.

NO. LXI.—HIGH DISTRICT.

1. Yes; but not for leaf. No reason for damage unless the shoot is too steep when the check cord could be used.
2. They have been pretty well utilized in all well-going factories.
3. Only on exceptional estates.
4. Clean estates, weeded under a rupee, should be kept clean, with drains in proper order. Dirty estates, far better left, save taking out coarse weeds and the surface stirred over with a mamotte once a year to prevent a too compact surface forming.
6. No; have no experience of the process.
7. Drains are often traced too steep; one in 25 should not be exceeded. Cuscus grass will rob three feet above it and grow too rank.
8. A good kangany, good tools, and task work, where practicable.
9. They usually cry for gardens, when there are none; when plenty space for them, gardens are usually quite neglected.
10. A bazaar under the head kangany is useful, but coolies like to go where they please.
11. Liquor shops are bad, and unnecessary; but here I never see a drunk cooly. I have plenty of labour and no advances out.

THIRTY-THREE-YEARS-AT-IT.

NO. LXII.—MEDIUM DISTRICT.

1. Yes! they can be used more freely than they are at present, especially on steep estates of large acreage. It does to some extent damage tea leaf, dependent more or less on the length and gradient of the shoot.
2. Usual machinery in factory.
3. Not in every instance, but it may be profitably used, where great distances have to be covered and where a dip exists between the starting point, and that to which goods, &c., are sent.
4. Yes; where the hoe was necessarily used.
5. No; but would suggest, that the hoe and karandi be dispensed with, and the kotchhie used instead, and every weed being pulled up as far as practicable. This would not loosen the surface soil, and consequently there would be less wash.
- 6.
7. Planting tea in hedges, both above and below roads and drains, will to a very great extent catch up the soil and prevent wash. There is no method yet found out, that can be practically applied towards preventing all the soil from being washed away.
8. A rough estimate before a work is started, as to its cost, and the work done thoroughly (allowing in for good and substantial work) will save a great deal of trouble and expense and be cheapest in the end.
9. Leave the cooly to look after his comforts and he will always be contented; but if you attempt to administer towards his comforts, you will breed discontent and he will never be happy. The cooly is happiest when he is the most ignorant; if attempts

are made to over-educate him, he will no longer be a cooly, for, when thus, he will not care to do the work of a cooly, but will look upon it as beneath his dignity to do such work. The best thing is to give him his wants and let him alone.

10. Yes.

11. No. If arrack shops were abolished in the planting districts, estates would get on very much more satisfactorily than at present.

W. S.

PLANTING NOTES.

"WILL COFFEE-GROWING PAY?" asks Mr. D. Buchanan, Manager, State Nursery, Mackay. He answers:—

I would advise all those who are in doubt about the matter to visit the State Nursery and see for themselves the crops on the trees here. Mr. Dansy, manager of the Mackay Coffee Company's estate, says he has not seen a better crop in Ceylon. I feel sure that a good future is in store for the coffee-growing industry; and it is just those farmers who have 30, 50, or 100 acres of cane who can go in for coffee successfully, as they have money coming in to tide them over the three years during which they have to wait for a crop.

DOUBLE RICE.—In the *Proceedings of the Asiatic Society of Bengal* for April 1896, Dr. D. Prain describes and figures what is known in India as Double Rice. In all cases the phenomenon was found to be due to an increase in the number of ovaries, the other parts of the flower being invariably of the normal number. In the gynæceum of over 150 flowers examined not one was found with fewer than four ovaries, all apparently perfect; the usual number being five. A few flowers were found to have six, and one or two had seven ovaries. When five, six, or seven ovaries were present, sometimes only three, but usually four or five appeared to be perfect. The ovaries may be one-, two-, or three-styled. Usually only two ovaries develop into grain, sometimes three, and their shape is modified accordingly.—*Kew Bulletin*.

RUBBER-TREE LANDS.—The National Congress of Bolivia have issued decrees declaring all rubber trees, or other wild trees or plants, available for industrial purposes, which may grow in forests or lands not legally held by individuals or duly authorised Companies, the property of the Government. In doing so, the Congress, however, promise important concessions to natives or others exploring the public forests in search of rubber trees. Concessions are to be granted by "estradas," or groups of one hundred and fifty trees, and actual proprietorship will accrue to those who reside in the community for a period of five years. Unless actually authorised by the Legislative Chambers of Bolivia, no individual can hold more than five hundred estradas, and no Company more than one thousand. The expenses attending the grants (15 Bolivian dollars) are payable by grantees and may be extended over fifteen years. Discoverers of rubber trees will have the preference in the granting of concessions. Certain rules are made for the protection of labourers employed on the lands included in these concessions, but they do not seem unduly stringent, though they throw a great deal of responsibility on the grantee. There has been recently formed in London, the Columbian India Rubber Exploration Company (Limited) with a capital of \$1,500,000, it being the outgrowth of an agreement made on April 2, 1897, between the Columbian Syndicate, Limited, and Mr. R. Alena as Trustee for the new Company. The object of the Company is to explore, obtain concessions and carry out the business of India-rubber tree growers and merchants.

PARA RUBBER, COCOA AND LIBERIAN, says a Ceylon correspondent from Kandy to *Planting Opinion*:—"People are talking a lot about this para rubber, and I hear of some being planted. We have a hundred plants or so doing very well. I also hear of Liberian coffee being cut out as a failure. The cocoa ground here looks good enough for anything and carries a fair crop, but parts are being planted up in tea, which does not look like a paying concern."

TEA MACHINERY.—We ought to have directed the attention of planting readers to the criticism of Tea-preparing Machines and especially of Driers, by "Engineer" in a letter which we reproduced from the "Indian Planters' Gazette." We should like to know what experienced Factory Managers in Ceylon have to say on the criticism therein offered. "Engineer" is severe on Assam withering houses and says:—"A properly equipped withering house should turn out the leaf at a given hour should it be wet or dry."

PROGRESS AND AGRICULTURE IN ZANZIBAR.—We have received copies of a new Zanzibar journal "The Shamba," to which we wish all success. It quotes the "Tropical Agriculturist" about iron ploughs introduced into Madras and adds:—

We in Zanzibar have not yet reached the wooden plough stage, which is against us. There are now some iron ploughs and other iron implements on their way from England, which if successfully tried might help us to dispense with a period of probation with the wooden article; though a wooden plough would be better than none at all. We feel sure that the question of agricultural implements should be taken up by Arab planters.

It is interesting to learn about rainfall in Zanzibar:—

The total rainfall for May was 12.21 in 9.04 in. of which fell on five consecutive days, May 19-23, when the Mvera Bridge was washed away. Though more than a month's dry weather has elapsed, the small lakes of water which were then formed, have not yet disappeared, and mosquitoes are the consequence. The average rainfall for April and May for the 5 years 1880-4 was 10.24, and 10.12 in. respectively, according to the reports published by Sir John Kirk, making 20.36 in. for the two *maskika* months. This year it was 15.12 in. for April, which with the 12.21 for May, makes 27.33 in. for the *maskika*, so we have had a wet time of it altogether.

The average annual fall should be given.

The clove crop is the most important:—

Reports have come in which show that the clove crop is not so promising in the north as in the middle of the island. The prospects in the neighbourhood of Kokotoni, and to the north of that, are not so good as they were last year.

CLOVES.—The stock of cloves in the London market on May 8 was 83,257 bales, the imports to date being 12,223. This shows that 71,036 bales of last year's crop have not yet been disposed of. The corresponding figures for each year since 1893 are:—

Stocks in hand	Imported to date (May 8.)
Bales.	Bales.
1893 45,804	25,656
1894 53,535	23,141
1895 78,507	26,461
1896 79,479	8,199
1897 83,259	12,223

Here is a useful reference:—

As we shall frequently have occasion to refer to an acre of land and as many of our readers may not be familiar with its measurement, we give below a few figures. An acre of land measures:—

220 yards long and 22 yards broad	
110 " " 44 " "	
88 " " 55 " "	
69½ " " 69½ " "	

A yard is a good long stride: few men step a yard in their natural stride. There are two yards in a pima: one mile long and one mile broad is 640 acres.

CEYLON BAMBOOS TO GERMAN EAST AFRICA.—The N.-D. L. ss. "Sachsen" took away from Colombo, a well-packed box containing several shoots of bamboos of various varieties to Aden, to be transhipped thence to German East Africa. The plants are despatched from the Peradeniya Botanical Gardens. We believe they are sent at the request of a German gentleman as an experimental measure to introduce the bamboos to African soil. For a new country the bamboos should prove not only an ornamental plant, but one of great use for many purposes. Several kinds of the wild *bata* and cane are included in the outgoing shipment and as our readers are aware, one of this kind is profitably used in the manufacture of tea-plucking baskets.

COCO-PALMS AND LOCUSTS.—Mudalyar Dassanayake brought to us recently part of a leaf of a coconut palm nearly all eaten away and a bottle of large bright-coloured creatures, pronounced at once to be huge grasshoppers or locusts—though the natives say they never saw such before. In Hapitigam Korale, the Mudalyar said, palm branches were literally covered and riddled by these enemies. Mr. Stanforth Green kindly reports as follows:—

"Locusts—These usually appear in large numbers. They are of a most destructive species." The visitation is a most unusual one, and we trust the locusts may as suddenly disappear as they have come. Have they been seen in other districts?

MR. NATHAN SHARPE, an interview with the Inventor of the "Simplex" tea machinery is reported in *Indian Planters' Gazette* of July 17th, accompanied by a portrait. The information given is very much what we had before in Ceylon; but we may quote the following:—

Mr. Sharpe hopes to get some oxidisers at work on the Darjeeling gardens later on, and to lessen the time now taken up by the process of fermentation in those parts, and at the same time improve the standard of quality. Mr. Sharpe has received orders from the three largest estates in Ceylon for his machines, *viz.*, Mr. Lipton's Lemastotte Factory, Dambatenne Group, the Diyagama estate and the Bandarpolla estate, and has promises of a good amount of orders for next season from Indian estates. The machines are all manufactured by the well known engineering firm, Messrs. Richard Moreland & Son, Aldersgate, London.

THE COFFEE OUTLOOK.—In the coffee market the influence of that bogey, the Brazil crop, is paramount. Speculation in "futures," which is supposed to rule the coffee market in the main, is still of a sorry character, and the downward tendency in prices goes on unchecked, says the *Grocer*. "Sagging," to use a familiar term, has been the order of the day with operators in coffee for several months past, and the decline in quotations for inferior and common qualities since the beginning of the year has been a very serious matter for holders. The prodigiousness of the Brazil crops for the 1896-97 season—which we have before pointed out—has been the sole cause of the prevailing depression, and until their full extent is known or realised, and the bulk of the coffee has been delivered, no solid improvement can be expected. With the 30th ult. the old season ended, and recent cables give the total receipts of Rio and Santos at the Brazilian ports, since July 1, 1896, as 8,680,000 bags, in comparison with 5,489,000 bags in 1895-96, also 6,699,000 bags in 1894-95, and 4,307,000 bags in 1893-94. Here we have a crop representing about twice the amount grown and gathered four years ago, and likewise materially heavier than what was then—in 1891-92—regarded as the largest yield ever recorded, *viz.*, 7,386,000 bags, consisting of Rio and Santos in nearly equal proportions. Now, however, the excess is composed chiefly of Santos, which description has yielded over 5,000,000 bags of coffee, as contrasted with 3,100,000 bags in the previous season, and only 1,750,000 bags.

PLANTING AND TRADE IN THE PERAK STATE IN 1896.

We have to acknowledge receipt of the Annual Report on the State of Perak for last year by Mr. W. H. Treacher, C.M.G., British Resident. It is a full and valuable statement of progress under the various heads of administrations with very copious statistical returns in appendices. At the outset we note there has been a falling-off in General Revenue last year, by less than 2 per cent on that of 1895; but quite 6 per cent below the Estimate. This is attributed to the low price of tin and a decreased output. The total trade too shows a falling-off as follows:—

Value of Imports	..	\$ 8,713,940
do. Exports	..	14,289,680
<hr/>		
Total value of Trade, 1896		23,003,620
do. do. 1895		25,177,597
<hr/>		
Decrease, 1896	..	2,173,977

We are told a good deal about Public Works and Surveys trigonometrical and otherwise, and great activity is manifest in respect of Railways. At present there are open the Larut line 17 miles and the Kinta Valley line 51 miles. Then as to further progress we quote as follows:—

EXTENSION TO PENANG.—In the absence of any port worthy of the name, Penang (Kuala Prai) is the natural Port for the northern portion of this State, and the extension thither of the Larut line, at a small cost per mile, by arrangement with the Colonial Government, though flourishing agricultural country, would be of benefit both to Perak and Penang, and in all probability yield a fair return on capital expended. The distance is about 50 miles, of which 24 miles would be in colonial territory.

CONSTRUCTION.—During the year the extension of 13 miles from the terminus at Ipoh, via Tanjong Rambutan, to Chemor, was opened to traffic. Saucation was obtained for the extension of the line from Chemor to Kuala Kangsar in June 1896, a distance of 22 miles. Work was at once commenced, and by the end of the year about six miles of formation were completed. It is hoped that the extension will be opened to Sungei Siput, 12 miles from Kuala Kangsar by the end of June of the present year. A sum has been provided in the estimate to complete the line into Kuala Kangsar, by the close of 1897, with the exception of the superstructure of the bridge over the Perak river, which will probably cost \$130,000 and should be put in hand at once.

SURVEYS.—The survey of 16 miles from Chemor to the Perak river was completed, including selection of site for the river crossing. The survey thence to Taiping is being rapidly performed, and the hope is indulged in that the old trace may be somewhat improved upon and the anticipated cost of the tunnel at the pass be reduced.

Trial surveys for proposed extension from Tapah Road to Tanjong Malim, on the Selangor borders. The Resident Engineer for Railways reports 58½ miles of trace cut, surveyed and levelled, seven miles cut and surveyed, 47 miles cut only. As far as can be at present ascertained the line will be easy and the length under 50 miles, but for nearly the entire distance it will be through heavy forest, and some considerable deviations will be required to avoid heavy works.

Towards the close of the year a commencement was made with the survey from Ulu Sa'petang to Parit Buntar (Kuala Prai extension.)

FURTHER EXTENSIONS.—Extension to Kuala Prai, 50 miles.

Joining up the 20 miles between Taiping and Kuala Kangsar. This will be essential to complement the proposed extension to Kuala Prai and to form a continuous line of railway from Kuala Prai, the northern port, to Teluk Adson, our southern port. It is, in any case, manifestly desirable to connect the Larut and the Kinta Valley Lines by the construction of this

proposed 20 miles of line, which has now been in contemplation for some years.

Tapah Road to Tanjong Malim, *i.e.*, to the Selangor boundary. Distance about 50 miles. I am not in a position to express an opinion as to this extension. The district has not yet been opened up by roads, and I have seen no reliable report as to the capabilities of the country through which the line would pass. There are, doubtless, tin deposits, but the probability is that the railway will, to keep down cost, run even further away from the cross valleys which contain the deposits than does the cart-road now under construction. Again the richer deposits, it is anticipated, will be found towards the Selangor boundary, and the natural route to the sea would be the Selangor-Kuala Kubu line. The soil of many parts of the district is reported suitable for European plantations.

The time has arrived for a forward policy in railway extension, and for connecting the existing lines. In the past we, in Perak, have constructed our short pieces of railway, not out of current surplus revenue alone, but with the assistance of the surpluses accumulated by the wisdom of Sir Hugh Low, during the period when the question of Native States railways was in its infancy. We have no longer these accumulated surpluses to fall back upon, and if we are to extend it must be with the assistance of a loan. To employ any small amount of surplus revenue that can annually be provided in carrying out slight extensions, which can bring in no return until the completion of the scheme of which they form part, is hardly a judicious policy.

But to us in Ceylon the most interesting information is contained in the following:—

THE TOTAL ACREAGE OF EUROPEAN COFFEE ESTATES, Liberian with one exception, opened, or being opened, in the State by the end of 1896, is given as 35,242 acres (approximate). On the whole the reports from these estates are encouraging. Six thousand four hundred and five acres of new land for European coffee estates were given out during 1896.

Batang Padang is the district in which Malays have made most progress with the cultivation of coffee, and the District Magistrate reports:—"A very large amount of coffee has been newly planted by the Malays and three large blocks of land for the same purpose have been applied for by Europeans. I hope their example will lead to others coming into the district, which ought to be one of the finest in the State for coffee planting." In other districts Malays and Chinese are increasingly interesting themselves in this culture.

PEPPER.—The improved price of this article has caused the natives to pay some attention to their few and neglected pepper plantations but, except when high prices rule, this culture does not appear to attract our natives. One European planter has found that he can obtain very profitable prices for his white pepper.

COCONUTS.—Some of the European planters are now alive to the solid advantages to be derived from coconut plantations and are planting to a considerable extent. The soil and climate appear to be admirably suited to the requirements of this palm, in the inland as well as in the coast districts. Natives in different parts own not inconsiderable plantations and efforts will be made to encourage them to extend. In the Matang district the Chinese proprietor of a tapioca estate of 692 acres has planted 300 acres with coconuts and is extending his plantation.

RAMIE.—The subject of ramie cultivation, as the Resident-General is aware, has not escaped the attention of the Perak Government, and thanks are due to Mr. L. Wray, the Curator, for the trouble he has undertaken in investigating points connected with the subject. The results of his investigations are not yet ready in a shape to be placed before the public. The plant has been grown for ages by the natives, in very small quantities, for their own use, and our rainfall and climate generally are said to be especially favourable to its growth.

BANANA FLOUR.—A new industry, the preparation of banana flour, has been inaugurated on a trial scale by one of the European coffee planters. Good quotations have been given in England for small samples, and hopes are entertained of the success of the experiment.

Mr. F. D. Osborne presented samples of some particularly well-cured Liberian coffee, grown near Gopeng, in the Kinta District, as to which the Curator writes, "this coffee has been fetching a better price in Singapore than any other produced in the Straits. The high value placed on it has been due to its colour and not to any superiority of the bean." He continues, "the Liberian coffee grown on the hill at Waterloo Estate apparently has a finer bean than any from the plains. Some trees planted by Mr. Cecil Wray in 1880-81 are well-grown, vigorous bushes, in full bearing, while trees of four years old, planted by Sir Graeme Elphinstone, on the same estate, on land cleared twelve years previously, compare most favourably with bushes of the same age on the low lands, planted on newly cleared forest land."

SALT IN AGRICULTURE.

A planting correspondent writes:—"You have placed agriculturists of all classes under a great obligation by the handy compilation you have just issued from the *Observer* Press. One great obstacle to effective and persistent agitation on any matter, is the difficulty of bringing the information bearing on it, and scattered in diverse ephemeral publications, into a focus. In respect of the value of salt for agricultural purposes, of the restrictions placed on its sale for other than culinary purposes through the Government monopoly, and of the manner in which similar obstructions have been overcome in Germany, admittedly one of the most progressive and scientific countries in the world, we have all the information now collected in a handy form in the little booklet, which is cheap at 50 cents. Its publication should not only strengthen the hands of those who are agitating for a relaxation of the stringency of the conditions under which salt is now sold, but it should also stimulate inquiry on the part of planters of all products, so that they might test the utility of salt in the cultivation of different products. The value of salt for stock is beyond all question, and is admitted and recognised in all countries."

RUBBER CULTIVATION IN CEYLON.

We give below the papers embodied in the Sessional Paper compiled in answer to Mr. Chamberlain's brief despatch giving cover to a letter from Kew. Neither Mr. Brown and his

able assistant, Mr. F. Lewis, nor Mr. Willis add much to our practical knowledge on the subject, although Mr. Willis's estimate of 750 acres being now planted with rubber in Ceylon is a safe one. Our latest Directory compilation gave 634 acres and we should hope the returns we are just about to call for, in order to make up a fresh Directory estimate, will show an increase of at least fifty per cent in area. The experiments in "tapping" promised by Mr. Willis will be looked for with much interest.

The Right Hon. J. Chamberlain, M.P., to Governor the Right Hon. Sir J. West Ridgeway, K.C.B., K.C.S.I. Downing street, April 23, 1897.

Sir,—I have the honour to enclose, for such action as you may think fit to take, a copy of a letter from the Director of the Royal Botanic Gardens, Kew, calling attention to a report on the cultivation of rubber-producing trees in Mexico, and suggesting that the subject should be entertained by your Government I have, &c.,

J. CHAMBERLAIN

The Director, Royal Gardens, Kew, to the Under Secretary of State, Colonial Office.

Royal Gardens, Kew, April 20, 1897.

Sir,—You have no doubt observed that the employment of indiarubber in the industrial arts has of late enormously increased. This substance is obtained in the tropical and warmer parts of the world from trees occurring spontaneously, and which have to no appreciable extent at present been subjected to cultivation. Apprehensions have therefore been expressed that the supply at no distant date may be very much restricted.

2. On this point without accurate information it is difficult to give a positive opinion, but it must be admitted to be extremely probable. It is therefore not surprising that projects have been formed to grow plantations of rubber-producing trees artificially. I am anxious to draw the attention of the Secretary of State to the account of an enterprise of this kind given in the accompanying report by Her Majesty's Minister in Mexico.

3. Twenty years ago the Secretary of State for India in Council invoked the aid of this establishment to introduce the species yielding indiarubber in South America into India. The operation was successfully accomplished at considerable cost. Three species were established in Ceylon, where they have since produced seed, which is available for distribution. As far as I am aware, no practical result has followed. Yet it cannot be doubted that there must be many spots in our Eastern Colonial Possessions where rubber cultivation might be prosecuted successfully. I venture to think that the matter is one to which the attention of the Governments of Ceylon and of the Straits Settlements might be properly drawn. Probably if a memorandum were issued by the botanical officers of these colonies pointing out the culture, conditions suitable to each species and the source from which seed could be obtained, planters would engage in the enterprise.

4. In recent years a tree (*Kiknia africana*) has been discovered in West Africa which yields a rubber of excellent quality, and this has become the basis of a trade of great magnitude. Seeds of this tree have been sent from Kew to the Botanical Departments of Ceylon and of the Straits Settlements.—I am, &c.,

W. T. TRISELTON-DYER.

The Conservator of Forests to the Hon. the Colonial Secretary.

Office of the Conservator of Forests, Colombo, May 20th, 1897.

Sir,—With reference to your letter No. 195 of 18th instant I have the honour to state that the pamphlet enclosed therein deals with the Castilloa rubber.

2. The late Dr. Trimen recommended the plantation, not of Castilloa, but of Para rubber plantations, and in consequence the Forest Department plantations have been made with the latter species.

3. I have already requested the Assistant Conservator to make an estimate of plantations on a larger scale than has hitherto been done, and as soon as it is submitted I shall forward it with my remarks.

4. I can however state here that if a large plantation is taken in hand it will be necessary to have a special superintendent in charge of the plantation for the Assistant Conservator, with his numerous duties requiring his presence in different parts of two Provinces, will be unable to devote sufficient time to a plantation which requires constant supervision.—I am, &c., A. F. BROWN, Conservator of Forests.

The Conservator of Forests to the Hon. the Colonial Secretary.

Office of the Conservator of Forests, Colombo, May 25, 1897.

SIR,—In continuation of my letter No. 202 of 20th instant I have the honour to annex copy of a report on the subject by the Assistant Conservator of Forests, Western Province.

2. Mr. Lewis proposes to plant 300 acres per annum, and submits an estimate for the first year amounting to R10,202, or R34 per acre. Against this expenditure he shows an estimate of revenue from the sale of timber, firewood, &c., amounting to R4,200. The net expenditure would therefore be R6,002, or R20 per acre for the first year. To this amount would have to be added the expenditure in the second, third, and fourth years on weeding and supplying, which I expect would amount to R12, R8, and R5 per acre, respectively.

3. To my mind, if such a place can be selected I would much rather keep the plantations in one block than open a number of different plantations at various points. Such a multitude of plantations would not only increase the cost of fencing and watching, and the cost on a larger number of cooly lines, but it would do away with the advantage of having a special superintendent always on the spot.

4. If Government wishes the work to be taken in hand, I shall early next month inspect the place near Pelenda where the Assistant Conservator proposes to start work. It will also be necessary to issue instructions to the Director of the Botanic Gardens to reserve all the seed from the trees at Henaratgoda for our plantations.

5. Finally, I beg to point out to Government that the expenditure on these plantations lessens the chance of a surplus for the Department, and that if it intended that the Forest Department should show an increasing net revenue, the starting of these plantations should be put off.—I am, &c., A. F. BROWN, Conservator of Forests.

The Assistant Conservator of Forests, Western and Sabaragamuwa Provinces, to the Conservator of Forests.

Colombo Kachcheri, 20th May, 1897.

RUBBER CULTIVATION, PASDUN KORALE AND KUKULU KORALE.

SIR,—With reference to our conversation at Avisawella on the 12th instant, regarding the further addition to the area of land under rubber cultivation, I have the honour to state that I think it issossible that at Pelenda in the Pasdun Korale, and in the delta formed by the Pelan-ganga, Kukulu-ganga, and Maguru-ganga streams, that the total extent might be brought up to say 3,000 acres.

2. I may remark here, however, that the question of area is not so difficult as the selection of land of a suitable degree of flatness, situation, soil, and elevation: for, while it is perfectly possible to find an even larger extent, experience shows that it is undesirable to plant steep hill sides or swampy lands, or lands in which the soil has a high percentage of sand in its composition, with this product.

3. Under these circumstances it is extremely difficult to find a continuous piece of land with all suitable conditions, and therefore I would respectfully suggest that selected areas be first fixed upon, and

if their success will justify it they could in many cases be connected by opening the intermediate areas.

4. I am of opinion that in this way a most profitable block of 150 acres could be obtained in the owita lands in the Kukulu korale; where there are 850 acres of this sort of land, but I think it would be unwise to select any below flood level, and so I restrict the proposed extent there to 150 acres. I have a further reason for suggesting this land in particular, as it is both flat and fertile and might be specially worked as a centre for raising seed, for which it is reasonable to anticipate a very large demand as rubber becomes known as a permanent industry; and judging by results of areas set apart in tea for seed bearing, it is not unreasonable to anticipate a very large revenue from this source alone.

5. I may moreover point out that local labour in the Kukulu korale is not in such demand as in other places, where tea estates absorb all available hands for plucking, &c., and therefore be easily obtained by us.

6. I would venture to suggest that 300 acres of rubber per year might be opened, and that operations might begin at once this year, by selection and survey of suitable blocks, and preparatory extraction of all timber that could be first disposed of; and if this is done under European supervision I anticipate that the return by sale of timber and firewood would more than pay the salary of the officer in charge, thus securing the services of one who would be able to devote his entire attention to the proper management of the plantations at practically no cost to the estate. I submit that constant supervision is essential to the proper management of such a plantation that I propose, to increase by 300 acres yearly, and for that purpose I have estimated for a European Assistant to be under my orders.

7. Annexed will be found an estimate for opening 300 acres at once, to be planted early in 1898 with plants to be first grown in a nursery, for which purpose all the seed at Henaratgoda should at once be secured; and I may add that I have, in anticipation, communicated with the Director of the Botanic Gardens to know what quantity can be obtained.

8. Finally, I would beg to be informed with as little delay as possible if I may make arrangements for the selection of 300 acres of land, and if the estimate may receive sanction.—I am, &c.,

FREDERICK LEWIS, Assistant Conservator of Forests.

ESTIMATE OF COST OF OPENING AND PLANTING 300 ACRES OF FOREST LAND WITH RUBBER: PASDUN KORALE.

	R
Felling and clearing 300 acres of forest at R12 per acre	3,600
Lining 300 acres 10 ft. by 10 ft. at R2 per acre	600
Holing 300 acres at 75 holes per cooly, at 40 cts. = 120,000 ÷ 75 by 40	697
Filling and planting and carrying plants from nursery to holes, 300 per cooly, at 40 cts. = 120,000 ÷ 300 by 40	175
Draining: 300 ft. of drains per acre at 1 ct. per ft. run	900
Lines for coolies: one shed of 10 rooms of 12 ft. by 10 ft., mud walls and battocalla roof, at R30 per room	300
Roads for inspection: 2 miles at R80 per mile	160
Bungalow for Assistant: improvements to present building at Midellana plantation	75
Plant nursery, including watering of seed beds	150
Wedding (assuming the opening of the land to be in July 1897), at R1 per acre, for six months = 300 by 6	1,800
Cost of surveying lines round plantation, say	75
Contingencies, such as special work, bridges over streams, or supplying vacancies, &c.	250
Total actual outlay	8,782

SPECIAL EXPENDITURE.

	R.	c.	
Salary of Assistant, for one year	1,000	0	
Cooly to carry letters and orders	120	0	
Tools (cost of supply)	300	0	
			1,420 0
			10,202 0

ESTIMATED RETURN OF 300 ACRES OF FOREST TO BE PLANTED WITH RUBBER.

	R.	c.
600 trees sold standing at R2 per tree	1,200	0
Value of firewood and "rittii" after deducting cost of working: R10 per acre	3,000	0
Total to credit of first year's work ..	4,200	0

The Assistant Conservator of Forests, Western and Sabaragamuwa Provinces, to the Conservator Forests.

Colombo Kachcheri, 9th June, 1897.

SIR,—In acknowledging receipt of the Hon. the Colonial Secretary's letter to you No. 211, and here-with returned, I have the honour to report that in 1890 a small plot of 15 acres was selected at a place called Edangoda, in the Kuruwitii korale in Sabaragamuwa, and planted with Para rubber. The land was selected close to the Kalu-ganga, and at certain periods of the year it was subject to floods. As the late Dr. Trimien was of opinion that as similar land in its native habitat was best suited for this species of rubber, I laid out my plantation in such a situation as would best correspond with these conditions.

2. It was found, however, that these periodical inundations were harmful, and that plants below flood level were destroyed, notwithstanding much attention having been paid to the supplying of vacancies. By this loss about one-fourth of the Edangoda plantation was destroyed, but of the remainder above high water mark I cannot speak too highly. The trees are in robust health, and form an unbroken cover of trees of some 20 feet in height and from 15 to 20 inches in girth at four feet from the ground. Some 275 trees are this year in fruit at the Edangoda plantation, and I anticipate getting a crop of 30,000 seeds that will be available for use during the present year.

3. In 1891 the Edangoda plantation was extended by one acre, and at a place called Yattipowa, six miles from Edangoda, a second plantation of 16 acres was planted, and in 1892 a further addition of 21 acres more, while as an experiment in chena soil 5 acres of chena land at Edangoda were planted, thus bringing the total area in rubber to, say, 58 acres.

4. The Yattipowa plantation is, on the whole, very successful, the only exception to its general regularity of growth being found upon a ridge where the soil is inferior and the wind appears to check the growth. This is only a very small piece and is quite compensated for by the satisfactory growth of all the rest of the plantation.

5. I am not so well pleased with the experiment of planting chena land, as it has shown a thin and weedy result in trees, but the general conclusion I have drawn from the experience gained is that flooded lands, wind-swept lands, sandy soils, and wide apart planting are equally unfavourable to the successful cultivation of Para rubber.

6. I am not in a position to give any information as to yield of the trees, as it has been deemed inexpedient to attempt to tap any of them, but for my own information I selected a solitary tree and obtained from it, from a single wound, a "tear" of pure rubber about 4 feet long and one-third of an inch wide, that when dried appeared to be of excellent quality. The oldest trees being only seven years old, I have not attempted to ex-

periment further, but I hope to be allowed to conduct a few tapping operations in order to test the yield per tree.—I am, &c., FREDERICK LEWIS, Assistant Conservator of Forests.

NOTE.—I wish to add that the foregoing distinctly applies to the Sabaragamuwa Province and that 27 acres have been planted in 1896 in the Western Province and not as yet added to the area in rubber.

No. 5.

The Conservator of Forests to the Hon. the Colonial Secretary.

Office of the Conservator of Forests, Colombo, July 5, 1897

SIR,—With reference to your letter No. 243 of 26th ultimo, I have the honour to inform you that on the 3rd instant the Director of the Royal Botanic Gardens and I had a conference on the subject.

2. The demand for Para rubber seed is now so enormous that Mr. Willis says if all could be supplied 100 square miles could be fully planted up. The supply from the Royal Botanic Gardens can only satisfy a very small portion of the demand, and even some private sellers have booked all their crops, charging R20 per 1,000 seeds. The Director therefore thinks, and I agree with him, that the publication of a notice offering seed to the public on payment would lead to a great deal of disappointment.

3. He proposes, as soon as he has completed a series of experiments regarding yield of trees of different sizes and ages, &c., to publish a bulletin in which will be included the results of our experience as regards soil and locality.

4. I have lately visited the most recent rubber plantation in the Pasdun korale and was disappointed to find that some of the young plants had suffered from some extraordinary floods, and that as compared with the plantations at Edangoda and Yattipowa, the initial growth of the young plants is very slow. The sand, which enters largely into the composition of the soil, does not seem to favour vigorous growth.

5. A further area of 75 acres has been cleared this year and will be planted up. They will yield further data as to the suitability of the Pasdun korale forests for rubber.

6. There is little doubt that the rubber plantations now made, will, if successful, pay handsomely. At present from the sale of seed alone R200 per acre could be obtained. I beg therefore for orders as to whether the Forest Department is to satisfy itself for the present with the plantations now existing and being planted up in the Western Province and Sabaragamuwa, or whether we are to make further extensions in Para rubber plantations.—I am, &c., A. F. BROWN, Conservator of Forests.

Report of the Director, Royal Botanic Gardens, on Rubber Cultivation in Ceylon.

Royal Botanic Gardens, Peradeniya, July 28, 1897.

The subject is one of great importance at present owing to the enormous increase of late years in the demand for rubber caused by the growth of the cycling trade and other industries in which rubber is consumed. That the price of raw rubber has not increased very greatly is chiefly due to the discovery in West Africa of a new rubber-yielding tree, *Kickxia Africana*. It seems likely that in a few years' time the reckless destruction of wild trees will cause the price to rise and that rubber-planting will thus become a profitable industry.

The trees yielding rubber are many, but most of them being large jungle climbers are unsuited for cultivation. The chief kinds likely to be useful in cultivation are Ceara rubber (*Manihot Glaziovii*), Panama rubber (*Castilloa elastica*), Para rubber (*Hevea brasiliensis*), and African or Lagos rubber (*Kickxia Africana*).

3. The cultivation of Ceara rubber was taken up in Ceylon about 12 or 14 years ago with some energy, but the returns were found unsatisfactory, though the plant grew very well indeed, and now there are but few trees remaining. Of Panama

rubber there is but little in Ceylon, and seed is only obtainable in extremely small quantities. The new Lagos rubber has only been introduced in the last two years, and the proper mode of cultivation and most suitable soil have yet to be discovered. The only rubber of importance at the moment is the Para kind, and the rest of this report refers only to it.

4. Para rubber was introduced into Ceylon in 1876, when the young plants obtained from Brazil at the expense of the Indian Government were planted in the Henaratgoda Garden. These are now very fine trees with an average height of 60 ft. and average girth (at 6 ft. above ground) of 4 ft., and from their seed other plantations have been made in the Botanic Garden and also by the Forest Department. A large number of seeds have been sold to private planters since 1886. The tree produces only a few seeds, the seeds are large and only retain their vitality for a very short time, and thus it is difficult to obtain seed from or send seed to distant countries. The crop produced by the trees (about 450) in the Botanic Garden is now about 75,000 seeds a year.

5. It is very difficult to obtain exact information, but I estimate the number of trees on private estates in Ceylon to be between 200,000 and 250,000, of various ages from one to ten years. This number represents an area of about 750 acres.

6. The present year has seen a sudden increase in the demand for seed. Hitherto the crop produced in the Botanic Garden has sufficed for almost all demands, but the applications for seed in 1897 have been numerous, and I could easily sell 30 or 40 times as much seed as is obtained from the trees in the gardens. The trees belonging to the Forest Department are only expected to yield 30,000 seeds this year, an insignificant quantity when compared with the demand.

7. The practice of this Department at present is to book seeds for delivery when ripe, in quantities of not more than 3,000 for one person, in the order in which applications are received. The price asked is Rs 5 per 1,000. A much larger price could now be obtained: private planters are obtaining Rs 20 per 1,000 seeds this year.

8. The present system of supplying seed is open to the serious objection that as 3,000 seeds are only enough to plant four or five acres, a planter really wishing to take up the cultivation on a large scale cannot do so within a reasonable number of years. It is desirable that greater encouragement should be given to planters to engage in this cultivation on a considerable scale, and that one man should be able to get as many as 40,000 or more seeds in one year. This would take nearly all the crop and would expose the Government to accusations of favouritism, which might be avoided if the seed were sold in large quantities by auction or by invitation of competing tenders. This method would also probably increase the revenue derived from the sale of these seeds. An undertaking should be required from purchasers to the effect that the plants shall receive proper attention and cultivation on areas of land devoted to the one crop only.

9. The area of land suitable for this cultivation is not very large. The plant for complete success requires fairly flat land at about sea level, with good soil, not subject to frequent floods and to heavy winds, and with a uniform wet climate. Only in parts of the low-lying south-western region of Ceylon are these conditions found. On the other hand, the cultivation of rubber need not interfere with that of coconuts, as it does not do well in sandy soil or near the sea, and it should thus form an additional cultivation in the Colony rather than replace any of those already existing by using up the land occupied by them.

10. Opinions are at present much divided upon the question whether this cultivation will pay. The wild sources of rubber are at present far from exhausted, but they are becoming every year more and more difficult of access, and the cost of transport increases the price of the rubber.

11. The answer to this question really rests upon the amount of rubber that may be expected to be yielded by the trees when at a suitable age for tapping (say about ten years old). The accounts given by those who have observed the harvesting in Brazil vary greatly: many mention extraordinary amounts, but neglected the fact that such excessive tapping usually causes the death of the trees. Almost the only reliable observations are those made in the Henaratgoda Gardens. The late Dr. Trimen tapped one of the original (1876) trees every other year from 1888 to 1896. The result showed that from tenth year onwards a yield of about $1\frac{1}{2}$ lb. per tree per year might be obtained. These trees being planted 30 feet apart the yield per acre would therefore be about 75 lb. of dry rubber a year. This is not sufficient to pay well. It would, however, be absurd to draw definite conclusions from experiments on one tree only. I have therefore commenced an extensive series of experiments in tapping, &c., upon a plantation of 11-year-old trees at Henaratgoda. These experiments are now in progress, and their results will be published from time to time. At present I can only mention this one fact, that the average yield so far of an 11-year-old tree is about 6 ounces a year, the trees being 12 feet apart. This represents an annual yield of 112 lb. per acre, which should pay fairly well. It is probable that the trees will be found to yield more than this without injury, but as yet I do not feel justified in making any definite statement upon this point. The price of good Para rubber in London is now from 2s. 6d. to 3s. 6d. a pound, so that a yield of 112 lb. represents a value in London of about £15 or £16. Considering the small labour cost of rubber, this should be enough to yield a good return upon the outlay.

My recommendations upon the question of rubber cultivation in Ceylon at the present time are as follows:—

(a) There being such a demand for seed by private individuals, I should recommend that the seed produced in the Botanic Gardens be sold as heretofore to such individuals, but in larger quantities, either by auction or by competing tenders.

(b) That the seed produced in the current year by the trees in the Government plantations under charge of the Forest Department should be used in planting the land which I understand to be already available for purposes of extension of those plantations, and that it be subsequently decided whether the seed of 1898 and following years be sold to the public or used in further extension of the Government plantations.

(c) That no further public attention be drawn to the question until after the seeding time for this year is past, when a bulletin should be issued from this Department dealing with the whole question of cultivation, yield, cost, &c.

(d) That in the course of the next year or two experiments in tapping on a large scale should be made upon the trees in the Government plantations, so as to ascertain, more accurately than can be done with the few trees in the Botanic Gardens, the yield of a plantation, the cost of collection and transport, and the price obtainable for the product.

JOHN C. WILLIS, Director.

RUBBER PLANTATIONS IN SUMATRA.

Numerous India-rubber trees are growing on the east coast of Sumatra in a wild state, and the natives have collected large quantities of rubber, to the great damage of the rubber-trees, which have become debilitated and in some cases extinct. Within the past few years wealthy Holland companies have created rubber plantations and in the Kassan district a not unimportant market in Sumatra rubber may be expected in the near future. An idea may be had of the remunerativeness of such plantations when it is guaranteed by the directors of the companies that 100,000 rubber trees will clear annually, above all expenses, from 500,000 to 600,000 marks. The editor of the *Gummi-Zeitung*, in which we find this note, expresses very grave doubts of such figures being realized.—*India Rubber World*.

PLANTING UP OF SHIFTING SANDS
NEAR DRESDEN IN SAXONY,

BY A. M. REUTHER, INDIAN
FORESTER.

A considerable area situated within the Dresden Forest Circle has since many years been leased by the Military Department with the object of providing parade-grounds for the Cavalry and Infantry Regiments stationed there. In 1887 it was decided to extend the parade grounds, for which purpose a further area of 100 hectares was included in the lease; and in order to obviate payment of compensation, the Military Department allowed the tree-stumps to be extracted, and the litter to be removed, from this area after the forest on it had been clear felled.

The surface-configuration of this area is undulating and the soil consists mostly of pure sand, containing here and there an admixture of clay up to 18 or 19 per cent. Very soon after the complete exposure of the soil, the sandy surface began to grow unstable, and already in 1870 the shifting sand, moved by the wind, covered not only the adjacent Cavalry parade-ground but also blocked the more distant "Königsbrücker" Chaussee to such an extent as to interrupt all traffic on it. In the next few years the evil assumed such large proportions that it was found absolutely necessary to reafforest the area with the least possible delay.

Operations were commenced in 1874 by covering the whole area with a network of wattled fencing. Strong stakes, 7 to 9 cm. in diameter, were driven into the ground 60 cm. apart, in rows 20 m. apart running south to north, and interwoven with branches of Scotch Pine, the wattled fencing thus formed being 80 cm. high. At right angles to these lines of fencing similar fences were made, about 50 m. apart, and 60 cm. high. Towards the west, where the general surface-elevation is higher and exposed mounds and ridges exist, the fences were placed closer together than on the more sheltered east side so that the average area of each rectangle enclosed by the fences was about 1 rood on the west, and about 2 roods on the east side. The shifting of the sand was thus greatly reduced, and restricted within the enclosures; and already in 1875 it became possible to begin planting. In that year birch and alder were planted in rows along the fences (on the sheltered side), the planting holes being filled with good soil brought from a distance—and in the following year planting up of the interior of each rectangle was begun with Scotch Pine plants 1 to 2 years old, which were put out in squares with the aid of Butlar's planting tool, 8,000 plants being used per hectare, and each plant supplied with a handful of good humus soil. The compost was prepared in autumn and left lying in heaps during the winter, and conveyed to the site of the plantation just before the planting season in spring.

RESULTS.—The results are quite satisfactory in so far as the ground is now fully stocked, and the surface-soil completely consolidated. But owing to the dryness and poverty of the soil, the growth of the plants is in many places very miserable, many of the Scotch Pines being only 1 metre high though already 15 to 18 years old. The average height is, however, about 5 m., and for the most part the plants have closed overhead. The entire area has been most carefully protected; cattle have been strictly excluded, and grass cutting disallowed, and all unauthorised persons have been prohibited from walking across it. These precautions were absolutely necessary to prevent disturbance of the unstable surface-soil, and to give the plants a chance of establishing themselves.

The cost of the cultural operations was 41.40 mk' per hectare. The wattled fencing was constructed by a local battalion of Pioneers, and therefore involved no direct outlay; had the work been done by paid labourers, the cost would have been about 0.20 mk. (21d) per running metre of fencing.

SALT IN AGRICULTURE.

MR. W. R. TRINGHAM sends us a couple of small pamphlets published by the "Salt Union Co.," on the manifold uses of their staple. Mr. Tringham says:—

The pamphlet "Agricultural uses of Salt" contains valuable information, for instance read General Observations p. 15.

We quote as follows:—

GENERAL OBSERVATIONS.

1. Salt should not, as a rule, be applied with the seed. A little salt is sometimes mixed with carrot seed, an exception to the above rule.

2. It is not advisable to apply salt to very cold, wet clay land. Salt nevertheless assists in the disintegration of clays, if applied before ploughing.

3. One of the principal reasons given by scientific authorities for the application of salt more or less to all soils is based upon the fact that Chloride of Sodium, like other soluble Salts, is constantly being carried off the land into the rivers and seas. If the soil is to be kept fertile, this unavoidable loss must be replaced. Bearing in mind the abovementioned fact, it will be seen that those who think the land near sea coasts does not require salt are in error, as the small amount of salt carried a short distance by sea breezes bears no comparison with the quantity carried away.

4. As a guide to those who wish to make experiments, we may say that a fair average quantity is two ounces of Salt per square yard. A rough calculation is one handful to each square yard.

6. Two cwt. of Salt to 1 cwt. of nitrate of soda, 1 cwt. Salt to 2 cwt. lime, equal quantities of Salt with basic slag, guano, and superphosphates, are usual proportions. Kunit generally contains about one-third common salt and in a report of recent experiments at Reading it is stated that "An equivalent amount of Salt to that contained in the Kunit dressing, has been equally effective."

The use of Salt for Agricultural purposes is by no means recent, as is evidenced by the fact that the Romans and Chinese used it as a fertiliser for centuries before the Christian era. Why its use has been so much neglected and undervalued in the nineteenth century is a mystery to many scientific men.

A provider of plant food. An absorbent. A purifier and cleanser. A destroyer of weeds and insects. Salt improves grasslands and renovates old pastures. Successful experiments with salt in the cultivation of grain crops. In the cultivation of flax Salt has proved to be very useful and necessary. Turnips, mangelwurzels, and beetroot. Salt for gardens and orchards. Salt as a potato manure. Potatoes, cabbage, carrots. Save the ammonia by salting manure heaps.

Salt and Nightsoil.—Where nightsoil or house refuse is used as manure, it should always be mixed with Salt, which destroys any organic life therein, and by chemical action makes the manure more valuable. And from the other pamphlet:—

GARDENS.—Salt is useful to Gardeners in many respects, and when used with judgment its effects are often surprising. Light sandy soils require more salt than heavy loams and clays. For gardens infested with wireworms a good dressing of salt in autumn will effectually disperse this plague. Potato disease may often be prevented by mixing salt with the manure, or by salting the soil a week or two before planting. For celery a thin layer down the centre of the trench between the plants keeps them moist during dry weather and improves the growth. For onion beds a little sprinkled between the rows, not touching the bulbs, is of advantage. It is most essential to give asparagus beds a liberal top dressing in early spring, followed by a lighter application later on. Spakale beds should also be dressed with salt. Salt is also beneficial to fruit trees, especially Peach, Cherry and Apple. These remarks also apply to flowers, as many practical gardeners recommend salt for the Stock, Hyacinth, Amaryllis, Iris, Anemone, Colchicum, Narcissus, and Ranunculus, &c. As a

rule the best method of application is to use very weak solutions of salt and water. A little salt in the artificial compost used for potting flowering plants, is found to enhance the bloom and brilliancy of the flower.

SALTING MANURE HEAPS.—Horsekeepers and gardeners will find salt most useful for their manure heaps in destroying vermin and in preventing too rapid fermentation and the consequent escape of ammonia.

WEEDS.—To destroy weeds in pavements and garden walks, make a strong brine with salt and boiling water. Apply with a watering can. A moderate quantity of salt stimulates the growth of all vegetation. It is therefore a mistake to suppose that a sprinkling of salt will exterminate weeds.

PLANTING NOTES.

TEA IN THE CAUCASUS.—Reports from Odessa states that the new tea plantations at Chakia, in the Osurgentski Government, on the Caucasus, have given most excellent results, and encouraged their proprietors to engage a number of Chinese experts to instruct the natives in all the intricacies of tea growing. The last tea crop yielded $\frac{1}{2}$ lb. of tea for every bush planted, or 1,500 lb. from an acre having 6,000 tea plants on it. The whole available area for tea growing is 20,000 acres, therefore the total yield could with ease be brought up to nearly 30,000,000 lb. which represents more than half of the annual consumption of the tea imported into Russia. This news is not gratifying to those who expect an expansion of the Ceylon tea trade with Russia, but it is no doubt unduly sanguine in its estimate of future results.

CANAL SILT AS MANURE.—We learn from an Indian paper that Dr. J. W. Leather has been making some interesting investigations into the value of canal silt as a fertiliser, and he comes to the conclusion that the amount of silt and its contents of nitrogen and phosphoric acid are very small during the cold weather, and quite insufficient to replace the plant food taken from the soil by a crop of wheat. On the other hand, the silt carried on to the land during the monsoon period contains very material quantities of these plant foods. They are probably fully sufficient to replenish the amounts of plant food which are taken from the land by the rice crop. According to Dr. Leather's analyses, some 32 lb. of nitrogen and 42 lb. of phosphoric acid were supplied per acre by canal silt in the latter period, as against 8 lb. and 20 lb. respectively in the cold weather.

"THE QUEENSLAND AGRICULTURAL JOURNAL."—Issued by direction of the Hon. A. J. Tynne M.L.C., Secretary for Agriculture Volume I. Part 2. August, 1897. Contents:—Agriculture—The Agricultural Possibilities of Western Queensland, H. A. Tardent; Maize-growing on Scrub Lands, A. J. Boyd; The Velvet Bean; Dairying—Choosing and Breeding Dairy Cattle, John Mahon; On the Development of a Dairy Breed from our Native Cattle, P. R. Gordon; The Tick Pest; The Orchard—Fruit Culture in Queensland, Albert H. Benson; Co-operation in Marketing Fruit; Grape Fruit; Show Awards; Entomology—Scale Insects, Coccidæ, Hy. Tryon; Apiculture—Bee-keeping for Extracted Honey—Part II., H. Stephens; A Tropical Industry—India-rubber (Caoutchouc)—Part I., E. Cowley; The Divi Divi Tree, E. Cowley; Chemistry—Composition of Foods, J. C. Brünlich; The Farmers' Conference at the Gatton Agricultural College; The Fruit growers' Conference; Opening of the Agricultural College; Exhibits of the Department of Agriculture at the International Exhibition, Brisbane, 1897; General Notes; The Markets; Farm and Garden Notes for August; Field and Garden Notes for Tropical Queensland; Orchard Notes for August; Oranges.

CYLON TEA IN AMERICA.—We direct attention to the interesting extracts from Mr. Wm. Mackenzie's letter on this subject. Clearly a good hold has been got on the attention of both the Press and large tea houses in the United States, and this is mainly due to the interest fostered among the consumers. A very good answer to those who go on exalting "Chinas" and "Japans" and depreciate machine-made teas, should be to enquire how, as patriotic Americans, they regard the tea produced by Dr. Shepard in South Carolina. They cannot deny its purity and value, and it will be found, on examination, to be of the same type as our Ceylon teas, though scarcely so delicate as our medium and especially high-grown. Our Tea Commissioner may well take courage and go on with his advertising, whether in verse or prose, in the United States as well as Canada.

COFFEE IN BRITISH GUIANA.—Mr. Thos. Garnett writes in *Tincheri* to correct the prevalent notion that coffee is being grown there for the first time:—

We are solemnly told—quite as a discovery—that the cultivation of Coffee on the already mentioned and misnamed *coast lands* is "perfectly practicable." Now, considering that Coffee was the principal product of this Colony before sugar was ever started here, and as one only has to refer to the annals of the Colony to see how largely it was grown in the No. 1 Canal and other suitable *river districts*, this information is indeed wonderful, and is about on a par with the strange dissertations that have been appearing lately in the local press on the subject of Coffee growing in this Colony. Why my father remembers that little property called "Java," on Canal No. 1—which at the time was entirely in Creole ("Arabian") Coffee—changing hands with only a handful of slaves, for £30,000! I myself have been growing both Liberian and Creole Coffee in the Canal District for a considerable number of years, and as Messrs. Lewis & Peatt's report on my sample appears to have led some people to think that this is the first time Liberian coffee grown here has been sent to England, I may mention that I have been shipping the same to London off and on now for some years, and my shipments have been very ably disposed of, at prices more satisfactory than those now quoted by Messrs. Lewis & Peatt.

THE ABOLITION OF THE TEA DUTY, if effected in Belgium, will have important results says the *Pioneer*—to the advantage of planters in India and Ceylon. It will encourage the use of tea as a beverage, and experience shows that the taste once acquired is retained and spreads by example. As yet Russia is the only country in Continental Europe where tea drinking is general, but the custom is becoming common in France, where, however, as elsewhere tea is heavily taxed. More important than any fillip to consumption in Belgium resulting from the abolition of the duty, will be the effect of that step in strengthening the cause of those who are agitating for the abolition or reduction of the duty in England, and it is not likely that the Chancellor of the Exchequer will be able to resist their demand if he gets many more big surpluses. The advocates of "a free breakfast-table," like the income-tax payers, have been mortified of late years by seeing surplus after surplus allowed up by the navy, military works, education and the landlords, while the voice of Ireland, always crying "Give, give," is to be appeased by a bountiful dole next year. Their time seems long in coming, but it will arrive in the end. Tea has become a necessary of life at Home, and a tax of thirty-five per cent. of its value cannot be defended a day after the possibility of relief.

THE "AGRICULTURAL GAZETTE" OF NEW SOUTH WALES, issued by direction of the Hon. Sydney Smith, M.P., Secretary for Mines and Agriculture Vol. VIII. Part 8. Edited by W. H. Clarke, August, 1897. Contents:—Useful Australian Plants, J. H. Maiden; No. 40—The Mulga (*Acacia aneura*, F.v.M.) A Fodder Plant; No. 41—Salt-grass (*Distichlis maritima*, Rafin); No. 42—A Mud-grass (*Chenaraphis paradava*, Poir); Botanical Notes; The "Brush" of Wheat Grain, N. A. Cobb; Coccids (Scale Insects) in Sydney Gardens, W. W. Froggatt; Magpies (Black and Gray), Dr. Jas. Norton; Destruction of Rabbits by means of the Microbes of Chicken-Cholera, C. J. Pound; The Fodder Value of Salt-bush, F. B. Guthrie; A Gall-making Diapsid, C. Fuller; The Influence of Bees on Crop, A. Gale; Bee Calendar for September, A. Gale; Orchard Notes for September, G. Waters; Practical Vegetable and Flower Growing for September, W. S. Campbell; General Notes; Replies to Correspondents; List of Agricultural Societies' Shows; Label for Specimens.

PLANTING IN BRAZIL.—Mr. T. L. Villiers, formerly of the Scrubs, Nuwara Eliya, who has just returned to the island with Mrs. Villiers, has come to the conclusion that there are worse places than Ceylon to plant in. It will be remembered that he was engaged by the Directors of the Dumont Coffee Company to take charge of the large and recently-acquired property of the Company in Brazil. Mr. Villiers went with Mrs. Villiers to the estate, but found the life there rougher than he anticipated, and very different to a planter's life in Ceylon. The heat, he says, was very trying, almost as bad as Colombo, and yellow fever was very prevalent in the neighbourhood, so that he managed to get his agreement with the Company cancelled, and left Brazil after a very brief stay. His description of planting life in Brazil is interesting. There are very few English in the country, and they are not popular with the indigenous population. There was a European family on the Dumont Company's property—the Secretary and his wife—but the nearest European doctor was a 16 hours' railway journey away, and the labourer is Italian, with little in common either with the cooly or with the planter. The little narrow-gauge railway that traverses the San Paulo district is the principal means of communication, but there is an accident on it nearly every day, so that, while it is useful for freight, passengers prefer to go round to Rio by sea, as being slower but safer. Brazil coffee growing may be profitable, but is evidently not an occupation for a married Ceylon planter, or for anybody who is not prepared to rough it a good deal. Mr. Villiers has gone up-country, and may be reckoned once again as a Ceylon planter.—Local "Times."

A NEW MIXTURE.—Adulterated tea is played out in these markets. The use of the Indian and Ceylon tea industries practically put an end to the art of doctoring tea leaves. On the Continent the game still flourishes, and a preparation of adulterated tea-leaves is described in a German medical paper. The preparation has long been known in Russia, where it is sold under the name of "rogogeski." It is made in the following way:—"The manufacturers of this adulterate buy in the tea houses the residue of the teapots—leaves which have already been used—and mix these leaves while still moist with other leaves and very little genuine tea. The mixture is heated with an addition of extract of caramel and campeche wood, in order to improve the colour and the taste. The weight is also increased by the addition of sand or soil, and just before being dried the leaves are rolled between the hands. The adulteration is so difficult to recognise, that a chemical test is necessary to prove it. If tea prepared in this way is dipped into a cold saturated solution of copper the blue colour of the solution will not be changed, not even if the adulterated tea is allowed to remain in it for three or four months. If the tea is fresh and has not previously been soaked, the solution will turn green within a short time."

SUNFLOWER SALAD OIL.—Dr. Wiley, the chemist of the Agricultural Department in Washington, says that in his opinion the coming salad oil will be made of sunflower seed. It is a perfect substitute for olive oil, and will be very cheap.—*American Agriculturist*

ACACIA SEED.—There is quite a dearth of Acacia seed this year in New South Wales—two leading "Seedsmen" firms reporting that the dry season has stopped the trees from seeding. Another firm reports that the only Acacias available, are:—"Acacia Pynantha" S. A. Wattle for Bark. "Acacia Decurrens" N. S. W. Wattle Bark.

THE "INDIAN FORESTER."—Edited by J. Olivier, Conservator of Forests, and Director of the Forest School, Dehra Dûu. Contents for September, 1897:—Original Articles and Translations: Sir Richard Strachey and Indian Forestry by Sir Dietrich Brandis, K.C.D.E., PH.D., LL.D., F.R.S. Correspondence. Esparto Grass, Letter from "Q"; Forest Literature, Letter from "Miles"; Calotropis procera, Letter G. M. R. Reviews: Mathiev's Flore Forestière, Forestry in the Central Provinces during 1895-6, Forest Administration in the Southern and Sind Circles of Bombay during 1895-6. Extracts, Notes and Queries: Timber and Produce Trade Extracts from Official Gazette Appendix Series: Planting up of Shifting Sands near Dresden in Saxony, by A. M. Reuther, Indian Forest Service.

RUBBER AND CEYLON.—The Editor of *The India Rubber World* evidently thinks Ceylon may do for "rubber" what was done for "Cinchona" in a big production! We quote as follows:—

The new director of the royal botanic gardens of Ceylon—Mr. John C. Willis—is a believer in the cultivation of India-rubber as practicable at least for that part of the world. His initial report, recently published, has won high praise from the usually critical *Tropical Agriculturist*, of Colombo. While not underrating the value of the purely scientific work in botany performed by Mr. Willis's predecessors, the *Agriculturist* is pleased at the evident disposition of the new director to devote his attention to the more practical department of economic botany. The most important steps in rubber-cultivation now under way are being taken in Ceylon, where the new director of the royal botanic gardens is addressing himself to the task enthusiastically, in the belief that results of great value are attainable. It is not impossible that his hopes may be grounded on reason. While Mr. Gustav Mann's long experience in Assam led him to discourage all planting of exotic rubber species, the pioneer introducer of Pará rubber-trees into India—Sir Clements Markham—has recorded in *The India Rubber World* his belief that, if the initial attempts had been seconded with proper vigor, that country would now be an important producer of Pará rubber. But supposing Mr. Mann to be entirely right with regard to the localities in which he worked, it may be that Mr. Willis has found in Ceylon exceptionally favorable circumstances, and that the hundreds of planters who in that island are seeding Pará rubber alongside their tea estates may derive a profit therefrom as promptly as the last generation did from their first plantings of tea. Though we Americans are little tempted to invest in rubber plantations under any conditions, we may watch with interest the development so confidently predicted in Ceylon, remembering that we, no less than the rest of the world, have profited from the enterprise shown by the English colonists there for more than a third of a century in the growing of cinchona.

Renewed attention will be called to the subject by the papers laid on the Council table recently which we reproduce on another page and notice.

"HOW TO ECONOMISE THE AVAILABLE LABOUR SUPPLY ON OUR TEA PLANTATIONS."

REVIEW OF LETTERS LIV. TO LXII.

The nine letters to be dealt with at present do not occupy as much space as the batch immediately preceding; but they are full of interest nevertheless. "Old Planter," from a Mid-District, adds his own testimony to that of the many experienced men whose letters we have already noticed in favour of wire shoots, as a great labour-saving appliance, whose use should be extended for the transport of both leaf and fuel. In this opinion "T." from a High District concurs; for, although he has had no practical experience of them himself, he has seen them at work. "C.H." has used shoots for firewood, and thinks they might be used a good deal even in the lowcountry, whence he writes. Narrow cart roads for half carts he is in favour of for large estates, but like the two previous writers he doubts whether tramways could be laid down and worked at a reasonable cost. "F.J.H." from a Medium District testifies to the great saving in labour, shoots effect, while doing little injury to leaf; and so does "O.C." from a High District; but "B.", also from a High District, has evidently had unpleasant experience, as he says much care is necessary to avert damage to leaf. "J.N." from a High District, who has had experience with both shoots and wire tramways on Humasgiriya, approves of them for firewood; but would prefer wire tramways for leaf, as he thinks shoots would bruise the leaf. Planters, however, who have worked shoots have been able to reduce damage to a minimum; and "Thirty-three years at it," in a High District, cannot see any reason for damage if the shoots be not too steep; and even then a check cord can be used. "W.S." from a Medium District, while admitting some damage from too great length and steepness of shoots, believes that they can be more largely used. Only in very exceptional cases are tramways considered feasible on estates by our correspondents; but "Old Planter" starts a new theory in suggesting as a labour-saving device, the sending down of all tea, "in special chests made for the purpose," in good stout paper, so that all final firing and packing might be done in Colombo. Even assuming that the Colombo charges will not swallow up the saving anticipated in transport of lead, nails and hoop iron, lessened by the original cost of the special chests and their transport, will planters accept Colombo firing and packing, including perhaps bulking, as a substitute for factory work done under their own eyes? The objection will not, of course, hold except in the case of proprietary planters: but the saving in transport, it strikes us if other objections are overcome, is likely to prove a more important factor than any convenience arising from the saving of labour on Estates. We fear though that experiments already made in this direction have not given satisfactory results.

On the question of weeding, conservatism continues to be the most prominent feature. "Old Planter" declares that there is nothing like clean weeding; and that if a rupee per acre per mensem is paid, the charge might be reduced to 50 cents when the tea covers the ground and

pluckers have to go their rounds once in eight days, and thus help to keep down the weeds. Small ferns and mosses are not objected to by this writer, who further recommends the closer planting of tea (two plants in each hole 18 inches apart) as an aid to the prevention of wash, and also the planting of grevilleas, whose leaves serve as mulch and do a lot of good, especially in thin tea with a large percentage of vacancies. "T," too, expresses his preference for the present system of monthly weeding which, with the present system of manuring, would scarcely give time for mosses and ferns to grow. "C.H." inclines to the same view, though he allows that selected weeding might do good. "B" is emphatic that weeding has not been overdone, though scraping has been; and "J.N." believes in the present system, as having the further advantage of satisfying the kangany and keeping the labour force together, though Indian planters have remarked that weeding is overdone. "Thirty years at it" also gives the weight of his experience in favour of weeding clean, when it can be done under a rupee; while for dirty estates he recommends the taking out of coarse weeds, and the stirring up of the soil once a year to break the hardening surface. So also with "W.S." who thinks weeding has been overdone only when the hoe has been in constant use. The hoe and the karandy he would dispense with, and use "kootlie" instead; but "F.J.H." asserts that weeding is often overdone, and justifies the system on the ground that occasional weeding is very expensive, as our weeds grow all the year round, while in India they give no trouble from October to March. "O.C." while conceding that weeding may be overdone here, objects that kangany will not stay on estates without weeding contracts. Does not this frequent reference to the kangany imply that he is gaining too much influence? Certainly humour him reasonably; and if the present system of weeding is maintained chiefly to propitiate him by enabling him to supplement his income from head money, he should not have the further privilege of practically unlimited "cost advances."

The present system of draining, generally approves itself to most correspondents, some of whom suggest slight modifications, while some would have the drains cut closer. Probably a goodly number of estates answer this requirement, and the writers express only the deficiencies of their own particular charge. "J.N."s suggestion of a large pit or dam to catch the wash is one which it would not be easy to adopt on most places; but where it can be provided, it should be useful in catching something more than the silt.

We have noticed the importance which older planters attach to personal relations with the cooly, combining firmness and kindness, task work, bonuses for extras, &c. In the batch of letters under notice too, similar suggestions occur; but "J.N." starts a new remedy in a new Labour Ordinance better suited to Tea than Coffee. We are not sure whether all that is needed may not be found in the existing Ordinances; and before longer terms of agreements are asked for, may not we inquire whether contracts are in force for three years, and have been found to be insufficient? There is a general disinclination for new legislation, which has always to be referred to the Indian Government for their consideration and approval.—The remarks on Bazaars and Arrack call for no special comment.

(Letters Continued.)
No. LXIII.

1. Yes, I have used them and find them a great saving of labour both for transport of leaf and firewood.
3. Yes, I should think so.
4. No.
5. No.
6. No.
7. I think that as a rule drains are cut at too steep a gradient. If they were cut at an easy gradient, the soil would be suuk in them and thrown out round the tea bushes when the drains were cleared out.
8. None that I know of.
9. I think most estates give the coolies land for gardens.
10. In moderation.
11. No.

D.

No. LXIV.—HIGH DISTRICT.

1. Yes, have had a large experience of wire shoots (have worked five shoots myself; and there have been nine shoots on the three estates on which I have served, and I have seen six others working on various estates). In this district I know of and have seen five shoots now being worked for leaf transport, and some of them for firewood. I have a shoot $1\frac{1}{4}$ mile long on my present charge, and another shoot, $\frac{3}{4}$ mile long, also comes from a neighbour's estate to my factory for leaf transport. They do not damage the leaf: provided a sufficient supply of mana grass, or other soft substance, is heaped at the bottom of the shoot, to act as a buffer. I believe wire shoots are in general use where the lay of land admits of them, as a saving in transport by coolies.

2. Endless tramways might be more generally used for transport by groups of estates in hilly steep districts. For instance an endless tramway from Padupolala to the top of Kurunduoya or High Forest, could be made to serve Alma, Greymont, Seaton, Kurunduoya, Rillamulla, Bramley, Lauriston, High Forest: for the down transport of tea, boxes of tea, and the up transport of manure, tea requisites, rice, &c. Such tramways are used on the Glen Alpine, Rock Hill, and Spring Valley estates for manure transport. Where tramways are not compatible with the lay of the land, tavalams might be used for tea transport, but the boxes would have to be made narrower and longer; this has, I believe, been tried on Dehigolla estate.

3. Not on ordinary estate roads: they might be on cart roads, or roads of a good gradient.

4. Yes. I feel sure it is overdone.
5. Yes.
6. No. I would like to see the experiment tried.
7. Fairly so. Large holes might be cut at intervals along the drains to catch soil washed into it, and this soil might be afterwards distributed over the adjoining ground, as each hole fills up. Thus:—

The cuscus grass idea seems very good.

8. Telephones between factories and bungalows often save coolies as messengers. District tapal coolies would be another saving, or one tapal cooly to each group of estates,

9. Plenty of ground for gardens, the allowing of coolies to keep cows and pigs, and goats; all tend to make them contented (gardens especially).

10. Yes! Strongly.

11. Yes! Liquor shops ought to be done away with. D. E.

No. LXV.

1. Yes, I think wire shoots could be advantageously used much more largely for transport of fuel and leaf. The leaf is not injured by being sent down by a shoot.

2. The widening of existing roads, where practicable, to admit of single bullock carts being used, saves cooly labour to some extent.

3. I have no experience of small tramways and do not know what they would cost per mile.

4. I have never thought that small weeds do the least harm to either tea or coffee and they undoubtedly save wash. But it is cheaper and takes less labour to keep an estate quite clean than to allow small weeds to grow. Otherwise I think it would be better to leave them. Mosses should certainly be left to grow.

6. No, nor do I think it would answer.

7. Terracing was largely carried out on Delta and other old coffee estates, and did some good. But I do not think anything will stop the wash on the steep hills of Ceylon after the land is once cleared.

8. I know of none that would answer, beyond doing as much as possible by machinery in the factory and transporting by cart roads and wire shoots wherever practicable.

9. Coolies should certainly be allowed small gardens and they are on most estates. They should be always supplied with good rice and always of the same quality as far as possible. Large advances make coolies more unsettled than anything else.

10. I think multiplying boutiques might do some good and this is being done in several places. But I expect most of the coolies would always go to the large bazaars on Sundays.

11. The number of liquor shops, should be reduced as much as possible, and it is not altogether desirable that the monopoly of selling liquor should be in the hands of a very few, as they would sell poisonous stuff at extortionate prices. Coolies will go a long distance to get liquor, but numerous liquor shops, of course, increase the temptation to drink.

MERCHANT PLANTER.

No. LXVI.—MEDIUM DISTRICT.

I have your circular on "How to economise the available Labour Supply."

The Labour Supply in most districts is now ample for all requirements; in districts where it is not, I would suggest a little more honesty in all dealings in connection with labour, and an honest endeavour to procure coolies from the coast; they, coolies, are to be procured; but so long as planters encourage the present buying and selling of coolies, and wink at all kinds of malpractices, districts that are short of labour will continue so.

Labour appears to be coming in from the coast very freely this year. [Written some time ago.—Ed.]

To those who will give up trafficking with the labour force of their neighbours and other districts, and who will honestly attempt to get fresh labour from the coast, I believe that the present is a very favourable opportunity.

I don't care to offer an opinion about working, etc.

Keeping Coolies.—The man who can get coolies, can keep them. The man who finds difficulty in getting them, cannot. Coolies know very well when they are well treated and want no bribes to stop; where they are badly treated no bribe will keep them. G.

No. LXVII.

Was your circular of 20th instant sent to me as a joke? I am afraid I can't throw much, or any, light on the subjects regarding which opinion is asked,

If you had asked me for an essay on the present troubles attending the working of the Labour Ordinance I would have been more pleased!

With respect to suggestions as to keeping labour, I found, in working my places in Badulla, that the giving of ground for gardens to each of the lines attracted and kept coolies. Another attraction to them was the great number of jak and arecanut trees I had on Brechin, by the stems of which I encouraged the coolies to plant betel vines. I was never hard-up for labor on Brechin; but those times have changed; heavy advances were unknown then.

I don't know that the multiplication of bazaars in the neighbourhood of estates, is an unmixed blessing. Still the coolies undoubtedly appreciate the convenience of a nearness of bazaars whence they can get their provisions.

What my opinion is about liquor shops, I have endeavoured to embody in the report of the Sub-Committee P.A., on the arrack question, of which I was a member. I am strongly of opinion that liquor-shops should be lessened in the country; at the same time it is undoubtedly true that arrack, fairly pure, is sold in taverns; while it is an ascertained fact that vile adulteration comes in when the arrack is illicitly sold. It is a matter for much regret that kanganies themselves illicitly retail arrack *in the very lines* to the coolies. So that the close proximity of liquor shops really makes no difference—if any, it is rather favourable to the cooly who gets purer stuff to drink. These are my crude ideas—next time, ask me something about Law or Procedure!

LAWYER-PLANTER.

LXVIII.

(By an Old Planter.)

Aberdeen, Sept. 15th, 1897.

From the papers to hand by last mail, I see you are still putting questions to your Upcountry friends; permit me to answer from this distance, although it may be somewhat late in the day for publication.

No. 1. Yes, for transporting fuel, but not for leaf. Certainly, they might be more freely used than they now are. In some of the places of amusement in England, they are a great source of amusement as a means of getting from one place to another, simply by hanging to the hook attached to the pulley. The travellers did not seem to have the slightest fear of any accident: even two went along the shoot, hanging from the same pulley. You may yet hear of shoots being connected to the factory from the bungalow on some estates, as being the quickest and safest way of getting to the factory!

No. 2. In the field, by the use of saws, when they can be used, instead of employing axes for cutting fuel, also all the best tea machinery required including a tea-packer and circular-saw. Under this heading might be included the chests made by the Acme Tea Company, as they are far more easily put together than wooden chests.

No. 3. On an estate of an easy lay of land, tramways might be laid to be worked profitably, but hand-carts costing less, or even light bullock-carts would meet all the requirements equally well.

No. 4, 5, and 6. No, certainly not; weeding three times in two months is preferable in my opinion to once a month, and it is the best and cheapest way of tackling a weedy estate and keeping it clean. I look on a plant out of place as a weed, and prefer a clean estate.

No. 7. The present system I consider very satisfactory, and an improvement on the old coffee-day system, inasmuch as, that the drains are generally closer than they were then.

No. 8. If leaf be weighed only twice daily, try three times a day for a month, and, instead of having a staff of men spreading leaf in the factory, make the leaf carriers always spread their own leaf. It has been found that with a man looking after them, the work is quicker, and ought soon to be equally well done, and at less cost.

No. 9. Perquisites are always acceptable to coolies, and from their birth onwards, they are always in need

of any thing master is pleased to give; special needs are constantly arising, from the time the cooly enters the world till he leaves it. Estates having cattle establishments with plenty of milk to give to the young children, and the sick, are always favourite estates with coolies; also where land is allowed near lines suitable for cooly-gardens. These gardens may not always be well kept, but a good cooly likes his garden and will often be seen working it on Sundays and till late on week nights. Coolies, the so-called owners of gardens, are not so easily enticed to leave an estate as coolies are who have no gardens. Supplying coolies with cloths and cumbies direct, and charging them to their accounts is preferable to their buying them in the bazaar.

No. 10. I believe in allowing a few boutiques to be on a large estate, and a small kaddai for the sale of curry stuffs, etc., in a room of the lines on a small one.

No. 11. The illicit sale of drink (arrack) and especially *toddy* does more towards demoralizing the cooly, than even the indiscriminate issuing of so-called, coast advances.—Yours truly,
J. W.

[This concludes the discussion raised by our Circular on "how to economise the available labour supply," and we have to thank the several correspondents who have answered our questions; the whole discussion will be reprinted in pamphlet form. —ED T.A.]

FINAL REVIEW—LETTERS LXIII. TO LXVIII.

Our task now is to offer our final comments on the last six letters of the series, and a pleasant duty it is, equally in view of the prospect of finality to our labour in this direction, and because of the value of the information we have been able to bring together, through the courtesy and powers of observation of so many planting friends. To deal, however, with the letters immediately before us: first, "D." informs us in the briefest possible terms that he has had experience of wire shoots and has found them a great saving of labour in the transport of both leaf and and firewood; that he thinks tramways should be useful, that weeding is not overdone, and that he is not favourable to any crop being grown to be dug in; that drains as a rule are cut too steep, and that an easy gradient would render the soil available for the adjacent tea bushes; that he is a believer in bazaars in moderation, but not in liquor! "D.E." from a High District claims extensive and varied experience with shoots himself, and has seen them at work on other estates: he has one on his present charge $1\frac{1}{2}$ mile long, and another of $\frac{3}{4}$ mile brings leaf to his factory from a neighbouring estate; and his verdict is that leaf is not damaged where a buffer of mana grass or other soft substance is provided, while shoots undoubtedly save labour. Endless tramways, he thinks, might be more largely used, and he instances the facilities to a large number of estates which one from Padupolala to the top of Kurunduo-ya or High Forest would afford, for fetching up rice, manure and tea requisites, and sending down tea and tea boxes. Such tramways have, in point of fact, passed the experimental stage for manure transport on the Glen Alpine, Rock Hill and Spring Valley estates; but where the lay of the land does not favour these wire tramways, tavalams are recommended for tea transport in narrower and longer boxes than are now in use, and which have been tried on Deligolla. Ground tramways are voted unsuitable on ordinary estate roads,

“Merchant-Planter” shares the opinion that shoots might be more largely used for fuel, as well as for leaf which is not injured in transport with care; and, while disclaiming knowledge of tramways, he advocates the widening of existing roads for single bullock carts as a means of saving transport labour. “G.” from a medium district brushes off our questions as evidently altogether out-of-date. The labour supply in most districts, in his view, being ample for all requirements, the need of economizing labour does not seem to him to arise. Where labour is wanting, honest dealing will secure it; and the present is regarded as a good time for men turning over a new leaf—not the leaf in regard to the transport of which other planters are exercised—and placing the Indian labour centres under contribution honestly for an adequate supply. Having persuaded himself of the general sufficiency of labour, and prescribed the best way of securing a supply in the exceptional circumstances in which it may be insufficient, “G.” feels that those who can get coolies can keep them, through the recognised agency of good treatment, and he declines to offer any opinion about working. The conclusion whereof is, that “G.” is a happy man with his labour, save when a crimp is about, at sight or sniff of whom he waxes grumpy; and that he wants neither to learn more than he knows, nor to teach those who may wish to know, you know! “Lawyer Planter,” is somewhat of “G.’s” way of thinking; for he would much rather have been asked for an essay on labour troubles, on which he would seem to hold strong views, than for suggestions on the utilization and economizing of the existing labour force. “J. W.,” however, although in far-off Aberdeen, has been carefully following the discussion in our columns, and he votes for the more extensive use of shoots, but not for leaf. In the absence of the unmanufactured leaf in England, the people there are manufacturing amusement out of shoots, by hanging on to the hook attached to the pulley, and transporting themselves from one place to another (presumably terrestrial); and from the safe distance of the granite city he contemplates the possibility of providing for rapid locomotion from bungalow to factory! Whether the general adoption of the suggestion may not lead to a reduction in the extravagant rates now charged by Insurance Companies on planting lives, is a question we should like to see discussed! Though tramways may be laid and worked profitably on an easy lay of land, “J. W.” believes that hand carts and light bullock carts should meet all requirements equally well at a smaller cost; and he also advocates the use of saws, instead of axes for cutting fuel; the use of the best tea-machinery, including a packer; and also acmè chests, as a means of saving labour.

On the question of Weeding, “D. E.” feels sure that weeding is overdone, and that selected weeding might be adopted, as also experiments with green crops to be dug in; while he favours us with a sketch showing how soil pits in side-drains and at the foot of the main ravines might conserve soil to be applied to the fields at each clearing out. Cusens he welcomes as a good idea; he would have telephones between bungalow and factory to save coolies as messengers, and also a district tappal cooly, or a cooly for each group of estates; he would give plenty of ground for gardens, and allow goats, pigs and cattle to be kept by coolies; he would have more bazaars and do away altogether with liquor shops.

“Merchant-Planter” recognises the impossibility of doing more than reducing liquor shops; but he would not create a monopoly which would lead to the sale of bad liquor and exorbitant prices: on the other hand, he would multiply boutiques. In addition to humouring coolies with gardens, he would give them good rice, of fairly even quality. While always holding that small weeds could never do harm either to tea or coffee, at the same time that they prevent wash, he regards it cheaper and a greater economy of labour to keep an estate quite clean than to allow small weeds to grow; but mosses he would let alone. Terracing is useful, but wash is inevitable on cultivated hill sides. “Lawyer-Planter’s” experience of jak and arcanut trees for their own sakes, and as supports for betel vines, as inducements to coolies, is interesting; and while he thinks that the multiplication of boutiques is not an unmixed blessing, he holds strong views on the mischief done by arrack especially when illicitly sold, as it is athen impure, and when ganics are in kau the illicit trade. “J. W.” holds strongly that weeding is not overdone, and he would even weed thrice in two months, as cheaper than monthly weeding; the present system of drainage has his approval as an improvement on that of the old coffee days when the drains were wider apart; he would save labour by making the leaf carriers spread the leaf in the factory, and by weighing the leaf thrice a day; and he would humour the coolies with garden patches which help to keep them on an estate, together with small perquisites; he would allow a few boutiques on a large estate, and would check the illicit sale of arrack and toddy, as more demoralizing even than so-called coast advances.

These, then, briefly are the substance of the final batch of letters and our comments on them; and it may be well to indicate, in a few words, the impression left on our minds by the series of letters as a whole which our circular elicited:—(1) Tramways are unsuited to most estates, and their initial cost stands in the way of their use, except under very exceptional circumstances. (2) Wire tramways are doing good work on the few places on which they have been erected, and their extended use should follow the high appreciation of them which our circular has elicited. (3.) Wire shoots are in tolerably extensive use; and their use is likely to spread, through the removal of the prejudice against them for the transport of leaf, on the strength of the testimony of experienced planters who have reduced the damage to leaf to a minimum by the exercise of ordinary care. (4.) Among other labour-saving appliances must be included roads, carts, telephones, up-to-date machinery and a well ordered Factory—all directed by strict, yet considerate oversight. (5.) The great majority of planters prefer clean weeding, partly on the principle that what is, must be best, and, partly, because the kangany must be propitiated, and weeding contracts have been his immemorial and most welcome perquisite; but a few who are not afraid to tackle a new difficulty are experimenting with water holes and selected weeding, as a means of reducing wash and conserving the soil-constituents. (6.) The principle is sound of the system of drainage; but modifications, called for by local circumstances, should be more readily adopted. (7.) The multiplication of boutiques carries with it risks of theft of produce, illicit sale of arrack, and growing indebtedness. (8.) Arrack Taverns

and Liquorshops are an evil; but they are the lesser of two evils; as, in their absence, illicit traffic is inevitable. (9) Just, firm treatment of the cooly is the great panacea for labour troubles and discontent; and to secure this, the master must be in touch with his men, sympathise with them, and not be too often absent from the estate, whether on pleasure or business.

PROGRESS IN THE STRAITS.

From a Report by the Commissioner of Lands and Mines, F.M.S., dated Kuala Lumpur, 12th August, published in the *Negri Sembilan Government Gazette* of Oct. 15th, we quote a few passages of planting interest:—

After driving for some thirteen miles, from Seremban, through a succession of coffee estates—all except one of which are in the hands of European owners, and the healthy growth of which, notably in the case of the older plantations superintended by Mr. Dunman, is a pleasing augury of future success—we exchanged the dogcart for our horses, and rode for another thirteen miles on a track running through continuous kampong and sawah land to Cheong, where we halted for a midday rest.

The country lying between Kuala Pilah and the foot of the hill is at least as noticeable for picturesque scenery and continuous cultivation as any which we passed through during the course of our tour. The long valley by the side of which the road runs is one extensive padi field, and every little valley which diverges from it is utilised for the same purpose. The higher lands which fringe the valley have evidently been under cultivation for a large number of years, the fruit trees being for the most part mature, and, in many instances, of grand proportions.

I have seen stretches of country in other parts of the Native States exhibiting the same features of valleys emerging from among the spurs of the hills, and alternating with higher and undulating ground, but never have I seen any attempt to form those valleys into padi fields in a manner or to an extent which will bear even momentary comparison with what is regularly done in the Negri Sembilan. These States are not naturally more productive than other places. What has been done there can be done elsewhere, and for some considerable period in the future the States of the Negri Sembilan (old) will stand as an example of what can and should be done for the land by the native agriculturist.

Then from Report of the District Officer, Tampin for July, 1897.

On the 22nd we left Kuala Gemenchah, at 7:30 p.m., and walked over the footpath to Kelamah Tapioca Estate and thence to another estate at Chembul. The distance walked was about 20 miles, and the journey occupied the whole day. Between Kuala Gemenchah and Kelamah, at a place called Ladang, there is a beautiful expanse of padi country, at present abandoned; I trust, however, it may ere long be brought into cultivation again by a scheme which I have proposed in a separate communication.

At Kelamah the managing partner of the estate, Li Kah, met us, and accompanied us to Chembul, where we stayed the night at a very nice little house erected by Li Kah for his own use. Li Kah, who manages both Kelamah and Chembul Estates, complained that owing to the bad state of the Malacca roads he had hitherto been unable to export much of his tapioca and had 1,000 bags at Chembul and 2,000 at Kelamah awaiting export. As (owing to the dry weather) the state of the roads had improved, he asked assistance to enable him to get these large quantities of tapioca out as soon as possible. I have since detailed a clerk to weigh the tapioca at his factories, with the result that over 2,000 pikuls were weighed and exported during August, bringing in about \$500 duty.

DRUG REPORT.

(From the Chemist and Druggist.)

London, Oct. 7.

The Markets show several interesting features this week. Quinine has been the chief centre of interest. The spice-boom is still raging, but has shifted from white pepper to cloves.

VANILLA.—The following figures are supplied to us as being the "authentic" particulars relating to the Eastern vanilla crops of 1897 and 1896:—

	Place.	Bourbon.	Seychelles.	Mayotte.	Mada-gascar.	Mauritius.
	kilos.	kilos.	kilos.	kilos.	kilos.	kilos.
1896	98,000	25,000	13,000	2,500	2,500	2,500
1897	100,000	13,000	8,000	2,000	2,000	2,000

The total output in 1897 is therefore about 13 per cent less than last year—viz. 125,000 kilos, against 141,000 kilos. In these figures no account is taken of the small production of the West Indies, Ceylon, &c., nor of the large crop of Mexico. The London market remains firm, and a fair amount of business has taken place privately at steady rates since the last auction. It seems likely that prices will keep at their present level until Christmas and New-Year's wants have been filled.

CINCHONA.—The average quinine content of the manufacturing barks at last Thursday's auctions at Amsterdam was the highest on record. Not so very long ago a 5-per cent average was considered a high one; last week it was 6.10 per cent. The richest parcel offered was one of 27 bales le geriana crushed bark, analysing 9.24 per cent. This realised 58c. per ½ kilo. The highest unit paid was 7c., at which 2,126 kilos of bark changed hands, the lowest 3½c., at which 921 kilos sold. The tone was very animated throughout the auctions, and improved steadily towards the end. The general opinion is that a further advance is imminent. Druggists' barks realised irregular but generally higher prices. There was an especially good competition for crushed Succiubra, which was readily brought by cinchonidine manufacturers. The following figures show the result of the first eight Amsterdam auctions (Jan.-Oct.) of the past five years:—

Year.	Total weight of bark offered.	Representing of sulphate of quinine.	Average content of manufacturing bark.	Total weight of quinine sold.	Total weight of quinine bought in.
	kilos.	kilos.	per cent.	kilos.	kilos.
1897	4,005,504	221,008	5.26-5.10	186,444	34,614
1896	4,528,277	240,309	5.05-5.23	202,126	35,183
1895	4,636,869	225,367	4.63-5.17	141,314	81,653
1894	3,443,051	161,619	4.61-5.12	155,757	35,932
1893	3,930,594	172,982	4.23-5.02	97,679	75,303

The exports of cinchona-bark from Maracaibo, S. America in 1896 amounted to 161 cwt.

COCOA-BUTTER.—At auction on Tuesday 200 cwt. cases of Cadbury's best cocoa-butter sold at from 12½ to 13d per lb., being an advance of 2d on the last public sales. For 150 cases of Dutch cocoa-butter a bid of 10½d per lb. was rejected, and the lot was bought in at 11½d per lb. At the Amsterdam public auctions held on Tuesday about 80 tons of Van Houten's cocoa-butter were offered. Of this quantity 23½ tons sold at up to 60c. per half-kilo. The only other parcel sold was one of 7 tons Dutch ("Hammer") cocoa-butter, which realised 55c. per half-kilo. Several lots of different brands were bought in. The market generally is quiet.

KOLA.—The demand has been slightly better recently but London holders have some difficulty in competing at present, Hamburg and Liverpool both offering at lower rates. In the last-named place there seems to be a big stock.

KOLA-NUTS are held for higher prices at last Thursday's auctions. Ordinary slightly mouldy good bright West Indian sold at from 3½d up to 8d per lb., and 19 packages wormy and mouldy African kolas were also disposed of.

ESSENTIAL OILS.—Lemongrass oil is rather dearer, and the cheap lots offering in London at 2½d per oz. have been bought up, and 3d is now asked on the spot. To arrive nothing is offering. Citronella oil steady at 1s 2½d per lb. in tins, and 1s 2d in drums. To arrive the quotation is 1s 1½d per lb. in drums, c. i. f. terms, shipment to end of year.

DEAFNESS. An essay describing a really genuine Cure for Deafness. Ringing in Ears, &c., no matter how severe or long standing, will be sent post free.—Artificial Ear-drums and similar appliances entirely superseded. Address THOMAS KEMPE, VICTORIA CHAMBERS, 19, SOUTHAMPTON BUILDINGS, HOLBORN, LONDON.

PLANTING NOTES.

COFFEE from British Central Africa, says a correspondent of the London *Times*, is fetching higher prices in Cape ports than any of the other kinds usually imported. It is far superior to Java or Rio coffee.

THE MANURING OF TEA.—Writing on the 1st Oct. from London, Mr. John Hughes says:—"Your letter of the 8th Sept. respecting the traffic returns on the railways for manure duly to hand, and I thank you for the explanation. I imagine there is very little increase in the use of manure either for tea or coffee."

STOOLING OF GUTTA PERCHA.—The question whether the tree yielding gutta percha (*Dichopsis Gutta*, Benth.) will produce shoots from the stump after the tree has been felled is of some practical importance. It appears now to have been disposed of in the affirmative:—Extract from letter from Director, Gardens and Forest Department, Singapore, dated July 3rd, 1897. *Re* Professor Ramsay's letter about stooling of "Getah percha." The tree always comes up again when cut down. It can be cut to within six inches of the ground, and will then throw up shoots. Were it not for this there would hardly be a single specimen in this country. It grows slowly in this manner, but never fails to come up again. It is a very troublesome plant to propagate by cuttings, but this can be done.—*Kew Bulletin*.

THE MANGO.—With reference to the suggestion recently made that there should be a demand at home for the Indian mango, the cultivation of which was strongly recommended by Sir George Birdwood, whilst secretary of the Agri-Horticultural Society, it is interesting to find in this connection that the Government of Queensland lately sent an experimental cargo of mangos to London. The fruit was kept at a constant temperature of 45deg Fahrenheit during the voyage, and arrived here in excellent condition. As mangos thrive in the West Indies, no doubt some of the fruit will sooner or later be sent over here from British Guiana and the West India islands.—*H. & C. Mail*, Oct. 8.

GOVERNMENT CINCHONA GARDENS IN JAVA AND INDIA.—The *Chemist and Druggist* of Oct. 2 in discussing the annual report on the Madras Cinchona gardens, remarks:—

It is generally known that, unlike the Java Government gardens, whose bark is sent to Amsterdam to compete in the open market with the barks grown by private firms, the Indian Government do not compete with private traders in Europe. They sell all their product to the Indian Medical Stores, and to native consumers—quinine at 18s., and febrifuge at 16s., per lb. The average yield of the Crown and hybrid barks treated during the year was 3.32 per cent. of quinine and 1.39 per cent. of febrifuge; that of the red bark 4.45 per cent. of febrifuge. The sale of cheap Government quinine and febrifuge to the Indian native population is increasing very slowly. In 1896 it only amounted to some 2,000 lb.—an advance of about 10 per cent. on the previous year. The bulk of these sales takes place through the 1,550 village postmasters in the Presidency, who retail it in 5-gr. packets. The Medical Stores Departments at Bombay, Calcutta, and Madras are the best customers of the gardens. In the course of last year the Madras cinchona department was separated from the botanical department. Mr. David Hooper, the Government Quinologist, was temporarily appointed assistant to Dr. Watt, the Reporter on Economic Products to the Government of India, and he has since been definitely appointed assistant-curator in the Indian Museum at Calcutta. Mr. Stander is therefore now in sole charge of the Nilgiri cinchona-gardens. It is to be hoped that the experiment of appointing a practical planter and businessman instead of an official, which has been attended with so much initial success, will continue to work well in the future.

GREVILLEAS.—They are so taken with the great value of grevilleas in tea, that Ceylon planters are now asking themselves whether, if planted out in their now abandoned coffee, their old favourite might have been saved. For an answer, they need only turn to South India, where the silver oak enjoys enormous popularity.—*Planter*, Oct. 16.

ASCLEPIAS CURASSAVICA AS AN INSECTIFUGE.—The use of this plant for the purposes described in the following communication appears to be unrecorded:—Rostherne, Red Hill Snrey, July 21st, 1897. Miss Manning would be greatly obliged if the Director would tell her what the enclosed plant is. It grows everywhere, as a weed, about the Isthmus of Tehanhtepec (Southern Mexico), and is used by the Indians there to keep away vermin, especially fleas. Miss Manning's friends in Mexico have tried it, and found it most successful. They make a rough broom of it, and sweep the floors and walls of their huts, and find that they are not troubled with fleas for a considerable time afterwards. They have tried brushing dogs with it when their coats are full of vermin, and it appears to answer the same purpose with them. The Indian name of the plant is "Chilpati."—*Kew Bulletin*.

THE MALAYAN COFFEE PLANTERS.—In a recent issue of the *Straits Times*, a correspondent, signing himself "A Planter," protests against a scheme laid before a committee of the United Planters' Association of the Federated Malay States. The scheme suggested that all parchment should be shipped to a curing establishment at Colombo and dealt with there; all the parchment on arrival at Colombo to be sampled and approved; the whole to be pooled or each shipment to be sold separately under estate mark. He urges that the Association should pass a resolution asking the Government of Selangor to give the Association a piece of ground at either Klang or Kuala Klang for the purpose of erecting a curing mill. In a letter to the same paper Mr. E. V. Carey points out that the scheme which the Committee of the U.P.A. is drawing up is only in an embryo state, that the Colombo project was only one of several laid before that body for consideration and that on the agenda for the next meeting of the Association there is a proposal to ask the Government of Selangor to give a piece of land as a site for a curing mill.

ARGENTINE PALM KERNELS.—The palm-kernels to which the following communication relates, were identified at Kew as those of *Acrocomia sclerocarpa*. This is known as the Gru-gru or Macaw palm. It is a native of Jamaica and other West India islands, and of South America from Brazil southwards. The nuts do not hitherto appear to have been turned to any use, though their shell, which is very hard, has been sometimes used for carving.—African Association, Limited, 35a, Castle Street, Liverpool, May 25th, 1897. Dear Sir,—My Board instruct me to ask the favour of some information from your department in regard to a considerable quantity of palm kernels lately arrived at this port from the Argentine Republic. They are informed that a very large tract of country produces the palm from which these kernels are gathered, and seeing the large interest of this Association in palm kernels from the Nigar Coast Protectorate and other West African districts, my Board are naturally desirous to get what information they can in respect to this new competing product. Can you for their information be so kind as to say, is the palm of the Argentine region a true oil-palm, and would the fruit or kernel of this palm be likely to compare closely or differ considerably in oily product, from that in which this Company is interested.—Yours faithfully, (Signed) J. HAMPTON JACKSON, Secretary. The Director, Royal Gardens, Kew.—*Ibid*.

COLOMBO PRICE CURRENT.

(Furnished by the Chamber of Commerce.)

Colombo, Oct. 19th, 1897.

EXCHANGE ON LONDON: CLOSING RATES. Bank Selling Rates:—On demand 1/3 21-32 to 11-16; 4 months' sight 1/3 11-16 to 23-32; 6 months' sight 1/3 23 32 to 1/4.

Bank Buying Rates:—Credits 3 months' sight 1/3 15-16 to 31-32; 6 months' sight 1/4 Docts 3 months sight 1/3 31-32 to 1/4; 6 month sight 1/4 11-32.

COFFEE.—Plantation Estate Parchment on the spot per bushel R14.00 Very scarce; nominal. Estate Crops in Parchment, delivery per bus. no quotations. Plantation Estate Coffee, f.o.b. on the spot per cwt. R81.00 No transactions; nominal.

Liberian parchment on the spot per bus. R5.50. Native Coffee f.o.b per cwt. R61.00.

THE AGRICULTURAL MAGAZINE, COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for November :—

Vol. IX.]

NOVEMBER, 1897.

[No. 5.

SEASON REPORTS FOR SEPTEMBER.

ESTERN Province.—Paddy. Yala harvest nearly over, a good Maha is expected, but prospects would have been better if excessive rains had not spoiled them. Rainfall all over above the average. Fruits and vegetables not as plentiful as usual.

Central Province.—Paddy. Yala harvest over, and sowing, transplanting, weedings, &c., in progress; crop prospects good. Rainfall in Matale 7.40 in. Health of cattle good.

Northern Province.—Paddy. Sowing, and preparation for sowing Kalapokam going on. Rainfall 4.86 in. in Jaffna, 3.25 in. in Mannar.

Southern Province.—Paddy. Yala harvest going on or over. Preparations in progress for Maha. Rainfall 11.37 in. in Galle.

Eastern Province.—Paddy. 6,000 acres in Kalmunai under Pinmari were partially submerged, 2,500 other acres in fine condition. Good crop in Trincomalee district. Rainfall in Batticaloa 7.53 in. and 10.35 in. in Trincomalee. Murrain still prevalent in parts of Batticaloa district.

North-Western Province.—Paddy. Yala crop being reaped, and Maha sowing commenced. Murrain still exists in the province. 12,000 bushels of paddy are expected from the Yala harvest of Pitigal Korale, central division, and 5,182 bushels have been sown for the Maha. Rainfall in Puttalam .91 in.

North-Central Province.—(Not received.)

Province of Uva.—Paddy. Maha harvest over, yield middling. In Wellassa a scarcity of food

is reported owing to failure of last year's chena crops.

Province of Sabaragamuwa.—Paddy. Yala harvest over, good in Kegalle district but damaged by rain in the Ratnapura district. Maha cultivation has also suffered owing to excessive rain. No cattle murrain reported. Rainfall at Ruanwella 14.76 in.

RAMIE FIBRE.

The visit of Mr. J. M. Macdonald, of Messrs. Macdonald, Boyle & Co., London, to Ceylon last month should, if anything will, give an impetus

to Ramie cultivation in the Island. The excitement in connection with this much-discussed fibre—about which, perhaps, more has been written than any other plant, fibrous or otherwise—that was evinced some two years ago, waned as rapidly as it waxed, and the chief reason assigned for this was the technical difficulties that arose in the disposal of the produce. These difficulties, however, Mr. Macdonald brushes aside by his recommendations that the material to be exported should take the form of filasse to be prepared by means of a machine in which he is interested. The degummed and treated fibre, we are informed, will readily command £42 in England, while the cost of producing a ton (at 1½d. per lb.) should not exceed £14, that is to say there should be a profit of some £28 on every ton produced. Taking 1½ tons as what Mr. Macdonald considers a safe estimate per acre, this will represent a profit—when the estate is in full bearing,—that is from the second year—of £42 per acre. Deducting the royalty of 25% on the net working profits due to the patentees, there will be left a clear profit of £32 per acre on the enterprise.

In comparing Mr. Macdonald's estimates with those of other writers, we should bear in mind the method of planting which he recommends, namely, putting the cuttings 1' x 1' apart at first, or 43,560 to the acre, and afterwards taking away every other plant, so reducing the number permanently to 10,190 per acre. In a letter written just before leaving Ceylon, Mr. Macdonald says: "Get 40 tons (that is of stems free from leaves) per acre and Ramie begins to pay, but nothing under 30 tons will pay." Taking £32 as the profit per acre with a field of say 60 tons of sticks, the profit will be proportionately reduced to £21 per acre with a yield of 40 tons, and to £16 with a yield of 30 tons. But Mr. Macdonald bases his original cultivation on large acreages; with smaller plantations the cost of producing a lb. of prepared fibre may be expected to be greater, so making the profits smaller; and Mr. Macdonald gives R25 as a fair average profit per acre. Hitherto it has been customary to grow ramie 4 or 5 feet apart. Now, if we compare the number of plants in an acre put 2' x 2' apart and the number per acre put 4' x 4' we find that there are nearly 8,000 plants more per acre in the former case, so that the method of planting advocated by Mr. Macdonald upsets all previous calculations as to the amount of produce per acre and makes his own estimates unique. It may be said that there is a certain limit to the productive power of an acre of land, and that the amount of produce varies within certain limits which Mr. Macdonald's estimates overstep on the higher side. It may further be said that it is a bad system of agriculture which recommends close planting with the object of getting more produce. This latter statement applies of course with great force to fruit-bearing crops as we know so well in the case of the coconut palm. But the ramie is a stem-bearing crop, and we also know that when trees are planted close they tend to grow spindly, and in the case of a branching tree that the tendency to

branching is in a degree suppressed, whereas with plenty of light and air surrounding it the tree will grow more symmetrically, developing proportionately in a lateral direction as it grows in height. But in the ramie shrub the tendency to send up straight and tall stems without any lateral branches is a decided advantage, for the longer and straighter the stems and the fewer the side shoots the better the fibre. Indeed, in the cultivation of the plant it is necessary to remove all lateral foliage buds in order to preserve the continuity of the fibre in the stems. So that by growing the plants close together, beside the advantages of the weeds being kept down and the ground shaded—for ramie does not stand drought well—we as it were force the plant to produce long straight stems of the most acceptable form. This close planting of ramie has certainly thrown a new light on the method of cultivation which, as we have shown, most materially affects the quality and quantity of the fibre and also nullifies all previous calculations as to yield and profit.

As regards the cutting of sticks, Mr. Macdonald advises that this should go on almost continually, so that the sticks fit for cutting will be gathered at the proper time. Periodical cuttings he deprecates on the same grounds that periodical pickings of tea leaf are to be deprecated. There is no doubt that continual cuttings of ramie would result in the production of a more uniform quality of fibre. Mr. Macdonald estimates that one man can go over two acres in a day cutting the mature stems.

The chief point it seems to us in embarking on a new planting industry such as this is to discover the most suitable localities for cultivation. Ramie wants a loam or clay loam (not too heavy) and the more atmospheric moisture the better. Dry sandy soils are objectionable, but on the other hand land inclined to be water-logged is to be avoided.

The plan adopted by the patentees of recovering the royalty on their machines is certainly novel and speaks well for their certain faith in the prospects of ramie cultivation; for when they demand a percentage on the net profits of cultivation they at once identify themselves with the success or failure of the industry. If ramie cultivation succeeds, the patentees secure their royalty; if it fails they lose it. That is certainly a very fair bargain.

On the whole we confess to be favourably impressed with the prospects of ramie, and we feel justified in advising local growers—particularly those already engaged in cultivation and with spare land available—to give it a fair trial on a moderate scale, and according to the methods of culture advocated by Mr. Macdonald. If there is no central degumming factory now, we fancy it must come before very long, and those who have their reserves of ramie will then be able to launch into extensive cultivation after, of course, having satisfied themselves by a tentative measure that they were justified in so doing. With them it will be "first come first served" by the factory, and to the £42 per ton which is so temptingly offered.

OCCASIONAL NOTES.

The visit of Mr. Macdonald of Ramie fame has aroused a new interest in the cultivation of this well-known fibre plant, and we are inclined to think has also engendered a certain amount of confidence in the new industry. There was some talk about our having got the wrong variety of the plant. We will not here enter upon the discussion of the botanical difference between Rhea and Ramie, suffice it to say that Mr. Macdonald has stated that we have got the correct sort which could be easily identified by the white-back leaves that characterize the true Ramie. We should therefore abandon the word "rhea" for "ramie," as in this instance there is a good deal in a name.

We may state for the information of our readers that Ramie fibre cuttings can be had either at the School of Agriculture or from Messrs. Clarke, Young & Co., at Rs. 20 per 1,000 cuttings one foot long. We shall be glad to show the specimens of fibre, thread, and cloth prepared from ramie—which were given to us by Mr. Macdonald—to anyone who may desire to inspect them.

Arrangements which had been made for a first excursion-class of agricultural students, when the Henaratgoda Gardens were to be visited, had to be abandoned owing to the irregularity of the train service as a result of the big rock slip on the line.

We have to thank Messrs. Freudenberg & Co. for samples of the following manures:—Blood-meal, Kainit, Basic Slag and Sulphate of Potash, as well as for a number of pamphlets treating of the properties and uses of these fertilizers. We hope to make reference to the manures in their relation to Ceylon crops, in a future issue. In the meantime we would only say that the fact of Messrs. Freudenberg & Co. having brought these fertilizers into the local market must prove a great convenience to growers—at least to those who are wise enough to think of reducing their manure bill by replacing their stock compounds with the equivalent of more cheaply mixed fertilizing agents.

We are glad to have among our numerous exchange that most acceptable and up-to-date journal, *The Australian Tropical Agriculturist*, for which we thank the Editor. We are greatly obliged to Messrs. Hynde & Stark of Zomba B.C. Africa for their letter of the 26th August, and are pleased to know that our magazine reaches them. P. G. S.'s letter from Mildura, Victoria, received.

INSTRUCTION IN AGRICULTURE.

In his Administration Report for last year, Mr. W. E. Davidson, Assistant Government Agent of the Province of Sabaragamuwa expresses his views on Agricultural Education—with reference specially to the case of the native cultivator—

and indicates the directions in which he thinks the School of Agriculture should work:—

"What we ask from the Agricultural School and the Royal Botanical Gardens is (1) that the Superintendent and Director should guide us when we want information; (2) that we should be supplied with seeds and young plants when we want them; and (3) that the Superintendent of the Agricultural School, or a really competent assistant from the school or from Henaratgoda or Peradeniya, should deliver special popular lectures on any new garden development. *E.g.*, this year we want in Four Korales to have all the information we can get on (1) the growing and preparing of rhea fibre; (2) the preparation of the tanning material in the green arecanut, and an analysis of the increased profit to be derived from preparing the product locally. Again, this year and next in Three Korales I want the whole country to hear all the facts and figures about plantain culture, so as to have their produce properly cultivated and ready for the railway to carry it to the market. If Mr. Drieberg can prepare popular lectures on these points with lemelight illustrations and such-like attractions, I will guarantee to find twenty audiences in selected neighbourhoods, and the net advantage to the country will in one season exceed all the advantages derived from any attempt at local school training. In fine, from my point of view, the one benefit derivable by this district from the appointment of an Agricultural School in Colombo is that the Superintendent, or a competent assistant, should deliver locally popular lectures on popular subjects. He should fulfil the same functions as are discharged by a "County Council" lecturer, *e.g.*, as in Sussex.

"The subject is fully discussed in my reports of the 2nd December, 1895, and of the 16th February, 1897.

"In the same reports I have reviewed the history of the attempts to introduce new paddy, *e.g.*, muttasamba, pulukhamban, and Carolina, and of barley; of new garden fruits such as pomegranate, mandarin orange, Madagascar papaya, pomeloe, loquat, jamba, guava, and the Cochui goraka; and of new commercial products, such as tea, Liberian coffee, cacao, cotton, cloves, pepper, and rhea fibre. The growing of rhea fibre promises to develop into a cottage industry."

We have not had the pleasure of reading the two reports referred to by Mr. Davidson in which he has fully discussed the subject of Agricultural Instruction, for though, curiously enough, we receive the Agricultural reports and papers published in India and most of the British Colonies, we are not supplied with the local publications bearing directly on the agriculture of the Island.

Nearly all the suggestions made by Mr. Davidson were embodied in the scheme which was drawn up by the Superintendent of the School of Agriculture for the re-organising and better equipping of the school and for carrying on the work of the Agricultural Branch of the Educational Department on more practical lines. This scheme was appended to his annual report for 1896, and reprinted in the September number of

the Agricultural Magazine. The additional suggestion that the lectures in the provinces should be illustrated with limelight views and other attractions is a very practical idea. When it is remembered that a sum of nearly R9,000 is being saved by the withdrawal of Agricultural Instructors and other measures of retrenchment, it might reasonably have been expected that some alternative and more practical programme of work for the improvement and extension of native agriculture would be adopted, but so far no action has been taken in this direction. The views of so experienced an official as Mr. Davidson, who has been giving more than the ordinary attention of a revenue officer to native agriculture, coming also when the scope of working the Agricultural School has been diminished, ought we fancy to prove acceptable to Government and help towards the drafting of a scheme which would make the most of the material available in the school. We would advise further that in connection with the proposed lectures, there should also be demonstrations as far as possible, at the time of and in illustration of the lectures, and later also in a more practical way out of doors, and even literally in the field. Such practical demonstrations are always given in connection, for instance, with the itinerating dairy classes in England. There is nothing like going to the very doors of native cultivators to reach them. What we want is an agricultural campaign, so to speak, in the villages.

In his last Administration Report the Director of Public Instruction refers to the good work being done by Mr. Lewis, the Sub-Inspector of Schools in the Central Province. Mr. Lewis may be called an old boy of the School of Agriculture, where he acted for a long period as a master. We have a vivid recollection of his enthusiasm in all that pertains to the betterment of native agriculture, and can well imagine his making the most of his opportunities as an Inspector of Schools—who is *par excellence* a provincial grandee—to preach on the means available to the native cultivator for improving his status and prospects, and not merely to preach but to see that his precepts are put into actual practice by, for instance, growing such new products; the seeds and plants of which Mr. Lewis himself would supply them with.

Now we are inclined to think that Mr. Lewis' self-imposed duties provide an admirable example for imitation, for if his work is fruitful and commendable, why should not the School of Agriculture adopt the same course and work on the same lines as he pursues,—only on a wider scale. An Inspector of Schools is a busy man with little time to deviate from the road that leads from one school to another, and his agricultural skirmishes must necessarily be confined to his line of route and to school centres: but we take it that schools are not so numerous in this country, nor are they always the most convenient coigns of vantage from which to attack the agricultural labourer. The neighbourhood of schools may, we confess, be assumed to be the most enlightened centres of rural life, and therefore the people in such localities may be supposed

to be capable of readily assimilating the teachings of enlightened agriculture. But we would proceed further and work deeper, and, as we said, go to the very doors and fields of the agricultural labourer in making not mere skirmishes, but in carrying on a well-planned campaign, in which the impedimenta would be represented by seeds and plants, models and maps, machines, diagrams, *et hoc genus omne* so far as relates to agriculture.

In India—in connection with the Saidipet College, for instance—we know that a special feature of the practical work is the going among the cultivators, studying their needs and ministering to the wants, whether they lack information and instruction or such material requirements as seeds and plants. Dr. Morris, in a late address on Tropical Agriculture in Jamaica, is reported to have declared that there is nothing which "promises to be more widely appreciated by the mass of cultivators or calculated to be of more permanent benefit than the plan of sending agricultural instructors to advise and encourage them."

We think we have written enough to show that before any good may result from the teaching of the School of Agriculture its work must be made of a more practical character. Some will say that lecturing the people is not a very practical way of teaching them, but by lecturing we do not mean the declamation of the classroom lecturer, but a method of speaking to the people not merely in words, but by illustration and practical demonstration and all the available means of effectually appealing to all the five senses of an individual. Personal contact with the masses is what is necessary in order to influence them, no matter in what direction, and until some such programme of work as has been recommended by Mr. Davidson and which is supported (as we have shown) by so many independent authorities, is adopted, the question will continue to be asked, as it has been so often asked during the past year:—"What good has come out of the Agricultural School?"

FRUIT CULTURE.

(Continued.)

But after all the French pebble drain which we have described, however great an improvement it may be on open channels or no drainage at all, is far from being perfect, inasmuch as it is comparatively a make-shift affair, which requires periodical cleaning out. The most perfect and satisfactory though costly system is undoubtedly the laying down of permanent drain tiles. These, when properly laid, outlast several generations and carry off the water with three or four times the certainty and swiftness of the French drain, while they never clog. Instances are numerous where by this means large areas of worthless "drowned" land, in which cattle could not venture without risk, has been converted into productive market farms.

The gospel of trenching and draining is a hard one; it means considerable outlay long before a return can be expected. To minimise this and attain a certain sort of success, though

not the best, the total expenditure might be spread over a number of years.

Thus an orchard of say 20 acres upon a gentle slope may be trenched up in strips of land straight down the incline with a drain alongside each strip. For example, let the first strip laid out be 20 ft. wide and the drain to follow. The next plot of 20 ft. is ploughed up in the first year and used for a catch crop. In the second year it is trenched up exactly as was No. 1. Next to this comes the 3rd plot trenched up at the same time as No. 1. Then comes a second line of drain followed by plot No. 4 treated as was No. 2 for a first year's catch crop and a second year's trenching. And thus the alteration goes on over the whole area. By this means about half the cost of completely trenching an acre to be devoted to fruit culture would be distributed over perhaps two or three years.

The time of trenching is the best time for manuring if the natural poorness of the soil requires that assistance. The old method of putting a bushel of manure near the foot of the tree will not do at all. The manure must be scattered with the aid of a six-pronged fork so as to diffuse it pretty evenly throughout the whole mass of trenched-up soil. If your supply runs short reserve it for the upper two feet of soil instead of working it deeper, and if you have a still shorter supply you will have to be very sparing. You will find it more thrifty to leave the top surface of your land rough. Then scatter what manure you have over the rough surface and turn it in when you finally level it down to a cultivable smoothness. Practically this amounts to a top-dressing only. When working with a clayey soil, manure that is not particularly rich in animal matter, but contains much of incompletely decomposed straw find its best use in aëration and preventing the packing together of the soil. We are apt to look upon manuring as a sort of cure all, which with the help of a copious water supply is to save the labour of trenching up the soil, pruning the trees to a fruitful condition, and looking well after them generally. Have we not given them plenty of compost? Then why don't they bear satisfactorily? The fact is the majority of fairly fertile soils that have been industriously cultivated will suit fruit trees without other manure than a light top-dressing, for years, if only they get the inevitable and necessary opening up by trenching. Heavy manuring is the cultural need of annual crops, which have to spring up, blossom and seed at racing speed, to get through with their short lives within the year. Your fruit trees do not take life so fast, and they therefore don't require the stimulus appropriate to cereals where work is done in 5 or 6 months.

(To be continued.)

THE MANIOC PLANT.

Dr. R. H. Grenning, who in 1874 addressed the Secretary of State for India on the subject of inducing the people of India to freely cultivate Manioc, especially among their hedgerows, so that the trees may serve as an alternative foodstuff in

seasons of scarcity and famine, has again taken up the question in connection with the present famine in India. Dr. Grenning, who writing last year, describes himself as "blind and in indifferent health and in my 79th year" believes that manioc tubers will prove a valuable stand-by when other crops are killed by drought, and refers to them as "a God-ordained food for drought and famine" which will be the means of saving millions of pounds and millions of lives. Livingstone calls it the staff of life in Africa, while in Brazil, Chili, Peru and Central America it is a universal food, and it is a curious fact, says Dr. Grenning, that in these countries we never hear of famines though there are often very long droughts.

Two species of manioc are recognised, one with a sweet root (*M. Aipi*) and the other (*M. utilissima*) bitter and poisonous from containing prussic acid in its juice. The poisonous properties of the latter are, however, easily got rid of by squeezing out the juice or by heating. The poisonous kind differs from the other by having its leaves and the summits of the branches darker, and the roots have a purple hue beneath the cuticle which is wanting in the sweet kind. But the easiest test is to taste the broken roots; one is sweet like almonds, the other bitter and repulsive. The Brazilian arrowroot of commerce is nothing else than the starch (known as "polvilho") from manioc. Dr. Grenning believes that manioc, which has practically the same composition as rice will exactly replace it in the economy of the native Indian during times of scarcity. He writes thus enthusiastically in a letter to Lord Lorne:—"Men like Stanley, Selous, Bishop Tucker and others who know much of Africa, could assist and bear testimony to the thesis that manioc is God's natural provision against drought and famine, and is the secret means of saving people when drought destroys rice and other kinds of food."

The Superintendent of Botanic Gardens, N. W. P., India, reporting on Dr. Grenning's scheme says that manioc is extensively cultivated in Bengal, and is also well-known in the Madras and Bombay Presidencies. It is not raised as a commercial crop as it cannot compete with the potato and sweet potato and so does not pay. The Superintendent of Botanic Gardens, Calcutta, does not believe in the drought-withstanding properties of manioc, and states that it would fail as a food crop in seasons when rice also fails for lack of moisture.

Another authority on the subject is Mr. Robert Thompson, who writing from Lan Cayetano, Columbia, mentions that some 20 varieties are known in cultivation there, and that the plant could be grown from sea-level to full 6,000 feet. He then goes on to say that its peculiar and most commendable merit consists in its capacity to flourish in regions not only where prolonged droughts are experienced, but also in comparatively desert regions. Under favourable conditions as much as 25 lb. is procurable from one plant, but allowing an average of five pounds per plant, ten tons per acre would result if they are planted a yard apart.

It has been said that in most parts of India the manioc is not in favour with the people.

But the plea for manioc-growing is not as a principal crop, but as a stand-by in times of drought, during which periods the question of satisfying the palate must be secondary to the cravings of the stomach; besides, it is well-known that in seasons of scarcity the poorer classes have to resort to all forms of vegetable products, with which at ordinary times they would spurn to appease their hunger.

The State of Travancore would seem to be the only place in India where manioc is cultivated at all systematically, and "Tapioca Cultivation in Travancore" is the subject of an interesting paper by Mr. A. M. Sawyer which appeared in *The Indian Forester*, Vol. xxi, pages 290—296. We have, however, written more than we intended for the present issue on the subject of manioc, and must reserve any reference to a epitome of Mr. Sawyer's paper for another issue, when we shall also deal with the cultivation of manioc in the Island.

ARECANUT PREPARATIONS.

Dr. Watt gives the following methods of treating Arecanuts for the market in India:—In some cases after the nuts are husked they are boiled till soft; the slices are rubbed with the inspissated water in which the nuts are boiled, which become impregnated with the astringent principle contained in the nuts; the slices are then dried in the sun, and in this condition sent to market. Again, instead of being sliced and boiled the nuts are sold entire. In other places (Manipur) they are sold in the streets with the husk neatly opened up like a fringe to show that the nuts are fresh. In the Bombay and Mysore *Gazetteers* interesting details are given regarding the methods of preparing the nuts for the market. In Thana the growers sell the nuts wholesale to a tribe called Vānis, who by different treatment, prepare six classes of nuts. To prepare *phulbari supāri* or those with flower-like fissures, the nuts are gathered when yellow but not quite ripe. The husk is stripped off and the kernels are boiled in milk or water in an earthen or tinned copper vessel. When the nuts grow red and the water or milk thickens like starch, the boiled nuts are removed and dried in the sun for seven or eight days. The red *tambdi* arecanuts are prepared by boiling ripe fruits stripped of husk in milk or water with a small quantity of pounded Kath (Catechu), lime and betel leaves. As soon as the boiling is over, the nuts and boiling milk or water are removed in a basket with a copper vessel under it to catch the droppings. To make *Chikni* or tough betel-nut, the nuts are gathered when they are beginning to ripen, and when the boiling is over the catechu-like substance left on boiling is rubbed over the nuts, when they are dried in the sun. This process is repeated until the nuts grow dark red. To make *Lavangachuri* or clove-like nuts, the kernels of tender fruits are cut into clove-like bits, and after boiling in water are dried in the sun. *Pandhri* or white nut is prepared by boiling the ripe fruits with the husk and afterwards drying in the sun till the husk is easily removed. To prepare *dagdi* or strong nut the fruit is gathered when ripened

into hardness, and after stripping it of the husk, it is boiled and dried in the sun. To make *Kāphadi* or cut nut, the kernels are cut out of the nut when tender and dried in the sun without being boiled or soaked in water. In Mysore after removing the husk the nuts are boiled in water, then cut into pieces and dried in the sun; or they are first cut into pieces, then boiled in water with catechu and leaves of the betel vine and afterwards dried in the sun, when they are fit for sale.

Extract.—The water in which arecanuts are boiled becomes discoloured and thick; this on being inspissated forms *Kossa* or the catechu of the greatest astringency; but the best catechu of a red colour is obtained by boiling in fresh water the nuts which have been previously boiled.

The ripe fruit is boiled for some time in an earthen or tinned copper vessel and the nuts together with the boiling water are poured over a basket. The boiled water is caught in a tinned copper vessel and is allowed to thicken of itself or thickened by boiling into a black very astringent catechu. Sometimes these nuts are boiled a second time in fresh water, when the boiled water gives a yellowish brown catechu. The refuse after boiling is sticky and is used for varnishing wood and for healing wounds.

Chemists, after examining into the chemical character of the seed, have come to the conclusion that *catechin* is not a constituent of arecanuts, and that any extract made from them must be essentially different to the catechu of the acacia, and is rather to be considered a kind of tannic matter of the nature of *Ratanhia-red* or *Cinchona-red*. It is interesting to learn further that incineration of the seed produced 2.26 per cent of ash, which, besides peroxide of iron contained phosphate of magnesia.

BISULPHIDE OF CARBON FOR PRESERVING STORED GRAIN.

We have lately been consulted as to the best means of preserving paddy from the attack of weevils, and among other remedies recommended bisulphide of carbon. This is the chemical which is now most commonly used against *Calandra granaria* and *Calandra oryzae*.

We find in that useful publication, *The Agricultural Journal* of the Cape, full and clear instructions given by the Government Entomologist as to the method of using bisulphide of carbon, and we reprint them for the benefit of our readers.

Bisulphide is commonly considered to be a dangerous explosive, but there is no danger to be apprehended from its use if it be kept out of the reach of fire.

Carbon bisulphide has for a number of years been acknowledged as the simplest, most effective and least expensive of the many agencies recommended and used for the destruction of weevils and other grain-infesting insects. As supplied by chemists, it is a colourless liquid which, owing to impurities almost invariably present to some extent, possesses a penetrating and exceedingly vile odour not unlike the stench from a decomposed egg. The liquid rapidly changes to a heavy vapour when exposed to the air at ordinary temperatures, and to this property is largely due its utility as an insecticide.

The vapour is very inflammable and highly poisonous to animal life.

To ensure success the grain to be treated should be in a bin with tight sides and bottom, but the treatment of grain even in open cribs is reported to be successful by the Mississippi Agricultural Experiment Station, where experiments in the use of this insecticide were conducted for many years.

The chemical is placed in shallow dishes or on pieces of cotton waste or other absorbent material on the surface of the grain, or is even sprinkled directly on the surface of the grain. If there is a depth of more than five feet of grain in the bin, it is well to put part of the charge well into the mass either by pouring it in through a tube or by burying material soaked in it. After distributing the charge, the bin is usually covered with blankets or other heavy cloths to shut off the air; the fumes, however, being so much heavier than air, cannot escape upwards to any great extent. The liquid soon evaporates, and the fumes, descending, penetrate to all portions of the mass of grain, carrying death to all insect and other animal life.

If the bin is tight, the charge need not be over one pound of the bisulphide to each forty bushels of grain; one pound to each hundred bushels is said to be used with success at the experiment station alluded to above. It is customary to leave the grain exposed to the fumes for at least twenty-four hours. A longer exposure does not injure the grain for milling purposes, but an exposure of more than two days affect its germinating powers. After opening the bin, the fumes gradually pass off, although if the bin is very tight it may be necessary to stir the grain or even throw it out of the bin.

If the grain is in open bins and much affected by weevils, it may be desirable to repeat the treatment in six or eight weeks, particularly if the conditions of temperature are favourable for the rapid propagation of the insects; under favourable conditions of heat the common grain weevil (*Calandra granaria*, Linn.) passes through a generation during this period. It is also sometimes desirable to have the room in which the grain is stored or even the whole building fumigated, in which case the space should be made as tight as possible and not less than one pound of bisulphide evaporated for each one thousand cubic feet. Many mill owners in America periodically fumigate their entire buildings. The bisulphide is distributed about in shallow vessels or on absorbent material as is done when grain in the bin is treated. Because of the disagreeable and poisonous nature of the fumes and their tendency to sink to the lowest level, it is customary, when there is more than one floor, to begin the distribution on the ground-floor and to work upwards, making the exit from the top floor.

While carbon bisulphide is poisonous to all kinds of animal life if inhaled in quantities, the amount breathed by a man in handling and distributing it is insufficient to do him any harm. The only real danger from the substance is its *inflammability*, and care must be taken to prevent anyone approaching where it is being used with a flame of any sort; even a lighted pipe or cigar is dangerous. If this precaution is observed, there is no cause for anxiety.

Cape Town chemists sell carbon bisulphide at 2s. per pound in small quantities and generally at a slight reduction from this price when ten pounds or more are taken. The demand for it is small and no dealer carries very much in stock. It is not unlikely that if one is likely to require much, it would pay to import a quantity direct from England or the United States on his own account. Edward R. Taylor, Manufacturing Chemist, Cleveland, Ohio, U.S.A., makes a specialty of carbon bisulphide for fumigation purposes, and for several years has been supplying a very satisfactory grade which he calls "Fuma Bisulfide"; this he sells at 10 cents (about 5d.) per pound in fifty pound drums. From New York, the carriage on goods to South African ports is said to be even less than from London, so it might prove a good investment to some grain dealers to make a trial of importing a few fifty pound drums from him.

THE VITALITY AND DISSEMINATION OF SEEDS.

(Continued.)

As to how long seeds carefully preserved retain their vitality, and the power of germination remains, there is little precise and reliable information, though attempts have often been made to solve the question. The labours of Dauberry, Henslow and Lindley afford much material for reflection, having been conducted in a methodical and painstaking way, whilst their labours extended over a long series of years.

More is known of the seeds of cultivated species, for, being articles of trade, merchants make a careful study of a matter so closely affecting their interests. Coffee seeds, in order to grow, require to be sown immediately after ripening. On the other hand, melon seeds have been said to retain their vitality for upwards of 40 years. (Balfour, *Manual of Botany*.) The last example could only apply if the seed was preserved under special conditions, not exposed to the air. It is acknowledged that seeds of the Brassica family, (to which belong mustard, cabbage &c.) will germinate when 10 years of age, though a less percentage of growths arrive after the 6th year. Many gardeners maintain that the progress of certain vegetables is more regular, more gradual, with less chance of running away to bloom prematurely, when the seed is 2 years of age than when it is threshed from the pod. On the contrary, should conditions adverse to germination prevail, such as drought, or should mischievous insects abound, then new seed has a decided advantage as possessing more moisture and strength. The story of wheat produced from the Egyptian pyramids, and which was supposed to have been placed there at the time of the burial of the mummy, tests the credulity of the scientist as well as that of the husbandman. De Candolle in his *Origin of Cultivated Plants*, confesses that he does not believe in the so-called mummy wheat, which the Count of Stenburg is credited with growing at Prague, and which is supposed to have produced a new race of wheat. He states that the Arabs slip modern seeds into the tombs (even maize, an American plant) for the purpose of imposing upon visitors!

Mr. William Carruthers mentions an authentic case of the seeds of the sacred Lotus (*Nelumbium speciosum*) which were known to have been more than a hundred years in the British Museum, being grown by Robert Brown. Difference in germinating, says Carruthers, are mainly due to difference in the structure of the testa or outer covering of the seed. Where the testa, as in most cereals, is thin and soft, the dessication of the seed is rapid, but where hard and compact, the seed is protected from the air and the embryo is preserved in a living condition for a longer period. Thus the seeds of *Canna indica* and *Asparagus plumosus* have a very tough covering, and the only way to release the embryo is to boil or nearly boil them for 3 or 4 hours.

Some writers on horticulture as well as botanists have drawn up tables to guide gardeners as to the age at which seeds will germinate. These are interesting as giving different opinions, but as not being of any great practical value we do not reproduce the lists of Beecher, Watkins, and M. de Vilmorin. The last writer, referring to germination, says that the duration of the germinating faculty depends greatly on the condition more or less favourable under which the seeds have been harvested or preserved. Nothing contributes more to destroy seed than the influence of humidity and heat; these are difficulties which are encountered when seed has to be sent to tropical regions. There is no better means of preserving seeds than to put them into linen bags in a dry airy place.

When attention is called to the vitality of the seed of those indigenous plants called weeds, our experience is more at fault, and serious difficulties arise. How long will seed survive which have been buried deep below the surface where light and air cannot penetrate? It is a common experience to find the seeds of weeds lying dormant until again exposed to the elements, or brought within a reasonable distance of the top, and noxious annuals and biennials frequently reappear where such plants have been allowed to mature and ripen their seed, leaving a legacy for many successive seasons. It is obvious that no obnoxious plant should be allowed to reach maturity, as a few specimens are sufficient to poison a field.

Rhind in his *Vegetable Kingdom*, referring to the fecundity of plants, writes as follows:—"The fecundity of plants, in other words, the astonishing number of germs or seeds which they produce, is one of the causes which are most powerful in facilitating their reproduction, and in affecting their surprising multiplication. A single capsule of the white poppy has been known to contain 8,000 seeds, and a capsule of the *Vanilla* from 1,000 to 1,500; a single stalk of *Zea Mays*, Indian corn or maize, will produce 2,000 seeds; a single plant of tobacco has been found, by calculation, to possess the almost incredible number of 360,000, and a single stalk of spleenwort has been thought, by estimation, to produce at least a million seeds."

Why does the seed lie idle so long in the ground, and in a dormant or lifeless condition? Without sufficient moisture to saturate and soften the

seed germination does not commence. As long as the seed is excluded from oxygen no movement need be expected, even if other conditions are favourable. In the case of seed under deep water this has been often exemplified. Again, a moderate temperature must exist, or seeds will not sprout. Some grain will start at a much lower temperature than others, but this does not generally apply, and different species need different degrees of heat according to the nature and temperament of the plant. The common and coarser indigenous plant will of course always have the advantage over the tender and cultivated one

VETERINARY WORK IN CEYLON.

1.—*The Prevention and Suppression of Contagious Disease.*

During 1896 the Island has been comparatively free from disease.

Western Province.—During the first half of the year cattle plague and foot-and-mouth disease existed in and around Hanwella. It was suppressed and the Province was free for the remainder of the year.

Cattle Return for the Western Province, 1896.

Number of cattle:—

Buffaloes	31,904
Black cattle and other breeds			127,863

Number affected by disease:—

Buffaloes	4,683
Black cattle and other breeds			13,026

Supposed nature of disease: Principally foot-and-mouth disease.

Recoveries	14,937
Deaths	1,780

Central Province.—There were outbreaks of murrain in three villages of Yatinuwara and two villages of Tumpane, in Kandy District, during July and August. The villages were proclaimed infected areas. The proclamation regarding Yatinuwara was revoked in December, the disease having disappeared; that regarding Tumpane was still in force at the end of the year.

There was an outbreak of hoof disease in Udalapata in August, and certain villages were proclaimed infected areas. Cases of hoof disease were reported from Pahala Hewaheta, Pata Dumbara, Harispattu, Yatinuwara, and Tumpane, and of sore mouth from Pata Dumbara and Harispattu. The outbreak was not severe, and it was not considered necessary to take steps under the Ordinance.

MATALE.—Cattle murrain was prevalent in Warakamura and Purijjala in Matale South during the months of June to August, 1896. Three buffaloes and seven head of black cattle in Warakamura and four head of black cattle in Purijjala were attacked with the disease. Of these, one buffalo in Warakamura and one head of black cattle in Purijjala recovered, and the rest died. The disease was reported to have been introduced into Warakamura by some cattle brought for sale from Kunchuttu Korale of the North-Central Province. Prompt measures were taken and the spread of the disease was checked. Only one other case of murrain was reported from Aluwihara, about two miles from the town. Foot-and-mouth disease prevailed in almost all parts of the district, but no animals died from it.

NUWARA ELIYA.—There was no murrain during the year. There was foot-and-mouth disease in

almost every village of the district. Only a few cases proved fatal.

Cattle Return for the Central Province, 1896.

Number of cattle :—		
Buffaloes	...	42,387
Black cattle and other breeds	...	43,064
Number affected by disease :—

Supposed nature of disease: Foot and-mouth disease and murrain.		
Recoveries	...	7,669
Deaths	...	1,459

Northern Province.—MANNAR: In January and February a purging sickness prevailed amongst black cattle and buffaloes in the Iluppapadavaipattu, and 27 cattle died out of 52 attacked, the rest recovering. The disease is believed to have been introduced from the adjacent Vanni villages where murrain was prevailing.

About the same time some cases of foot-and-mouth disease occurred at Kannarponnai, but no mortality was reported. The cattle were quite healthy during the rest of the year owing to the good supply of water and pasture.

Cattle Return for the Northern Province for 1896.

District.	Number of Cattle.		Number affected by Disease.		Nature of Disease.	Recoveries.	Deaths.
	Buffaloes	Black Cattle or other Breeds.	Buffaloes	Black cattle or other breeds.

	193,893						

Southern Province.—Foot-and-mouth disease prevailed to some extent in July in the Four Gravets and Wellaboda Pattu, in September in the Four Gravets and Talpe Pattu, and in October in Bentotawallawiti Korale. There was no serious loss.

Eastern Province.—There were no cases of cattle murrain in this Province during 1896. Hoof-and-mouth disease prevailed all over the Batticaloa District and in the town of Trincomales and Kaddukulam Pattu, though not of a virulent type, and there were no cases of death from the disease.

North Western-Province.

Place.	Number of Animals infected with Foot-and-Murrain.	Number of Animals infected with Foot-and-mouth disease.
Hiriyala hatpattu	...	Nil
Weudawili hatpattu	...	Nil
Wanni hatpattu	...	Nil
Dewamedi hatpattu	...	37
Katugampola hatpattu	...	629
Dambadeni hatpattu	...	339

CHILAW DISTRICT.—Cases of murrain were reported in July as having occurred in Pulichchakulam, but the animals were isolated and the disease did not spread. Cases of murrain were also reported from Millawa, Potuwatawana, and Kahatawala in the southern division. The disease was supposed to have been introduced by animals purchased from the North-Central Province. 19 head of cattle were

attacked, but 3 only died, and the disease did not spread further. No cases of murrain were reported from the central division.

Cases of foot-and-mouth disease occurred in all three divisions, but no deaths seem to have followed.

PUTTALAM DISTRICT.—There has been little hoof-and-mouth disease within this district. The only imported outbreak was in Chenakudiyiruppu within the gravets of Puttalam in July, when 34 cases were reported. None of the animals attacked died. The village in question has an imported cattle trade, most of the animals being brought from the north. As regards murrain, Akkarai Pattu south, which connects Kalpitiya peninsula with the mainland, has been the worst sufferer. There was a sharp outbreak lasting through October and November, during which period 99 animals were reported attacked, chiefly at the important village of Kattakadu. In Demala Hatpattu, Peravili, and Pandita Pattus, which adjoin the Puttalam-Kurunegala road, have suffered rather badly. The disease is supposed to have been introduced into Pandita Pattu from Wilachchiya Korale in Anuradhapura. Puttalam Pattu itself has been singularly free, as only seven cases were reported.

Of the animals attacked, about 100 were buffaloes, the rest black cattle. The annexed statement shows the loss in each division:—

Pattu.	Affected.	Died.
Puttalam (January)	... 7	3
Pandita (January to April)	... 29	3
Peravili (August to November)	... 57	29
Akkarai south (October to November)	99	47
Total	... 192	82

North-Central Province.—Murrain has been prevalent in this Province throughout the year: during the first four months it existed in the Nuwaragampalata and Tamankaduwa district to a great extent. About the end of April Tamankaduwa was freed from it, and nothing but a few cases of foot-and-mouth disease during the second half-year troubled that district again. In Nuwaragampalata the disease continued throughout the year, although not with the severity of the first half-year. In Hurulupalata and Kalagampalata the disease has broken out at places now and again, but not to the extent of the other two divisions. Hoof-and-mouth disease has prevailed only in Nuwaragampalata and the Meda Pattu of Tamankaduwa, but it has not been much noticed.

The information detailed above was received from the Government Agent of each Province. During the latter part of the year I requested returns to be furnished to me in the form in which the return from the Northern Province is rendered. It was found not possible to give exact details for 1896, but the most reliable information has been given, and complete returns in the form indicated will be compiled for 1897 and be rendered half-yearly. Foot-and-mouth disease appears to have given considerable trouble. Fortunately there has been no serious loss. It may be classed as a mild disease, and large numbers of deaths should not occur if the animals are carefully attended. The treatment for this disease has been several times published in official reports and in the public press.

For several years past Prof. Hummel of Leeds has been working on the dyes and tans of India, and recently, in conjunction with Mr. A. G. Perkin, who has submitted each dye to a critical chemical analysis, a most valuable series of papers has been published on Indian dyeing materials. Sir F. Abel, Director of the Imperial Institute, writing to Dr. Watt with reference to the labours of Prof. Hummel, says "he sends me a list of eight (dyestuffs) which are sufficiently rich in colouring matter to render them worthy of examination both chemically and tinctorially in preference to others." The following is the list in which the dyes are arranged in the order of their tinctorial value:—Myrica Nagi (bark), Delphinium Zalil (flowers), Carpesium abrotanoides (whole plant), Nyctanthes Arbor-tristis (flower tubes), Kandelia Rheedii (wood), Gossypium herbaceum (flowers), Thespesia populnea (flowers), and Mangifera indica (bark). It will be seen from this list of Indian dyes that all but the first three are familiar trees in Ceylon.

Mr. G. E. Dugmore, writing to the Grahamstown Journal, urges upon cattle-owners the importance of inoculating their herds against rinderpest. He says: "I can give names if necessary; one man out of 70 has not one left, another out of over 200 has 19 left, another out of 50 has 3 left, another out of 40 has one left, and another out of 146 has 26 left. Where inoculation has been carefully done while the herd was healthy the results have been as follows:—Out of 278, 4 dead; out of 160, no loss; out of 490, 5 dead; out of 200, 5 dead. These I have had from thoroughly reliable men. They have all been inoculated twice, and are now doing it a third time, and I could multiply instances indefinitely. How long the immunity will last we do not know, but the following is thoroughly established: Get the disease and without inoculation, losses are 99 per cent; get the disease and then inoculate, losses 50 to 80 per cent; inoculate with good bile before herd is affected, and losses will be nil to 5 per cent.

The following is given as the approximate average analysis of the fresh orange as calculated by Prof. Earle of the Florida Experimental Station, the average being taken from 15 varieties analysed by him:—

CHARLES SHAND.

* The TROPICAL AGRICULTURIST *

◇ MONTHLY. ◇

Vol. XVII.]

COLOMBO, DECEMBER 1ST, 1897.

[No. 6.

“PIONEERS OF THE PLANTING ENTERPRISE IN CEYLON.”

(*Second Series.*)

CHARLES SHAND:

PLANTER AND MERCHANT:—1842 TO 1890.

NOT many colonists now living have had a longer connection with the island of Ceylon than CHARLES SHAND, the subject of our brief memoir. Mr. Shand's grandfather, a native of Edinburgh, migrated to Liverpool to establish his

sons in business, and there they engaged in the West India trade in sugar, &c., so that in the previous generation the family had been connected with tropical products, though not with the island of Ceylon.

Charles Shand's father and mother (Francis and Mary Shand) were both Scotch: the former born in Edinburgh and the latter in Aberdeen. Mr. Charles Shand was born in Liverpool on the 20th November, 1819. He was educated in private schools until he was fifteen years of age, and was then apprenticed for seven years to one of the principal Brazil mercantile firms in Liverpool. Mr. Shand was well grounded in his school, and we remember his challenging an English Public School lad of the present generation to compete with him as an old man, in his acquaintance with standard classics. Mr. Shand is one of the very few surviving free burgesses at Liverpool not disfranchised by the Reform Bill. "At the termination of my apprenticeship in January, 1842," he says, "I took up my freedom as a burgess of Liverpool, as I was entitled to do,

from having served free men for seven years. I could have claimed it by birth, as I was born 'free' of the city. The firm I served wished me to remain with them; but I decided, if my relatives would support me, to go out to Ceylon as a coffee planter, being induced thereto by the reports of my uncle, Sir William Reid.

"My father had died when I was very young, so I had to look to his brothers for assistance to carry out my wishes. This was granted, and I left for Ceylon at the beginning of February, 1842, arriving by the overland route in the middle of April, a fact which exemplifies the striking advance which has been made since the early years of Her Majesty's reign in shortening the time occupied in journeying to the East, railways and ocean steamers being then in their infancy. I went through France by diligence to Marseilles, and there embarked in a steamer which touched at all the Italian ports to Lyra, one of the Greek Islands, and then on to Alexandria. After staying there a few days, I went to Cairo *via* the Mamoudieh Canal and the Nile in a little steamer called, I think, the 'Jack O'Lantern.'* I remained a week at Cairo, visiting the pyramids, and going to the top of the highest, and seeing all that was to be seen in the neighbourhood of Cairo. I was accompanied by a young

* Just as we did nearly nineteen years later, in October, 1861, on our way out to Ceylon!—Ed. T. A.

man of about my own age, who was going to Bombay. He had been appointed Chaplain to the 2nd Queen's Regiment; he was a very good fellow, having been educated for the Medical profession, but qualified for the Church, on the offer of an appointment. However, all this has nothing to do with my experiences of Ceylon, but it illustrates the length to which Memoirs of my life would extend, if I amplified the incidents upon which you wish me to expatiate." [We only regret that Mr. Shand has not given some more of his travelling experiences in these early days, especially of his journeying through France.—ED.]

"We left Cairo at 5 o'clock one afternoon, in the middle of March, travelling on donkeys, as all the vans were at Suez waiting for the arrival of the steamer in which we were to take our departure for Bombay. We reached Suez at 8 p.m. the next day, having made the 84 miles' journey in 27 hours! We changed donkeys only once. We arrived more dead than alive; but I insisted upon our agreement not to stop more than two hours at the half-way house, being adhered to, much to the indignation of my companion. By travelling in this way, instead of waiting for the vans to arrive at Cairo, we secured the choice of berths in the Government steamer.

"On arriving at Bombay I met the Messrs. Worms and Rigg, and we were fellow-passengers to Colombo in the Ceylon Government steamer 'Seaforth,' commanded by George Steuart, who afterwards became the head of the firm of George Steuart & Co., under the *ægis* of his brother James, who was the Agent of Arbuthnot & Co., of Madras, and Master Attendant of Colombo."

What follows conveys a vivid description of coffee planting in the "forties":—"On my arrival," Mr. Shand continues, "I travelled about the country (Kandy and Badulla) in company with my uncle, the late Sir William Reid. After looking about me in search of land, I went down into Sabaragamuwa *via* Haputale; and, after visiting the different parts of the district, I bought 600 acres of land and settled down at Rakwana, which I planted as a coffee estate." [The joke used to be that Sir Wm. Reid—an experienced Demerara coffee planter—who chose the finest block of land in the country for his own estate, in Spring Valley, Badulla,—selected a very poor lot for his nephew and passed through all Haputale in order to settle on much inferior Rakwana; but the fact was that there being no roads, the frightful distance of Haputale from any port, and the difficulty of getting coolies to stay there in the early 'forties,' drove the prospectors nearer to Colombo.—ED.]

"There was a good deal of sugar planting going on at that time. I bought 1,200 acres of land in the Rayigam Korale with the intention of trying sugar planting, but afterwards gave up the idea and sold the land. Before I planted the sugarcane, I ascertained that the climate and the soil of Ceylon was not adapted for the profitable cultivation of sugar. It grew well enough, but the yield was only about 2 tons an acre for the first year, and afterwards even less. The canes would not ratoon and required replanting every two or three years. Consequently, all the sugar estates came to grief, and about half a million sterling was lost by the planters. I went to Colombo to wait until the Rakwana land was ready to be opened. There was no way of getting to the land at Rakwana, which was about 90 miles from Colombo, but by walking. The roads were impassable for horses for want of bridges. I commenced to open the Rakwana land at the end of 1842, and planted it in June of the following year, when I was joined by my brother, Mr. T. L. R. Shand. I remained a coffee planter until 1848, when, owing to the commercial panic of the previous year, all sorts of produce went down to a very low point. I then commenced business as a merchant, and in 1850 I established a firm in Madras, sending my brother there to manage it. I continued in business in Colombo until 1862, when I came home to England and remained at home till 1875, when from circumstances well-known I went out again for three months. I returned again with my family in 1876, and remained there till 1890, and have now been at home seven years."

In 1849 Mr. Shand went over to Cochin, passed over the Nilgiris, stopping at Ootacamund about a month, and paid his first visit to Madras. The travelling dawk was in those days a very comfortable and easy way of travelling, all that was necessary being to deposit £25 with the Government at the Post Office, and they put all the relays of bearers on the road at the traveller's disposal, and he never had any trouble. Mr. Shand evidently had a very pleasant recollection of his journey by dawk down from Madras to Tuticorin, where he embarked on a native boat for Ceylon. The boat being, however, unable to make headway against the S.-W. monsoon, they had to put back, and on the return voyage—[tell it not to Mr. Harcourt Skrine!—were shipwrecked on Hare Island. Mr. Shand had therefore to dawk down to Pamban and go from Pamban on to Negombo. In 1853 Mr. Shand married Miss Symons, daughter of Mr. Symons (father of the present popular Secretary to the Colombo Chamber of Commerce). All the nine children of the marriage are still alive.

Mr. Shand in 1855 or 1856 took a contract from the Government to construct a bridle road from Rakwana to Pelmadulla, a distance of 16 miles, for the sum of £5,000, undertaking to buy 5,000 acres of forest land to provide the money. He afterwards sold this land which formed the Aigburth, Gilgarron, Deveronside and several other estates. At one time he held the estates of Springwood, Barra, Everton and Rangweltenne, but has sold them all with the exception of Rangweltenne:—"Everton to the Gem Notary" in 1870 and Springwood and Barra to the Asiatic Produce Company in 1889, and the latter have recently sold to the Tea Corporation of Ceylon.

Like everyone else Mr. Shand and his family were hard hit by the fall of King Coffee, but they were among the first to convert their plantations into tea. They also went in for cinchona which was only too successful, so much being produced by the colony that it became an unprofitable cultivation.

—

Mr. Charles Shand was one of the most enterprising, long-headed merchants that ever came to the East. His natural buoyancy and equableness of temper in prosperity or adversity stood him in good stead in any time of excitement or speculation such as followed on the American Civil War. We have heard that Mr. Shand's first happy stroke as merchant was in buying up all the native coffee available in Ceylon at a time when it was very low in price (in 1849), shipping it (of course *via* the Cape) to London where, seven or eight months after, it was sold at a splendid profit, coffee having risen in price as Mr. Shand had anticipated. We come next to the Civil War (1861-63) when Mr. Shand through his Madras and Colombo Firms made a rapid and large fortune by his dealings in Tinnevely cotton, the cotton crop of the Southern States being shut in by the blockade. Almost our first bit of work in Colombo in November 1861 was to frame and print a Telegraphic Code for Mr. Shand—three copies only—for Tinnevely cotton. "Up to what rate shall we go per lb.?" "Oh sixpence is ample." "Just as easy going to a shilling."—"The day Tinnevely cotton is at 6d., I'll retire":—so spoke Mr. Shand when that staple was 2½d.; but within six months, if we remember rightly, our "shilling" code was useless, for Tinnevely cotton had run up to *eighteen pence*! Mr. Shand had cargoes by sailing vessels sold half-a-dozen times over between Tinticorin and London. He was by far the boldest buyer in Colombo at that time; after him coming Messrs. E. J. Darley (Darley, Butler & Co.); Alex. Gibson (Alstons, Scott & Co.); and J. C. Fowle—all of whom made ample fortunes in cotton. Mr. Shand had some strange experiences:—one of the

most curious followed on his agreeing to go partners with a big Madras landed proprietor in a cotton cargo. When the ship was half-way home, a rumour spread that the blockade was broken. Mr.—came in terror and tears to Mr. Shand to say he would be ruined, that he, a planter, &c., had no right to go speculating in cotton, and implored to be released of his share. Mr. Shand agreed. The blockade rumour proved false; the cotton got safely home; and Mr. Shand (then in London as well as his quondam partner) stood for an enormous profit, when he received a formal demand from Mr.—for his half share. He took the letter and papers to Mr. (afterwards Sir Hugh) Cairns, who decided that although morally Mr.—had not a leg to stand on and was besides a rascal, yet legally (through want of formality in cancelling the agreement) he would be certain to gain in any Court. Accordingly, Mr. Cairns advised Mr. Shand not to go to law, but to pounce down on Mr.—, give him a bit of his mind, and then offer him so much down. Mr. Shand did so; he called on and abused Mr.— up and down, and indicated how he would expose him in Court; but finally said "to be done with it I offer you"—say £5,000 (perhaps half or one-third of the half profits), and Mr.—jumped at the offer rather than face exposure!

During the interval between the failure of coffee and success of tea, Mr. Shand—even when well on to 70 years—during his last stay in Colombo, was indefatigable in experimenting with new products, among the rest with fibrous plants; and he tested, with machinery of his own invention, nearly every fibre-yielding plant in the island with the result that our little Ceylon aloe (*Sansevieria Zeylanica*) gave the best results, though not enough to make it pay at that time.

Another curious experience of Mr. Shand was his gifting (as a pleasant fancy) his Rakwana Coffee estates to Mrs. Shand when leaving Ceylon with his "cotton" fortune in the "sixties." Most fortunate accident! For when through business complications with the Messrs. Collie, London, Mr. Shand lost all that fortune, the despised Rakwana properties came in very handy as being free of his personal estate!

During his long residence in Ceylon Mr. Shand had never more than a day or two's illness, a fact which he attributes to the climate being suited to those who are able to move about the country or to those in Colombo who take plenty of exercise combined with moderate living.

Mr. Shand himself was one of the most active as well as cheerful men we have ever seen. His brisk step, cheery voice and pleasant laugh were missed in the Fort of Colombo when he left for England in 1863; and the same was

true when he finally quitted Ceylon in his 71st year in 1890. He is now in his 79th year and continues to take a great interest in Ceylon affairs, though his health will not permit of his moving about as freely as he did ever since he went home until very lately. He carried on a brisk correspondence in the *Observer* some months ago on the Currency question, pointing out how China Tea must score at the expense of Ceylon, with silver and exchange so much in favour of the former. The latest letter we have had from the veteran was still clearly written and hopefully expressed. For industry, cheerfulness and indomitable pluck, few Colonists ever came to Ceylon who equalled Mr. Charles Shand: may his shadow never grow less!

MAY TEA BE PROFITABLY GROWN IN THE (AMERICAN) SOUTHERN STATES. ?

It is not a question whether individual plants may not be successfully grown so as to present interesting and beautiful objects, in landscape or other gardening, nor whether small patches of the hardier varieties of tea may not produce sufficient leaf to supply the limited demands of a household, or even those of a country neighbourhood. Those problems have been satisfactorily answered long ago, in several of the Southern States. The price of labor and the yield per plant are not important factors under the latter conditions. Several large profits have been reaped on the imported commodity before it is sold over the village counter; and no account of the value of the labor expended in raising and preparing the domestic article is apt to be taken.

But the problem to whose solution much time and attention have been expended at Pinehurst, viz: the economical raising of tea on a comparatively large scale, is confronted by several serious obstacles, and much more than the past few years must be devoted to experimental work before a satisfactory solution may be obtained.

First and foremost is the difference in the price of labor between the tea-producing countries of the Orient and the Southern States of America. It costs almost as much to pick, with us, of fresh leaf sufficient to make a pound of tea as it does to raise, pick and pack the same quantity of by far the larger part of the teas sent to us from Asia. There are, therefore, two alternatives presented to the would-be American tea-grower; he must raise the quality of his product above that of the cheaper Oriental grades, or he must reduce the cost of production below that attained by us. The former course has been steadily maintained at Pinehurst, and with promising results.

The establishment of a productive tea garden involves very considerable expense. A well appointed garden, of good quality and of large leaf production, with few vacancies and of vigorous growth, a sufficient body of reliable laborers, and a suitably equipped factory, cost a great deal of money and attention. That these conditions are essential in the production of good tea must readily appear on a little reflection. A well appointed tea garden implies favorable conditions of soil and exposure to the sun with protection from windy blasts and the avoidance of stagnant water about the roots of the plant. *Good quality* means that the plants have been raised from the best seed attainable or capable of being grown in the local climate. It is certainly necessary to distinguish at least three sorts of tea plants. The Assam unquestionably leads. It derives its name from the north-eastern province of British India which was wrested from Burmah early in this century. It was found growing to the height of thirty

feet in the dark, steaming jungles along the banks of the Brahmapootra river, where the atmosphere was always damp and frost unknown. Its leaves are bright green and large, often attaining a length of seven or more inches, and broad in proportion. Few regions elsewhere appear to be favourable to the growth of this variety, although long ago the forests of those jungles have given place to well ordered tea gardens, where the indigenous plants bask in full sunshine—a requisite for the remunerative production of tea crops. The attempt is being made at Pinehurst to cultivate some of this variety; but the severe weather (15° F.) to which this section of South Carolina is liable, makes success less than probable. It may be that fully hardened and woody plants are capable of enduring such extreme cold, and that by grafting or otherwise, a slightly lower type may be obtained for successful use. At the other extreme is the Chinese variety. Not that all or even the greater part of Chinese tea plants should fall under this category, for unquestionably very many deserve far better treatment; but as the type exists to a considerable extent in China, and especially in its colder provinces, the name may be retained. This variety is a low, bushy shrub, slow of growth, adapting itself to a great range of climate, and capable of withstanding frost, snow and ice. The leaves are of a dark green color, tough and small, *i. e.*, from two to three inches in length and quite narrow, (lanceolate shaped). This stunted and generally unprofitable description of tea plant is supposed to be the result of the exposure of the better varieties for centuries to dry and cold climates, and to a lack of proper cultivation.

Intermediate between the Assam and Chinese types stand the so-called "Hybrids," and reproducing in their countless varieties the characteristics of both the parent sorts. Strictly only few of them have been obtained by the direct hybridization of the before mentioned varieties; most of them are the result of endless crosses of different kinds, as also of the effect of climate and cultivation. It has been observed at Pinehurst how few tea plants are not susceptible of great improvement in form, productiveness and quality by liberal cultivation; and that gardens of widely different origins exhibit, under the same treatment, a tendency to produce a local type of leaf, with marked and distinctive characteristics.

It is generally held, especially by English authorities, that those hybrids which stand nearest, by origin and in their nature, to the Assam, are to be more highly prized. There are substantial reasons for our advice to plant only the best seed that can be grown in each locality. The Assam plants produce, in their own climate, about twenty *flushes* a year, whereas the average number of pickings in China do not exceed more than three or four. And it may be well to here explain what is meant is meant by a "flush." The work of the tea planter is to produce from the seedling and as rapidly as possible a vigorous bush of from two to five feet in height, according to the variety of seed. He then proceeds to deplete the plant of by far the greater part of its foliage, which is usually done in the cold season. Nature makes a prodigious effort to restore the natural equilibrium between roots and foliage, and with the advent of warmer weather, throws out from every branch a vast number of tender shoots and leaves. The planter immediately plucks off as much of this young foliage as his experience has taught him to be wise, *i. e.*, without injury to the vitality of the plant or loss to the subsequent pickings. For the struggle between him and the plant goes forward through the entire season. These successive crops of young leaf are termed "flushes." The wise planter will not strip the plant of young foliage at any picking, and thus there is a steady gain in the size of the tea plant during the growing season. With the return of cold weather, a more moderate pruning is resorted to, severe pruning being enforced only every three or four years. The length of years that a tea plant can endure this struggle is uncertain, but it should, under favorable circumstances, produce at least ten good yearly crops.

Large leaf goes further than small leaf, (both being tender, for that is an indispensable condition for making good tea.) The young plants, whether grown from seed *in situ* or transplanted seedlings from the nursery, should fill out the gardens at regular intervals, determined chiefly by their expected growth, varying from three by four to six by six feet, where plowing is used. Vacancies occur from the death of individual plants; they should be as few as possible, as they waste the land and increase the labor of cultivation and gathering. A vigorous growth depends upon the productiveness of the variety of plants used, on the climate, the richness of the soil and the cultivation. As regards temperature, the best climate for tea is a warm one, ranging during the year from 45° to 90° F., and without sudden and great variations or severe wind storms. The rain-fall should be abundant and evenly distributed throughout the year. But it is essential that copious rains and frequent fogs should occur during the warm season when the flushes are produced. The rain-fall in the countries best adapted for raising tea ranges from 75 to 150 inches and more per annum. Nevertheless it is possible to remuneratively grow tea in medium climates with lower averages of both heat and rain-fall. Indeed, were this not the case, it would be idle to attempt the cultivation here with an average temperature of 65° F., and an annual rain-fall of 56 inches. The question then probably turns on the two points already mentioned, viz.: the dearthness of labor and the liability to extreme cold in the winter. The occurrence severe cold in the winter may so weaken the vitality of the choicer sorts of tea that the crop of the following season may be reduced by the amount per acre that marks the limit of profit. An average production per acre of Indian and Ceylon gardens, in good bearing, is about 400 pounds of cured tea annually; although instances are not infrequent of 700 to 1,000 and even more pounds under the most favourable conditions of cultivation and climate.

The tea plant is an enormous feeder. If the soil does not afford abundant food, artificial enrichment must be resorted to. Liberal fertilization augments not only the quantity but improves the quality of the leaf, as has been demonstrated experimentally at Pinehurst, especially on poor and medium lands. The picking of the leaf on a garden of twenty-five acres will keep a small force of say twenty children almost continuously busy during the season. With patience and attention, the colored children in the Southern States quickly learn to perform the task satisfactorily. In the earlier flushes, they are taught to pick only the unexpanded leaf bud at the end of the shoot (the "Pekoe tip,") with perhaps the one or two next and very tender leaves. Later in the season, the number of leaves to be picked may extend to three or four. It is a pretty sight to see the gathering of the leaf by the children.

A suitably equipped factory is indispensable to even a moderate-sized garden. For the present only black teas are made at Pinehurst; and, consequently a brief description of what is requisite for their manufacture must suffice. The first step is the withering of the fresh leaf. This is effected by thinly spreading out the leaf on floors or trays, so that every pound shall cover about ten square feet. As each pound of finished tea represents four and one-fifth pounds of fresh leaf, it will be seen that an output of one hundred pounds of dry tea per diem requires about four thousand square feet of withering surface—in itself an expensive item. The purpose of withering is to render the fresh leaf susceptible of being rolled without breaking. As it comes to the factory it is crisp and elastic; it crackles when compressed in the hand; when bent, it immediately resumes its former shape. Withering requires a light, airy room, but it is better to exclude direct sunlight. A few hours sometimes suffices for the change, but usually a whole day's exposure is necessary. When sufficiently withered the leaf has lost its elasticity and feels like an old kid glove; no longer will it crackle when compressed, nor will it regain its shape.

Fresh leaf has neither distinctive taste nor odor. Withered leaf has a faint odor; peculiar, but not suggestive of the finished tea. By rolling (either by hand or machinery) the oily cells in the leaf are broken up and the juice expressed upon the surface of the leaf. There it becomes foamy from the action of the air and the continued rolling. An oxidation begins, which is prolonged by exposure to the air. By rolling and oxidation (formerly and erroneously termed fermentation) are developed the strength and, in part, the flavor of the tea. The rest of the flavor and the fragrance are the result of the final process of "firing" or drying. It has been found advantageous to substitute machinery for hand power in most of these operations, especially where the production is sufficient to warrant the expense of buying and erecting the especially devised machines. And aside from economy in production, the greater uniformity of product and the more attainable cleanliness of the manufacture are commendable features. In the rolling of tea leaf, a capable man can handle thirty pounds a day; a "Little Giant" rolling machine can do as much in half an hour, and takes the labor of one mule to accomplish it. The total cost of a factory suitable for the daily production of fifty pounds dried tea may be estimated at \$1,500 to \$2,000.

It has been thought advisable to dwell on the expensiveness of tea production, as letters are constantly received asking for such information. There should be added the loss which follows from impairment of seed on the long journey from the East, whereby only one box in four comes to hand in good order, as also the remuneration of the skill and attention which must patiently and constantly oversee every step in the growth and manufacture of this product. And thus, even if the raising and manufacture of tea in the United States be divested of all fancy, and the utmost economy be practiced, it will be seen that the obstacles and expenses to be overcome are very considerable; indeed so considerable that any serious competition with Asiatic producers on the lower and medium grades is simply out of the question. What, then, are the grounds which justify the continuance of experimentation in this direction? And the only satisfactory answer that can be given is, that thus far experience appears to justify the original hope of our ability to grow high grade teas remuneratively. Thus far, we have established at Pinehurst very fair tea gardens from choice imported Chinese and Japanese seed. From them, we have produced both the green and black teas, of a quality which readily commands one dollar or more in the retail market. The gardens have few vacancies, and the plants have a luxuriant growth. There are also a number of gardens raised from hybrids that were introduced many years ago into this country by the national government. Unfortunately they exhibit the effect of neglect, in having largely relapsed towards the Chinese type. They require rigorous pruning, often the extirpation of refractory individuals, the promotion of a more favourable secondary growth, and liberal cultivation; under these conditions they give excellent results. Other gardens of Formosa, Assam, and the best hybrids from India and Ceylon are yet too young to afford reliable data. There can be no question of the luxuriant growth of the hardier sorts, nor that the quality of the product and its reception by the public entirely meet with our fullest anticipations. But not enough experience has been gained to form an estimate of its productiveness per acre (or per plant) of the gardens; nor can any positive statement be given as to the success of the two lines of experimentation to improve the general quality of the plants, by importing different varieties of the more tender sorts, until that variety be found which combines the utmost quality with the ability to stand this climate, or by direct propagation by cuttings and grafting to reproduce the best individual plants in the already established gardens. It was to be expected that our experiments must encounter many obstacles and cause many disappointments. But there has been

enough success thus far to warrant their continuance. Ultimately it is hoped to attempt the manufacture of those very highly esteemed and priced teas which are rarely met with outside the countries where they are grown; and simply, because of a light "firing," they do not stand distant transportation. They should be drunk shortly after manufacture. This is a field where the American grower need fear no competition from the Orient. Such teas must demand a high, very high price; but if better than can be otherwise obtained, there will be no scarcity of buyers.

CHARLES U. SHEPARD.

Pinehurst, 1896.

COFFEE PLANTING IN MADAGASCAR.

In 1871, the late Mr. Alfred Guenot, of Vatmandry, tried large plantations of coffee in Mahanoro District. The plants grew very well, and if that gentleman had succeeded in the enterprise he would have certainly been one of the richest men who ever attempted serious planting in Madagascar. Some time after, in 1872-73, a kind of fever passed through the district of mahanoro, the disease unknown until that time, acted so strongly on the brains of the inhabitants, that an epidemic immediately broke out: it was planting coffee; almost every one wished to plant, and planted coffee; that plant responded to the desire of the inhabitants and grew luxuriantly; unfortunately this did not last long. What often happens in such cases soon occurred, namely, deceptive appearances, and then disillusion. Coffee had been, it is true, planted on a large scale, but no one provided for the means of maintaining it. *Planted artificially, the care of bringing up the child was left to Nature alone.* In a short space of time large plantations of coffee had been made, but alas! they did not last long. In a few years, after a few crops all the plantations had disappeared. Almost all the coffee-trees had died. No one searched for a remedy, or to discover the cause of the disease. All contented themselves with saying, "The coffee plantations are destroyed by a disease." Only one planter, Mr. Jean Comte, now in Tamatave, was in the habit of manuring the coffee-trees yearly. Well, he prescribed his plantation, and we remember, long after the disappearance of the other plantations, having twice accompanied him on his estate situated at Ambodiriana Lohariana and saw the coffee-trees in a very fair state of vegetation. When the late war took place and Mr. Comte was obliged to leave Mahanoro, his plantation was in full crop, while long before there remained only stumps of trees on the estates of the other planters. In our opinion, the coffee-tree was destroyed by a disease which could be summarised by these words: *want of nourishing elements.* We think that the coffee-tree could be planted and would succeed on the condition that the plantation be manured yearly, even twice a year, if possible. The soil of this country possesses an incredible degree of vegetation, but, by the very fact that the vegetation is so active the soil becomes impoverished quickly. *Since artificial plantations are made, Nature ought also to be aided artificially.* The late M. Alfred Guenot, who had lost so much money in planting coffee, was of opinion that coffee ought to be tried again and was preparing to do so, when unfortunately he died. The same sort of coffee: s that which was cultivated at the time could, we believe, be planted afresh—the tree is not sick, since on all estates where coffee was planted, it is observed that a few have escaped owing, undoubtedly, to having been planted in richer veins of soil. In the villages and yards one notices a few coffee-trees growing nicely, probably taking their nutritive principles from the manure formed naturally in these places. It is a good idea to introduce the coffee of Lileria here, but it is no reason why the ancient sort should not be planted again. In 1880 the coffee in white shell was worth 3 dols. per 100 lb.; at the present time, one could hardly, by offering 11 dols. or 12 dols., obtain 100 lb. of the same produce. Most of the foreign community, if not all, make use of tea now.

We have also observed that coffee flourishes here in places sheltered from winds, and ever so little *umbraeous*. We believe that the plant would do very well as interlineary plantations.—*Madagascar News.*

COFFEE CULTIVATION IN BRAZIL.

The following on the subject of the cultivation of Coffee in Brazil, published in the *Revue Coloniale*, is taken from a report addressed to the Minister of Foreign Relations of France by Mr. Viener, on his return from South America:—

The largest coffee-planting region is found between latitudes 18 degrees and 25 degrees south; but it extends much farther north, and coffee raising is carried on in an immense territory, embracing 25 degrees of latitude and 24 degrees of longitude.

In the beginning of this century Brazil exported only a very small quantity of coffee, but now it is the principal coffee-producing country of the world.

The following statement shows the increase of the Brazilian coffee trade since 1,800, from the ports of Rio and Santos alone in bags of 60 kilograms (133 pounds) each.

1800	13
1817	66,985
1820	97,489
1830	484,222
1840	1,037,981
1876	3,765,122
1895	6,508,768

In 1895 the crop was estimated at 7,000,000 bags; in 1896 it was even larger.

The coffee plant is not indigenous to Brazil, but it is today completely acclimated. One finds, it is true, in the forests of Botucato (State of Sao Paulo) a so-called wild coffee plant (*Coffea anarello*), but they are without doubt plants that have come up from seeds carried by birds or monkeys. The cultivated variety is called in the country *coffee vermelho*. The height of the plant varies from 2 to 5 metres and the stem measures from 40 to 70 centimetres in circumference.

The processes of cultivation vary according to the locality. Thus in the province of Ceara, according to a pamphlet by Mr. Joh, quoted from by Mr. Viener, the coffee plant is always started in green-houses. The roots are transplanted at the age of two years, preferably from January to April, and are planted at a distance of from 10 to 12 palmos (the palmo is equivalent to about 9 inches). They begin to yield at four or five years. The season for gathering the crop is not always the same; on the other hand, it has quite a long duration, varying somewhat according to the heaviness of the rainy season, which generally begins in May or June and ends in August.

The beans are placed on a paved floor (uncovered), called in the country *fachine*, and the drying lasts from thirty to thirty-five days. In the State of Ceara the old system of decortication by grinding by millstones (*rodieros*) turning in a stone trough is still employed. This method leaves much to be desired, for many of the grains are crushed by the weight of the stones. The cleaning and burnishing are done usually by hand.

In the States of Sao Paulo and Minas Geraes the cultivation of coffee occupies vast areas, and the treatment of the coffee after the crop has been gathered is done in a much more perfect manner than in Ceara, by the most improved machinery.

The largest *fazenda* (plantation) in Brazil, and perhaps in the world, is the Dumont plantation (State of Minas Geraes) established by a Frenchman, whose name the plantation still bears. The total extent of the property is 30,000 hectares, 6,150 of which are planted in coffee. The number of plants in 1896 was 4,718,000.

The cultivation is carried on by Italian emigrants, of whom there are 8,000 employed. Each year the extent of this plantation grows, and the production becomes larger and larger.

In 1895 the yield from the Dumont *fazenda* alone amounted to 4,100,000 kilograms, and that of 1896. rose to 4,500,000 kilograms. This plantation was sold three years ago to a Brazilian company for the sum of 12,000,000 francs.—*The American Grocer*.

LUCERNE (ALFALFA) CULTIVATION.

Extract from 'Hand-Book of Experimental Station Work,' published by the Department of Agriculture, United States, in 1893 (pp. 10—11.)

LOCALITIES SUITABLE FOR CULTIVATION.—A perennial forage plant, resembling clover in its feeding value, habits of growth and effects on succeeding crops. Under favourable conditions it will live from eight to fifteen years and does not run out as clover does. It has long been cultivated in Europe and is grown quite extensively in California and some of the other Western and Southern States. It seems probable that it may be introduced with advantage into many parts of the Southern States east of the Mississippi, and over a wide tract of the more arid regions of the south-west. It has been grown successfully for several years at the station at Geneva, New York, but in recent experiments on thirty farms in different parts of Vermont, it was very largely winter-killed.

While a southern climate is more favourable to Lucerne, numerous experiments have shown that it will do well in many localities in the Northern States, and, when established, will produce from three to five crops each season for a number of successive years. "Lucerne is specially adapted to dry climates and withstands drought much better than ordinary clovers." For this reason it is largely relied on in Colorado and California, especially where irrigation is used.

A NITROGEN-COLLECTING CROP.—Lucerne is one of the plants which collects Nitrogen from the air. It also gathers a considerable amount of Phosphoric Acid and Potash. At the New Jersey station in two years Lucerne grown on 1 acre collected 553 lb. of Nitrogen, 98 lb. of Phosphoric Acid, and 586 lb. of Potash, valued at 124 dollars.

If Lucerne and its products are properly utilised on the farm, it cannot be considered an exhaustive crop, but rather one which transforms the raw materials in soil and atmosphere into products for man's use.

SOIL PREFERRED.—*Culture.*—Lucerne prefers a light sandy or loam soil, with a sub-soil through which its long roots can penetrate. In some cases its top root down 12 to 15 or even 20 feet. At the New York station, however, Lucerne has been successfully grown on a clay soil. On such a soil greater pains must be taken to secure a good stand, but, when the plant is once established, the character of the sub-soil is of more importance than that of the surface soil. Use fresh, pure seed. Sow at any time when the ground is in suitable condition, and when there will be time for the plants to become well established before they are subjected either to drought or extreme cold. The soil should be thoroughly prepared and the seed sown at the rate of 15 to 20 lb. to the acre. If sown broadcast, about the latter quantity will be required; if in drills, the former amount will be sufficient. In the north spring seeding is advisable, but in the south it is better to sow in the autumn.

IRRIGATION.—In regions where irrigation is necessary, the Colorado station advises that the water should be applied to Lucerne before cutting, because thus the reaper does its work more effectively, and the growth of the succeeding crop is stimulated. A relatively large amount of moisture is required the first year in order to secure a good stand.

HARVESTING.—Lucerne should be cut during the first period of good weather after the blossoms begin to appear. If allowed to stand too long, its stalk becomes hard and woody, and succeeding crops are likely to be diminished. If designed for hay, it must

be carefully cured and housed, for otherwise its leaves will drop off and only a mass of bare stalks be left.

VALUE AS A FEEDING STUFF.—During a single season Lucerne furnishes a large amount of nutritious green forage relished by all kinds of stock. It should be partially wilted or mixed with hay or straw. In the dry regions of the west it is much used for pasturage, especially in the autumn, but there is more or less danger that it will cause the cattle to bloat or that the plants will be killed by close pasturing. Cattle, sheep, and horses relish Lucerne hay and seem to thrive on it.

Chemical analyses and digestion experiments show that Lucerne compares very favourably with red clover both as green fodder and as hay. It may be used either for fattening or for milk. To secure a well balanced and economical ration, Lucerne, which contains a large proportion of *protein*, should be fed with corn, wheat, oats, straw, root crops, etc., which contain relatively large amounts of the other food ingredients (carbohydrates and fat). In many instances farmers might profitably raise Lucerne as a substitute for the wheat bran, cotton-seed meal, and other materials which contain large amounts of *protein* and which they are now buying in order to utilise the excess of carbohydrates produced in corn and other crops.

DISADVANTAGES.—(1) It is not easily established; (2) it is less hardy than clover; (3) if allowed to grow too long its stalks become hard and woody; (4) except in dry regions cattle cannot be safely pastured on it; (5) it requires peculiar treatment to make good hay.

ADVANTAGES.—(1) When established it does not run out; (2) it withstands drought much better than clover; (3) it grows rapidly and may be cut early in the season; (4) it gathers a large amount of nitrogen from the air as well as from the soil, and is therefore very valuable as a fertilising crop; (5) it furnishes several large crops of green fodder each season; (6) when properly cured it makes an excellent hay; (7) it is relished and digested by all farm animals and is an excellent flesh and milk producer; (8) it makes muscle rather than fat, and is therefore valuable to use with corn and other fat-producing crops to make a well-balanced ration for cattle.

In brief, experience at the stations and elsewhere indicates that Lucerne is valuable as a feeding stuff and as a fertilising crop, but that it requires peculiar conditions of climate and soil for growth and careful culture and curing to make it a profitable crop. It is worthy of repeated and systematic experimental tests by farmers, even though in some regions and on some farms it should prove a failure.

DISEASES.—(*Pseudopeziza medicaginis*).—This fungoid disease is found in nearly every place where Lucerne is grown. Usually it does not attack the plant until the second year's growth when the plant is able to survive the disease. Sometimes, however, it completely destroys seedling plants. The disease shows itself as minute dark-brown spots of irregular shape upon the green or discoloured leaflet. The centre of each spot forms a small pustule. In this are developed the spores, which are set free by the breaking of the epidermis. The disease readily survives the winter and may develop year after year in the same field. In serious cases covering with straw and burning alone stopped the disease. It may be held in check by frequent cuttings.

LUCERNE ROOT-ROT.—(*Ozonium auricomum*).—The fungus causing this disease has been identified as the same as that causing the "root rot of cotton." It attacks the crown of the plant and works down for 6 to 10 inches, completely killing it. In the field the disease spreads in almost a perfect circle, at a rate of 50 to 60 feet during the season, killing every plant. It is thought that sowing salt plentifully or applying kerosine over the infested spots will kill it out, thus preventing further spreading. The disease is worst in dry, hot weather.

In the Appendix to the *Handbook of Experimental Station Work* (pp. 386, 388 and 397) the following is

given as the averages of the 23 chemical analyses of Lucerne:—

	Water.	Ash.	Protein (N x 6.25).	Fibre.	Nitrogen-free extract.	Fat.
As GREEN FODDER.						
Fresh air-dry material	71.8	2.7	4.8	7.4	12.3	1.0
Water-free substance	Nil.	9.4	17.1	26.2	43.9	3.4
As HAY AND DRY COARSE FODDER.						
Fresh air-dry material	8.4	7.4	14.3	25.0	42.7	2.2
Water-free substance	Nil.	8.1	15.6	27.3	46.6	2.4

Fertilizing Constituents of Feeding Stuffs:—

	Moisture.	Ash.	Nitrogen.	Phosphoric acid.	Potassium oxide.
Green Fodder ...	75.30	2.25	0.72	0.13	0.56
Hay or Dry Coarse Fodder ...	6.55	7.07	2.19	0.51	1.68

To contrast with the above Sorghum Fodder may be here shown from the same table of analyses of Fertilizing Constituents of Feeding Stuffs:—

	Moisture.	Ash.	Nitrogen.	Phosphoric acid.	Potassium oxide.
Green Sorghum Fodder ...	82.19	...	0.23	0.09	0.23

—Agricultural Ledger.

THE LONGEVITY OF SEEDS.—M. Charles Naudin contributes to the *Bulletin* of the Société Nationale d'Acclimation de France a paper on "The Longevity of Seeds, and their Preservation in the Earth." Seeds, says he, are known to remain for an indefinite length of time, even for several centuries, in the ground without germinating, owing to atmospheric or other causes. M. Naudin instances, as a case of suspended germination, a packet of earth from the Sahara, which spread over a flower bed, and duly watered, was found to contain seeds of *Helianthemum*, which grew, and bore yellow flowers. The inference is, that an apparently barren region yet contains in its soil seeds which, were the climate to become more humid, would rapidly transform it to one of vegetable fertility and luxuriance. M. Naudin mentions, in further confirmation of his opinions, that in 1895 he received a few seeds from Gaboon packed in some of the soil of that place. This earth, less than two pounds in weight, was placed in a flower-pot, whence, in a fortnight, sprang twenty seedlings all belonging to the *Cucurbitaceæ*. The stems and branches of these plants grew to a length of from 20 to 24 feet, and it is hoped that they will put forth bloom, thus showing the genus and species. From this accidental yield, it is supposed that soil more carefully selected would give still richer results. In the many cases where plants cannot be brought to Europe in good order, where they die on the voyage, or are immature or past their prime, it is suggested that a sample of the earth selected from some likely spot in their vicinity should be sent over in their stead, and might be found to contain fertile seeds of the species desired. If this, says M. Naudin, seems a proceeding based too much upon chance, like that of a fisher casting his net at a venture, this difference may be pleaded: the botanical collector is no more sure of finding what he seeks, but in all probability will obtain something new and acceptable. Finally, it must always be borne in mind how easily packets of earth can be transported from place to place without any attention on the journey.—*The Gardeners' Chronicle*.

PLANTING NOTES.

ORANGE CULTURE IN CEYLON.—We understand that there has been a considerable importation of good orange plants lately for distribution and trial in different districts. The plants are very choice ones and were selected from a special nursery, and that they cost very nearly R500 laid down at Colombo. They were securely packed in small bags, with the nursery soil, and looked quite fresh and green, but without a single leaf. They promise to do very well, and we shall be glad to know results of their successful cultivation up-country. The native orange (by the way, is it indigenous?) like other native products, is not systematically cultivated by the Sinhalese. It is generally believed that oranges grown on the hills are not so palatable as those grown in the low-country, and that the Salpiti Korale, Kotta, and the neighbouring villages, produce the best oranges, as the soil there is best suited for their culture. Up-country, we are told, the plants thrive well, but the oranges do not taste so well as those grown in the low country, though Nuwara Eliya and the Uva Province produce fairly good specimens. Of course, the oranges grown in Ceylon and India are quite unlike those from Australia and the West. Our oranges, however ripe they may be, as a rule preserve their verdant hue and do not take on a yellow one, while the taste is a sharper and more refreshing one than the sweet flavour of the oranges met with in Europe. We understand that a large quantity of oranges are imported into Australia during the summer from Italy and Spain, and there is a growing demand for them in the Colonies. Should, therefore, the experiments now being made up-country prove a success, there should be no reason why Ceylon should not compete in the Colonies with Spain and Italy. It is a pity that a few lemon plants were not imported as well. The Australian lemons are simply exquisite, and they have a much finer flavour than our Ceylon limes. There is every reason to believe that lemons could be cultivated in our island as well as oranges.—The orange fungus is a great pest in some districts: the introduction of lady-bird beetles would speedily stop that.

PLANTING LIFE IN BRAZIL.—Mr. T. L. Villiers, the Ceylon planter who recently proceeded to Brazil as the Manager of the Dumont Coffee Company's estates there, has returned to Ceylon. His description of planting life in Brazil is not attractive:—

"Mr. Villiers went with Mrs. Villiers to the estate, but found the life there rougher than he anticipated and very different to a planter's life in Ceylon. The heat, he says, was very trying, almost as bad as Colombo, and yellow fever was very prevalent in the neighbourhood, so that he managed to get his agreement with the Company cancelled, and left Brazil after a very brief stay. His description of planting life in Brazil is interesting. There are very few English in the country, and they are not popular with the indigenous population. There was a European family on the Dumont Company's property—the Secretary and his wife—but the nearest European doctor was a 16 hours' railway journey away, and the labourer is Italian, with little in common either with the cooly or with the planter. The little narrow-gauge railway that traverses the San Paulo district is the principal means of communication, but there is an accident on it nearly every day, so that, while it is useful for freight, passengers prefer to go round to Rio by sea, as being slower but safer. Brazil coffee growing may be profitable, but is evidently not an occupation for a married Ceylon planter, or for anybody who is not prepared to rough it a good deal."—*Planting Opinion*, October 16.

THE "QUEENSLAND AGRICULTURAL JOURNAL," Vol. I., Part 5, November, 1897.—Contents:—Agriculture, Dairying, The Orchard, Botany, Apiculture, Tropical Industries, Bacteriology, General Notes, Statistics, The Markets, Farm and Garden Notes for November, Orchard Notes for November, and Public Announcements.

GEMMING—AND GEM-SEPARATING.

Ever since we made the acquaintance in London of Mr. W. S. Lockhart, M.I.C.E., M.I.M.E., and saw his patent Gem-Separator at work, we have been anxious to see his invention tested in the Gemming Fields of Ceylon. Quite two years have elapsed since we first heard of the formation of a Prospecting Syndicate in London having a strong Board and ample capital with the object of purchasing and utilizing the Patent Rights of the Gem-Separator for Ceylon. But we have still to learn of actual work having been begun.

It is, of course, quite possible that, taught by his experience in Burma,—where Mr. Lockhart was at one time connected with the famous Rubies Company, and which he left in order to invent and perfect the separating machine he felt to be indispensable to success,—the patentee prefers to make quite sure of his invention, as well as of his position in Ceylon, and of the certainty of getting at the best fields, before he consents to make a start. Delay, therefore, we hope, will only strengthen the assurance of eventual success; for, by recent news, it appears, the time is drawing near when Mr. Lockhart himself proposes to visit the island, no doubt in order to give a fair start to the Gem-Separator and to learn where it can best be applied.

Of the machine itself, though we do not mean at present, to attempt an exact description, we have only praise to give from what we saw of its work. It is simplicity itself. We saw a bucketfull of such clay as our sapphires are found in, mixed up with a handful of small gems, carefully counted, and the whole thrown into the hopper of the machine; and in a wonderfully short time we had the full quota of precious stones deposited in a glass case below the machine, having, through the process worked clear of the clay by their specific gravity. When taken out they were found to be correct in number. So with minute grains of gold thrown into a mass of detritus which seemed to swallow them up, never more to be seen separately; but passed through the hopper and machine, the result was equally satisfactory, and not a grain was missing.

Not only therefore was it demonstrated that masses of clay or gravel containing precious stones or precious metals could be speedily treated in the machine; but that there was the most absolute guarantee against theft, hitherto the chief drawback experienced by all Europeans embarking in the gemming industry in Ceylon. Mr. Lockhart has said that he is prepared to deal with from 50 to 500 tons of gem-bearing earth per day per machine—a quantity ample to test the best fields around Ratnapura, or in the Rakwana and Matara districts. We feel sure that when the trial is made, the result will be satisfactory in bringing to light, and that very speedily, any gems or gold there may be in the soil treated; and we therefore consider that the introduction of Lockhart's Patent Gem Separators will mean the commencement of a new and important development in the history of Gemming—an industry going back beyond the Christian era—in Ceylon.

Since writing the above we have learned from the local Agents, Messrs. Lewis Brown & Co., that a Mr. Goldie was engaged some months ago, to take charge, it is supposed, of the interests of the Syndicate or Company in Ceylon. A call of capital has also been recently made. We may therefore hope for some active steps

erelong; but, unless machines are on their way out, they may be too late for operations during this North-East monsoon, and so lose the best of another year.

SCHOOLS OF AGRICULTURE IN ITALY.

Several agricultural schools have of late years sprung up in various parts of Italy, the most important in the Naples district, says Consul Neville-Rolfe, being that of Portici. The school has been in existence about 24 years, having been originally established by the province, but it was taken over by the State, and re-established by the Royal Charter in 1885. A portion of the disused Royal Palace was given over to its use, the spacious grounds, gardens, and useful group of farm buildings being especially adapted to that purpose. The instruction is conducted by sixteen professors, each of whom takes his own branch of the subject, as chemistry, botany, horticulture, zoology, entomology, geology, farm accounts, meteorology, physics, forestry, irrigation, &c., and lectures upon it. The course occupies three years, after which students who satisfy the examiners obtain the degree of *Laureato Agronomo*, or bachelor of agriculture. Besides the lectures, practical instruction is given in the field, and the making of cheese, wine, and oil is systematically carried on. It is, in short, an agricultural university; 670 scholars have passed through the school, of whom 228 have obtained degrees, and there are 21 freshmen inscribed for the coming year. Most of the laureates become professors in other colleges in Italy, and some have gone to other places, such as Cairo, Buenos Ayres, and San Francisco. One very useful branch of the institution is the exhibition of agricultural machinery, upon which the future of Italian husbandry depends so much, and another, the dissemination of pamphlets by the various professors on their special subjects. Of these last there is a very interesting one by Professor Italo Giglioli, the head of the school, on the importation of Italian fruit into Great Britain. He begins by stating that the total importation of fruit into the British Isles has risen from £5,977,351, in 1880, £7,287,566, in 1890, with a steady annual increase. Besides this, in 1890, nuts to the value of £622,936 were imported. In 1890, only 4 per cent. of the fruit imported into Great Britain came from her own colonies, and 8 per cent. from Italy, but the Professor is strongly of opinion that while the colonies have increased their export to a very large extent, the next decennial period will show that Italy has not been idle, and that with more attention to cultivation, packing, and means of transport, the Italian fruit will obtain a more influential place in Great Britain, which is shown to be the most influential fruit market in the world.—*Journal of the Society of Arts*, Oct. 1st.

PRESENT PROSPECT OF TEA
PLANTING IN FIJI.

Only two estates of any importance have been opened in these islands, *i.e.*, Alpha and what is now known as the Wainunu Estates. The former was started by the late hon. J. E. Mason, M.L.C. When he had to cease planting Arabian coffee owing to its destruction by leaf disease (*Hemileia vastatrix*) in 1884, he turned his attention to the cultivation of tea on high lands at the north end of Taviuni. The altitude was sufficiently high, about 1,000 feet, the land of good quality and the right nature to produce the best quality of tea, a result fully attained by Mr. A. J. Stephens who undertook the management for Mr. Mason.

Unfortunately while Mr. Mason was on a visit to England and acting as Commissioner for Fiji to the Indian and Colonial Exhibition he died, and the finances of the estate going into other hands, while the manager was unable to get suitable and cheap labourers, the plantation, originally about 400 acres, dragged along until 1895, when the proprietors decided to put

no more money into it. Mr. Stephens also thought that the restrictions placed on the employment of Fijians excessive for the minimum pay fixed by law is put at 8d. a task or day or a lump sum of £5 per annum which is absurd, as a man may do no work for it; while the cost of introducing the labourers on to the estate amounted to over £3 each, £1 5s. of which goes to the Government as commutation taxes and stamp fee; generally 10s. per head being also paid to return the men to their homes, while in addition to all this the planter has to feed, supply soap, tobacco, hospital medicines and housing to the labourer. The aggregate cost under these conditions amounted to from 1s. 3d. to 1s. 6d. per day per man according to the system and food supply at the command of the manager; about double the cost of the labour employed at similar work in India and Ceylon! Under these circumstances Mr. Stephens went back to Ceylon and is opening a tea plantation half of which he owns himself.

Of the Wainunu Estates, Masusu had a very chequered career from the start in 1884 through the vagaries of Mr. Barratt's partner. Up to 1894, Mr. Barratt being mainly a working partner, at this time was left with this and Mr. Simpson's Na Dua Estates on his hands, and with better machinery just to hand he hoped even with Fijian labour and their high cost to make the industry pay. Na Dua Estate of 80 acres had just been planted by the late Mr. G. H. Simpson and with the tea planted on Masusu (Mr. Barratt's original work) of 100 acres a surplus would be left for export after two years' operations. Excellent tea has been turned out and the high grades sell well in Fiji. The Pekoe and broken Pekoe are equal to the Ceylon teas the writer has tasted in Melbourne.

On the 18th ultimo, in company with hon. J. M. Borron, the writer paid a visit to these Estates and Mr. Barratt gave us full particulars of his experience at Wainunu. As Mr. Barratt had anticipated in 1895 and 1896 he had a surplus of several thousand pounds of tea, and for 1896 and 1897 he had a larger surplus mainly of low grade teas. A quantity of the first surplus was sent to the colonies and sold in competition with Indian and Ceylon the average price was about the same as that of ordinary Eastern teas which left no margin for the higher cost of production here on account of labour. On all other points the advantage of land, driving power of machinery (by a Pelton wheel), transport (by water), and timber for packing, are in favour of Fiji. Again the consumption of tea in Fiji is from forty to fifty thousand pounds of tea per annum, but only about half this quantity is used of Wainunu tea for the reason, given by Mr. Barratt, that on account of the low grade teas being admitted at the same rate of duty as the better kinds, the very inferior kinds are sent here from the colonies as trade stock. As to the best class of tea he is satisfied that he could hold his own under present conditions in the Fiji market. Mr. Barratt told us that he and his partner had had enough of Fijian labourers at present cost of them and unless liberal concessions were made quickly by the Government they would be compelled to close the place. Mr. Barratt, in reply to a question of Mr. Borron as to the suitability of coolies for the tea industry said, that if they had a larger capital to obtain a special class of labour mainly composed of women, their husbands and children, with a large percentage of the latter for picking tea, so that they might bring their area up to about 400 to 500 acres it would pay over 15 per cent interest on capital.

There is an abundance of land at Wainunu, thousands of acres unoccupied by natives heavily timbered and watered, with a luxurious vegetation different to any other part of Fiji and as fine as any in the world. The Estates under discussion have over 400 acres and plenty of adjoining land which they could attach at a low cost. Any altitude may be got and all sorts of tea manufactured. Large cutters come up the river to within a few yards of the factory and load for Levuka and Suva. The factory has two tea rollers, green sorter cutter, sorter and graders of the latest patterns, a large

first-class sirocco, and splendid fittings recently erected (for labour saving purposes) to work the green leaf. The quarters for manager, overseers and labourers are excellent, and much taste has been displayed in arranging the homestead and grounds. A stream of water has been tapped in the hills and brought down in iron pipes to drive a powerful Pelton wheel capable of developing eight horse-power which drives all, and could drive more, machinery.

The closing of this, the last of the tea estates aiming for an export trade, would be a very serious calamity and might extinguish all means of advertising or bringing under notice a product which would utilize large areas of land fit for no other purpose and employing labour unsuited to sugar cane cultivation.

W. J. EWINS.

—*Fiji Times*, Sept. 11.

ANOTHER PLANT FOR FIBRE:

"CALOTROPIS GIGANTEA"—THE "WARA" OF THE SINHALESE.

It turns out that the mission of Mr. MacDonald to Bombay and Sindh has to do with testing the fibre-yielding property of *Calotropis procera*, a well-known plant growing wild over Sindh and the Punjab. In this connection, a correspondent of the *Indian Forester* for September (see below) pleads for the testing as well of the fibre of *Calotropis gigantea*, a common plant in Southern India and Ceylon. We shall therefore be much interested in the result of Mr. MacDonald's mission; for, the latter plant—the "Wara" of the Sinhalese and also well-known to the Tamils under three different names, see below—is a very common plant in our lowcountry as the following account from Dr. Trimen's "*Flora Zeylanica*," shows:—

C. gigantea, *Br. in Ait. Hort. Kew.*, ed. 2, ii. 78 (1811). *Wara* *Singhalese*; Manakkovi, Errukalai, Urkkovi, *Tamil*.

An erect shrub or small tree, reaching 10 ft., bark yellowish-white, furrowed, branches stout, cylindrical, more or less covered with a very fine, adpressed, cottony pubescence.

Waste ground and roadsides, &c., in the lowcountry; very common, and often gregarious, Fl. all the year; pale violet or nearly white within, greenish-white outside, column pale blue.

Throughout India, Malaya, S. China.

Has a slightly fetid odour when bruised. The whole plant is very full of milky juice, which is given as a remedy for leprosy. The bark of the root (which is an official drug in the Indian Pharmacopœia) is employed as an alterative tonic. A very good fine fibre is obtained from the stem and used for fishing lines. The long hairs on the seed form a beautiful silk-cotton, used for stuffing. Charcoal for gunpowder is made from the stems at Jaffna.

CALOTROPIS PROCERA AND GIGANTEA.

You will probably be interested to hear that a representative of a firm (Messrs. Boyle and Company, London) is on his way to Bombay for the purpose of undertaking experiments in extracting fibre from the *Calotropis procera*, a plant, the fibre of which has been known to be of excellent quality for the past twenty years or more.

A small consignment of the fibre was sent to Messrs. Boyle and Company to be reported on, who then asked that some of the stems of the plant might be forwarded to them to ascertain whether the machinery they possessed could treat and decorticate the fibre from the stems. There was no use of course in doing this as by the time the stems reached England, they would, it was known, be too dry, for the purpose of experiment. On being in-

formed accordingly Messrs. Boyle and Company resolved to send a representative to India with machinery to decorticate the fibre if possible on the spot, and their representative is now on his way to Bombay via Singapore. He will probably be here in the cold weather. The step Messrs. Boyle and Company are about to take is a bold one, and it clearly shows that they consider the fibre to be extremely valuable.

The next question is, is there a sufficient quantity of the fibre available in India at present from stems to enable an export trade on a large scale to be carried out, should the experiment turn out a success? *Calotropis procera* grows wild all over Sind, and it is also to be found, it is believed, in the Punjab in this state. *Calotropis gigantea*, the larger plant and one which yields the larger quantity of fibre in proportion to the cut stems, is common according to Brandis "in South and Central India, Burma and Bengal, Gorakpur, Oudh, and in great profusion in an isolated locality in the Siwalik tract near Kali Dungri below Naini Tal."

The fibres from both the *C. procera* and *C. gigantea* are equally good. As at present arranged Messrs. Boyle and Company's representative is to proceed to Sind to undertake experiments with *C. procera* there, and the Government of Bombay have very kindly issued instructions that all the local Revenue and Forest officers in Sind are to render Messrs. Boyle and Company's representative any aid that may be needed for the purpose of conducting experiments with the plant there. It may be, however, that there is a better field for such experiments in other parts of India. If so will Forest officers in India and Burma or any others, through the pages of this Magazine, kindly let it be known, and will they also state (1) whether *C. procera* or *C. gigantea* grows in their Districts, (2) if so to what extent and (3) whether there is waste land available for the cultivation of the plants?

Such information, if it be not too much trouble to obtain, will be extremely useful and valuable at the present time, and I shall be greatly obliged if some, at any rate, will condescend to come forward with it.

As *C. gigantea* yields a larger proportion of fibre to the cut stems than *C. procera* and as there may be an equally large quantity of the plant available as in Sind for immediate experiment, in some other district of India or Burma, it might be advisable after the completion of Messrs. Boyle and Company's experiments in Sind for their representative to go elsewhere.

An interesting monograph on *Calotropis gigantea* was written some years ago (1878) by Mr. Strettell, Deputy Conservator of Forests and he described it as being indigenous in Sind. He was in error here, for the plant which is to be found in that Province is *Calotropis procera*. Mr. Strettell in this paper shows how much more valuable the fibre of *C. gigantea* is than jute and how much easier the plant is of production. As regards its facility for producing and reproducing itself there can be but one opinion. I have seen it (*C. procera*) growing on the summit of rolling plains of sand away from the Indus and on fallow kharif land near this river. It coppices freely and in about 12 months the cut stems are again ready for the extraction of fibre.

My experiments in Sind were conducted, it ought to be mentioned, with the aid of Ranger Dulpatri who obtained the cut stems for me and the fibre was stripped from them in my presence.

In 1891 Messrs. Ide and Christie, Brokers, of 7 Mark Lane, London, valued the fibre @ £15 to £23 per ton. In Mr. Strettell's time the market value of the fibre was £30 to £40 per ton.

I imagine its present market value must be rather in accordance with Mr. Strettell's figure or perhaps higher judging by the action of Messrs. Boyle and Company who are sending out a representative at their own cost and armed with machinery for conducting experiments on the spot. They were not invited to come out here, but merely asked to report on the quality of the fibre and its market value. Their enterprise is certainly very commendable.

15th September, 1897.
—Indian Forester.

G. M. R.

COCONUT CULTIVATION AND MANUFACTURE OF THE OIL IN SOUTHERN INDIA AND CEYLON :

WHY SHOULD COCHIN OIL SELL 36 PER CENT BETTER THAN CEYLON ?

HOW TO IMPROVE THE CEYLON COPRA.

A most practical question, and one that has been far too long neglected, is raised in the enquiry with which we head our remarks, Can there be any permanent unchangeable reason why "Cochin" coconut oil should fetch, on an average, 36 per cent. more value in the London market than the coconut oil from Ceylon? Cochin is three degrees farther from the equator than Colombo; but in most respects must have a climate and soil very similar to that of our West Coast, save that its dry season is said to be longer. Applying to a Colombo friend with prolonged experience for an explanation, we have been favoured with the following interesting remarks:—

"The superiority of Cochin coconut oil over Ceylon oil is due to the superior whiteness and quality generally of the Cochin copra as compared with Ceylon copra. Although the S.-W. monsoon rains from end May to August are very heavy in the Cochin State, there is a larger number of dry months than in Ceylon and it is in these dry months, that the coconut kernels are dried in the sun only, which gives a whiter and better copra than the average of Ceylon, and as Cochin oil is made from this whiter copra, this accounts for its superiority. It is not supposed that the Cochin coconuts are practically better than Ceylon nuts, but that the superiority of the Cochin oil may be attributed solely to the better climate, and to the superiority of the preparation of the copra from which the oil is made. Cochin oil is believed to contain a larger proportion of stearine than Ceylon oil, and hence its special suitability for the manufacture of fine candles such as those made by Price's Patent Candle Company, which are so well and favourably known to the public."

We give next an interesting communication, —which, in reality, prompted our enquiry—that reached us by a recent mail from a very old Colombo merchant long retired from the island; we have filled in the figures of rainfall and temperature for our West Coast as desired by him. He writes as follows:—

"Has the question ever been raised and discussed wherefore there should exist such a material difference in the value in Europe between Ceylon coconut oil and the oil shipped from the Western Coast of India? It is quite worth discussion. Though a difference in climate may account for part of the difference in value, there are methods in the cultivation of the nut and the preparation of copra which, if attended to in Ceylon, should increase the production of nuts and improve their quality and, therefore, the value of the oil. The climate of the West Coast of India differs greatly from that of Ceylon. The southwest monsoon beginning about the middle of May is generally one continuous downpour until about the first week in August; during which period mostly 100 inches of rain are measured, some 20 more inches falling during other parts of the year. In Ceylon the average fall in the low-

Prices in London (6th October) Ceylon oil £22; Cochin oil £29 10s at £30.

country ranges from 90 inches at Galle, 88 at Colombo, 68 at Negombo to 54 at Chilaw. The temperature in Cochin ranges from 80° to 90° Fahr.; whilst on the sea coast in Ceylon the thermometer averages only about 79 at Galle and Puttalam and 80 degrees at Colombo. In both particulars there is therefore a considerable excess over Ceylon.

"The cultivation of the coconut palm for nut-production and copra-making, so far as these terms are applicable to Ceylon, is much influenced by the character of the natives of the two countries. The Sinhalese are not a painstaking people; the natives of South India are more intelligent and will take very much more trouble in all the work of their hands. No doubt the natives of both countries recognise the good old proverb, that 'the coconut tree likes to hear the people talk,' and the good effect of burning the dry fallen leaves underneath them to destroy injurious insects. The Indian 'prunes' his trees: that is, he cuts away the old stalks which have borne nuts. For cultivation a very simple process is practised, viz., breaking up the soil about the roots generally into little heaps, into which are brought the ashes of burnt leaves, at the time when the immediate advent of the monsoon is apprehended. Both these simple processes increase the yield of nuts, so that in ordinary years there is a bunch of ripe fruit, often of 12 nuts to be gathered every month.

"The making of copra is a careful operation in India; and far otherwise in Ceylon. The nuts when opened are not placed on the bare ground in the sun or exposed to a fire; but clean mats are put down to which the women attend, taking them in at night or covering them over on the approach of rain. The pressing of the oil by the checku is the same in both countries; but even in this part of the process the Indian is the superior in cleanly methods.

"These few hints are given for what they are worth. It is not supposed our native friends in Ceylon will change their methods; but European proprietors and superintendents of coconut plantations by accepting these recommendations may increase the produce of their trees and improve the quality and value of their oil. Sometimes a red tint is observable in the oil. This arises from too long delay between the gathering from the tree and the conversion of the kernel into copra by exposure to the sun; especially when the nuts in their husks are piled in heaps in the open air, germination having commenced within the shell. These should be carefully avoided, germinating nuts being discarded. What is desired is a clear colourless oil when finally pumped into the casks for shipment, to procure a white solid sample when offered for sale in London or at the Continental Ports."

We now return to the practical question with which we opened. Surely, we may say we have as good coconut palms in Ceylon as on the Cochin coast; as good soil and a climate equally favourable at least in the districts North of Colombo (and in Batticaloa and Jaffna?); and if this be granted what is to hinder equally good copra being prepared here? It seems to us that the explanation must be found in the greater care exercised by the natives of Cochin in their handling and drying of the copra—a fact that is testified to by both our mercantile

correspondents, and that it should be quite possible, say in the Maravila and Chilaw districts, if not in the Negombo district—to prepare with a little extra care, copra equal to that of Cochin.

For instance, not only can Negombo, Maravila and Chilaw (including Rajakadalawa) boast of most luxuriant palms growing in fine soil; but even Cochin can scarcely show a much larger number of dry sunny days during which copra might be prepared. We find that the meteorological record for the several centres of coconut cultivation in Ceylon runs as follows:—

Name of Station	Average annual total:			Side of Ceylon.
	Rain-fall	Rainy days	Dry days	
Colombo	88.52	171	194	West
Heneratgodia	93.84	148	217	West-inland
Kalutara	86.03	151	214	South-West
Galle	91.47	205	159	South
Matara	68.26	49	266	South
Negombo	67.11	98	267	West
Chilaw (Horakelle)	65.45	92	273	North-West
„ (Rajakadalawa)	51.3	106	259	North-West
Puttalam	46.36	78	287	North-West
Kalawewa	50.14	76	289	North-Central
Kurunegata	84.12	168	197	Central (low-country)
Jaffna	47.68	72	293	North
Batticaloa	54.85	101	264	East

From the above we would specially select the Negombo, Chilaw, Kurunegala, Jaffna and Batticaloa districts and ask, for what reason—if sufficient manual care be taken—as good and attractive copra cannot be prepared from the coconuts in each of these as in Cochin? We have heard, indeed, of plantation copra from Batticaloa being pronounced very superior to ordinary Ceylon. Is this an established fact? If there is no other remedy, would it not pay on some of our plantations to import some natives of Cochin accustomed to manipulate the coconut kernels for copra in that State?

We await the opinions, or experiments of practical planters in the districts referred to, from whom we shall be glad to hear on the subject; for surely, if increased care in preparation increase the price of a great part of Ceylon oil even ten or twenty, much more by thirty-six per cent., there is ample reward awaiting the experiment. One point may be raised as to the greater proportion of stearine in Cochin coconut oil; if this be due to soil, we should have to get samples from Cochin to analyse and compare with our Ceylon coconut soils*; but we cannot believe there can be much difference in this respect between the best of our West Coast and the Coast of Cochin. The difference is most likely to arise from the more careful cultivation of the palm, the plucking of ripe nuts only, and the watchful manipulation, as already described, of the kernels to secure the best copra. All this should be within the reach of coconut estate proprietors in Ceylon, at least in some of the districts we have selected as most allied to Cochin in climate and soil.

CEYLON VS. COCHIN COPRA.

On the subject of the above article we have drawn up the following questions and circulated them among authorities in Colombo who have not already given us their opinions:—

The first set of answers to reach us, is from Messrs. Volkart Brothers, and this firm with

* We suppose there are European oil-preparing mills at Cochin as at Colombo?—Ed. T.A.

* There is a valuable chapter of analyses for "Coconuts" (soils, nuts, oil, &c.), in Cochran's "Ceylon Manual of Chemical Analyses."—Ed. T.A.

prolonged experience both here and in India, shew clearly that much more might be done with Ceylon copra :—

1. Yes ; Cochin copra is never smoked or kiln-dried, always sun-dried ; hence the oil, that is pressed out of it, becomes whiter.
2. Our opinion is that if the same method in preparing and drying copra as at Cochin, were practised in Ceylon,—Ceylon oil would equal Cochin oil or nearly so.
3. Certainly.
4. ———.
5. Jaffna and Batticaloa.
6. For merchants and mill owners it makes but little difference, whether ordinary or white oil is being shipped. It would certainly be to the interest of planters, to adopt Cochin methods and send people over to study these or employ Cochinese here.
7. We are the largest shippers of copra from Ceylon and employ Malabar people to superintend drying etc.
8. Calpentyn, Jaffna and Batticaloa supply the best copra ; Madampe the worst.
9. ———.

Per Pro. VOLKART BROTHERS,
A. BOHLMANN.

THE CALEDONIAN (CEYLON) TEA ESTATE LIMITED COMPANY

Is generally discussed in the home press. It is reconstructed and enlarged from the Company started by our old friend and veteran colonist, Mr. Alex. Ross—one of the best planters who ever came to Ceylon—and he along with Sir Alfred Dent and Mr. Wm. Gow constitute the Directors of the new Company, while his son Mr. J. S. Ross is Manager out here, the Secretary being Mr. H. F. Stanley and offices at 11, Old Broad Street. The capital is £200,000 with a first issue of £110,000 in Preference, Ordinary and Debentures. Here is the criticisms of the *Daily Chronicle* on this issue :—

Only the profits for one year are given, which, from the three most advanced estates, amounted to nearly £7,000. There is no valuation given of the properties to be taken over, but taking the price of the uncultivated land at £10 per acre, and the land under cocoa at £30 per acre, the price of the land under tea, including the factories, buildings, and machinery, is under £55 per acre. The present issue will leave £7,000 available for working capital, and the remainder of the capital is held in reserve for the future extension and development of the estates. The future of this class of company is largely a question of management. Tea companies are, as a rule, only applied for by those who have a certain amount of local knowledge and experience of the trade, who can be trusted to look after themselves.

The prospectus has a good deal of interest to Ceylon readers :—

This Company is formed to take over as going concerns the properties of the Caledonian (Ceylon) Tea Plantations, Limited, consisting of the Venture Estate, situate in the Bogawantalawa District, and the Selegama Estate, situate in the Matala District, also to acquire as going concerns the Kahawatte and Waweena Estates, both situate in the Matala District, and the Lawrence Estate, adjoining the Venture property in Bogawantalawa, and to acquire other estates in Ceylon and elsewhere as favorable opportunities occur.

The acreage of the estates now acquired is as follows :—

	In full bearing.	Planted and in partial bearing.	Timber clearing	Forest.	Cocoa.	Total.
Venture	399	0	5	12	—	407
Lawrence	450	50	—	65	—	565
			Forest and Chena.			
Selegama	200	300	—	530	—	1030
Waweena	20	220	—	46	—	286
Kahawatte	—	—	—	236	160	396
Acres	1060	570	5	889	160	2684

All the above land is freehold, except about 140 acres of uncultivated land on the Kahawatte Estate, which is leasehold. The greater part of the land planted with tea is situated at a high altitude in Bogawantalawa, one of the finest tea-producing districts in Ceylon, and the remainder is situated in Matala, a district which has lately come into great favor for tea planting.

The net profits of the Venture and Selegama Estates for the season ending 30th June, 1897, and of the Lawrence Estate for the year 1896, with a total crop of 465,000 lb. of tea from 1,060 acres, were nearly £7,000. None of the young tea on the above-mentioned 570 acres was then in bearing.

The yield from the estates now acquired for the present season (1st July, 1897, to 30th June, 1898) is estimated by Mr. J. Stanley M. Ross, the manager of the properties, at 535,000 lb. made tea. Taking the rate of exchange at ls. 4d., and assuming that the tea will realise an average equal to that of last year (which may reasonably be expected, as the bulk of tea is produced at a high altitude), the profits should be approximately £7,500, which amount, after providing for the debenture interest and preference dividends, as well as London expenses, should leave a surplus sufficient to pay a dividend of about 8 per cent. on the present issue of ordinary shares. The profit should go on increasing as the 570 acres of young tea mature and come into fuller bearing, and there is still a large reserve of land available for planting.

A considerable portion of the Kahawatte Estate is believed to be suitable for the cultivation of coconuts, which will be undertaken should it be thought advisable to plant up the available land with this product.

The estates are in a high state of cultivation, and are well equipped with factories, bungalows, coolie lines, and sufficient machinery for all present requirements. The rainfall is ample, and the facilities of transport are excellent as the estates are all connected with the railway by Government or other roads.

The prices to be paid by the Company for the purchase of the estates and properties have been fixed by the several vendors at sums amounting together to £103,000, payable as to £11,000 in preference shares, as to £11,000 in ordinary shares, as to £13,000 in debentures, and as to the remaining £68,000 in cash. Taking the price of the uncultivated land at £10 per acre, and the land under cocoa at £30 per acre, the price of the land under tea, including the factories, buildings, and machinery, is under £55 per acre. The vendors will discharge all outgoings and liabilities belonging to seasons 1896-7, in respect of the estates up to the 1st July 1897, from which date the Company will be entitled to the profits ; but the Company will repay the vendors all advances made by them before that date, on account of the present season, and will take over all outstanding coast advances, and all stores purchased by the vendors for future use and in hand on the 1st July 1897, at cost price.

The present issue will leave an ample surplus for working capital, while the unissued capital and debentures will provide funds for opening out more land and purchasing additional properties as required.

MR. CHRISTISON ON CEYLON TEA ESTATES.

We call special attention to the cautious but valuable deliverance of our visitor, Mr. Christison—experienced Darjeeling planter as he is—as the result of his observations during the present trip in our tea districts. His remarks deserve careful attention. On the whole we consider they will tell in favour of Ceylon plantations; for the “possible dangers” have often been thought about locally, and the far more plentiful planting of tree belts and boundaries has had reference to blight as much as to fuel supplies. But more still should be done in this way.

Then as regards “want of rest” to the tea tree in Ceylon, we go on our oldest fields and the annual favourable report still from Loole Condura estate after 28 years’ experience. The same may be said of Mariawatte with its specially heavy cropping and yet which Mr. Christison no doubt found as flourishing in 1897 as in 1883.

Mr. Christison is quite right about tea at high elevations in Ceylon. So far back as 1864, we were taken by a Haputale planter—long since dead—who had had six months in Assam before coming to Ceylon, to see the forest-clad valleys behind Baker’s Farm, as, in his opinion specially fit for the opening of Tea Gardens! But no one would authorise tea-planting in Ceylon for many years after that and even in 1878, first-class tea seed was unsaleable in Colombo and was talked of by a bigotted coffee planter as “troublesome stuff” to be put in anywhere! Mr. Christison must know how much more deeply rooted tea is than its surface-feeding predecessor, coffee.

MR. CHRISTISON OF DARJEELING IN CEYLON.

THE ADVANTAGES AND DISADVANTAGES OF CEYLON AS A TEA-GROWING COUNTRY.

Mr. Christison, late of Darjeeling, has returned from his visit upcountry to the tea districts, his excursions having been to the following estates and districts:—Colombo to Kandy, visiting Hantana, New Peradeniya, Udagama, Galaha, Haragama, and many other places; thence to Gampola (which he visited in 1883); and on to Adam’s Peak Hotel. He saw Wanarajah, Kintyre, Laxapane, Avoca, Bogawantalawa, Talawakelle, Diyagama, Agradatana, Great Western, Abbotsford, Nuwara Eliya, Naseby, Scrubs, Udapusellawa; and, on his return to Colombo, one or two lowcountry estates near Alutgama. Besides travelling by train he posted 196 miles, and in addition walked considerable distances. Our representative interviewed Mr. Christison a few days ago at the Grand Oriental Hotel, and the following is that gentleman’s own account of the trip, though it is only fair to say that he would have preferred waiting before he gave his views so that he might have given fuller consideration to some of the points he advanced:—

GENERAL IMPRESSIONS.

I am (said Mr. Christison) very sorry my tour in Ceylon has been such a hurried one, and I should very much like to have had three times the time at my disposal. I have, however, seen a great deal in the time and I think have arrived at fair conclusions if allowance is made for the shortness of my visits. Before I started I was told by Mr. John Ferguson I could see a great deal of

tea from the train. I have tried to see it by railway from Alutgama to Nannoya and back and in going twice over these journeys have looked well around me. I have posted 196 miles, and in many cases I have retraced my steps by other routes and gained other opportunities for observation. I have in addition walked on the gardens themselves, but not so much as I would have done had I been a younger man, and further I have walked from time to time considerably amongst the tea along the side of the roads. I have been connected with land all my life and with tea and tropical and more especially hill cultivation for thirty-five years. I am still diffident in expressing my views, but I must say I felt immensely gratified by the hospitality shown me on all occasions, and the unflinching readiness to impart information on the part of all whom I have met wherever I have been.

FULFILMENT OF A FORECAST.

The longer I live and the more experience I gain the more cautious do I become in expressing dogmatic opinion on many points connected with tea. Instead, therefore, of stating my present impressions, gathered from my rapid tour, I would much prefer merely to recall attention to two prophecies I ventured 14½ years ago.

In 1883 when in Ceylon I expressed a decided opinion to the late Mr. A. M. Ferguson—I was standing at the time at a high elevation. I then said that my experience in Darjeeling in 1863 led me to consider from 3,000 to 4,000ft. the best elevation for tea. In 1883 I thought the best elevation in Darjeeling was 4,000ft. to 5,000ft. I then said to Mr. Ferguson that I was confidently of opinion there would be no fault to find with tea at 6,000ft. or over in Ceylon, considering the difference in latitude when compared with Darjeeling. “If,” I then said, “you have the soil there, I believe it would be found a most advantageous elevation for tea, and that it will be the best for flavour and in other respects.” That was commented on at the time, in May, 1883, I have no hesitation in repeating that. I remember in October or November of that year I was at a meeting of the Lebong Company; there was then considerable attention directed to Ceylon which was then beginning to attract notice as a tea-growing country, and my shareholders expressed considerable anxiety as to Ceylon becoming a formidable opponent to Darjeeling to its disadvantage. They asked my opinion and on the spur of the moment I gave it and the reply was

ADVERSELY CRITICISED IN CEYLON.

I then replied that from the impression I had gathered the soil was not sufficiently good and I had seen some instances of large estates between Nuwara Eliya and Kandy, changed from coffee to tea, which would not, I thought, be remarkably successful. Considering everything, I added Darjeeling had not much to fear from Ceylon although they had been getting fancy prices (30s a pound) for their tea, and though their average was higher than ours. Still, I then said, when Ceylon got into full bearing and full crops their teas would not be found equal to the best Darjeeling. Tea I tasted in Ceylon (though not a tea-taster) was not in flavour equal to teas I had seen from Darjeeling, and that I believed Ceylon teas would ultimately find their level nearer that of Cachar.

THE PRESENT DAY.

Those two prophecies (said Mr. Christison) I have no hesitation in now repeating. I have however been through many estates and I have a much

higher opinion of your soil than I had then. I believe there are more than one or two districts I have seen which possess great natural advantages in every way, and are capable of doing anything that is attainable in tea. I have seen a great deal of the island and I must say I have seen nothing I consider poor except some small scraps going up to Kandy. I have seen no "poor tea," but a great deal I consider very fine.

A HEALTHY PLANT.

I have been impressed with the healthiness and robustness of the plant. I may say I have seen surprising little signs of sickness or distress in any part, and hardly what I consider a trace of blight. I have also seen some very fine factories, probably the largest in existence at the present day, admirably arranged and most efficiently equipped. I hardly saw a weed within the whole area of cultivation. I was very much struck with that, for it is such a contrast with our hill district of Darjeeling. I saw none,—not even in the channels, or the banks of the streams, or in fact in any direction. Another thing that struck me was that I never saw throughout the whole of my excursions any attempt at terracing.

FURTHER TEA INVESTIGATION.

I propose to visit ten more tea districts in India and elsewhere. It is twenty-one years since I was in Assam: it is seventeen since I visited Cachar and Sylhet: and nineteen have elapsed since I was in Dehra Dun. It is four years-and-a-half since I was in Darjeeling, but I have been in constant communication with them there, so that is the only country of which I have up-to-date information, and comparing Ceylon with that I consider you have the following

ADVANTAGES.

- 1.—Climate.
- 2.—The slopes are more gentle, lending themselves better to terracing, manuring and surface draining.
- 3.—The estates are less costly in the preparation of the land for planting and in after cultivation.
- 4.—In regard to transit you have splendid roads with easy gradients. Even in the gardens themselves you have the advantage over us for everything is carried on men's backs in Darjeeling.
- 5.—In regard to water-power you are most advantageously situated, the water being more easily brought to the side of your factories than is the case with us.
- 6.—The soil is even (though I consider nothing I have seen any where in Ceylon equals our best Darjeeling soil) and the land less broken up. There are fewer uncultivable portions. The gardens are much more compact.
- 7.—Looking at the physique and health of Europeans of long residence, I am convinced that even with the fine climate of Darjeeling you have an advantage.
- 8.—Through all the hill districts, so far as I have seen, the rivers are gentle in their flow; to some extent they are navigable with slight artificial aid. They are such a contrast to the mountain torrents of Darjeeling.

POSSIBLE DANGERS.

Nature (continued Mr. Christison) has been so lavish and so liberal to you that I am afraid you do not realise the importance of some sources of danger. May I diffidently suggest the following:—

- 1.—I have spoken as to the healthiness of the plant I have seen; but I believe in no instances in any former experience in any crop

where there has been such a surface covered, has there been exemption from blight. This ought to be thought about. I sincerely hope you will escape, but you will be exceptionally fortunate if you do. Wherever there is a large area of cultivation, no matter what plant, in any country and in any climate, there comes in time blight.

2.—The want of rest for the plant is another source of danger. You are always plucking or pruning. Pruning is not a rest, but a surgical operation more trying than plucking. I look upon it as a more severe process for the plant than plucking.

3.—I have seen some indications of waste of soil by wash and this requires to be seriously thought about—the effects of wash year by year, the carrying away of the constituent properties of the soil by rain. Yours is a light friable soil and in spite of your admirable and complete system of drainage this requires grave attention.

4.—We do not know the life of the tea plant yet. When tea is reduced to a science, the deterioration of the plant will be understood and must be reckoned with. Wherever the plant comes into full bearing, you ought to write off a sum for annual deterioration of the plant in the same way that you write off for deterioration of buildings, and other property.

5.—In many districts the want of firewood fuel will become very pressing, and, though I give you credit for much planting along roadsides and also separate plantations, further steps in this direction might be carried out with advantage in the shape of separate forest plantations.

For thirty years (said Mr. Christison in conclusion) I have been fighting against nature in a climate where we had practically five months without rain and I am consequently alive to some of these points I have mentioned. One thing I should like to do—to go back to the beginning of coffee and see what your land was like then. It is not what it was, but it is capable of very much now with the climate you have got. Too much attention cannot be paid to preserving and fertilising the soil, but especially to prevent any more of it being carried down your rivers. I have expressed myself hurriedly, and with many imperfections, but what I have said I have put forward with the most kindly feelings towards all associated with the tea industry in Ceylon.

FIBRES GALORE.

A PRACTICAL agriculturist writes to us from an outstation regarding Ramie or Rhea:—

"As regards the Rhea fibre industry, which has recently been the subject of discussion in the local press and is now causing anxiety in the minds of some planters, one can easily understand there can be such a thing as having an 'eye to No. 1.' Mr. MacDonald's figures for yield of crop were evidently based on a character of soil not very general in Ceylon. And yet Mr. MacDonald himself does not appear to have granted this, for, when talking as to soil for the Rhea plant, he strongly advocated planting thickly amongst coconut trees, 'the closer the plants and the more complete the shade from the coconut trees, the better the canes for fibre.' This should prove something worth knowing to owners of large coconut plantations."

We cannot believe that crops of raminé would not interfere with the crops on coconut palms; for, the roots of the latter spread out a great deal from the parent tree.

Regarding *Calotropis Gigantea* or Wara, a planter writes from the Gampola district:—

"I am very much interested in all about Fibres, and, on reading in *Observer* yesterday about the 'Calotropis Gigantea, the Wara,' I sent out and got some of it, and send you by same post a packet containing the leaf and flower, also a small sample of the fibre. The latter seems to be very fine, and, if it doesn't set the ships on fire, like the New Zealand flax did, we should be able to ship it in large quantities, if machinery to clean it properly, and labor for growing and harvesting it, can be got. If it could be cultivated on road-sides and all vacancies in the tea supplied with it, I fancy the coolies would be glad to cut and bark it for the sake of the sticks on lowcountry estates, where fuel is so scarce. It would be a valuable requisite for Ramsamy as well as an additional revenue for the estates. You might kindly show it to some of your friends, and I will be glad to know if I have hit on the right plant. It seems to answer to Dr. Trimen's description of it."

We have not the slightest doubt that our friend is right; we recognise the flower, and an intelligent Sinhalese in our office pronounces it to be the "Wara." We must now await Mr. Macdonald's report on the allied fibre at Bombay; but meantime our friend cannot do wrong in going on with its cultivation, and as he says, on lowcountry estates, it ought to be very useful.

THE AMSTERDAM CINCHONA-AUCTIONS.

The cinchona-auctions to be held at Amsterdam on November 4th will consist of 5,691 hales and 437 cases. The stock in first hand, including the above quantity, now consists of 2,049 packages Government and 5,778 private bark. The market is very firm.—*Chemist and Druggist*, Oct. 16.

THE ADULTERATION OF COCOA.

At the Isle of Wight Petty Sessions last week, Edward Henry Guess, grocer, of Shanklin, was summoned for violating the Food and Drugs Act. Divisional-Sergeant King, said that on August 24, he visited defendant's premises at High-street, Shanklin, and purchased three-quarters of a pound of loose cocoa, he was served by a lad in the shop. The analyst's certificate showed that it contained 16 per cent. only of cocoa, with 24 per cent of sugar, and 42 per cent. of arrowroot. Mr. Drew for the defendant submitted that he had no case to answer as the buyer was not prejudiced, being served with loose cocoa, and was told by defendant that it was not pure.—The Chairman: There is 84 per cent. of adulteration, there is a case to go on with.—Mr. Drew said that it was known that pure cocoa could only be had at 3s. 6d. per pound. What was sold as loose cocoa was a wholesome mixture of cocoa, arrowroot, and sugar.—The Chairman said it was a bad case of adulteration, and fined the defendant £4 and 19s. 6d. costs, or in default a month's imprisonment.

Arthur Nobbs, grocer's assistant to Messrs. Perry and Co., of Ventnor, was similarly summoned.—The analyst's certificate in this case showed that there was 8 per cent. of cocoa 68 per cent. of sugar, and 24 per cent. of arrowroot.—Mr. Drew who defended, repeated his defence in the case previously mentioned, and urged that the mixture was not sold as pure cocoa. He asked that a nominal fine should be inflicted.—The Chairman said that this case was rather

worse than the last, as the purchase contained only 8 per cent. of cocoa. Defendant would be fined £4 and 19s. 6d. costs. The Court thought that the defendant's employer should pay the fine, as the master was really the responsible person.—Mr. Drew said the master was away from home at the time.—*Grocers' Journal*, Oct. 9.

THE NEW COFFEE CROP, B.C. AFRICA.

The present crop is estimated at 450 tons, which we believe is a low estimate. The quality, so far as we can gather, is on the whole excellent, so that in spite of the heavy Brazil crops good prices should be obtained. As was to be expected, the transport difficulty is again acute and many are the signs for the much talked of railway. Even on the river the A.L.C. has as much as it can do to keep its stores clear. In such circumstances we think they would consult the interests of the planters if they were to pass on some of the crop to the other companies, as it is essential to get the coffee out of the country as soon as possible. Mr. Morkel's carts are being kept busy and no doubt he sees that he could add to their number with advantage. Now that our roads are being so vastly improved, there is no reason why the present transport congestion should not be greatly relieved by ox waggons. Judging by the fast rate of progress of the railway scheme since its inception, we will have to depend on human carriage and ox-waggons for some years to come. The transport difficulty is, however, a healthy sign from one point of view, as it shows we have something to export. Let it press heavier and heavier every year and the railway is sure to come. It is too soon to prophesy as to next year's crop until the blossom showers have fallen, but so far as we have heard a healthy spike is showing up. Unfortunately at Mlanje some apprehension is felt on account of the locusts which have congregated in great numbers and it is feared may destroy the blossom as soon as it opens.—*Central African Planter*.

PLANTING NOIES.

RAMIE CULTIVATION.—The last words of Mr. J. M. Macdonald, before he leaves Ceylon this time, appear in our column in the form of a letter written in reply to the communication from Mr. Rosling. We shall follow with interest the further experiments that are now about to be made.

THE PRESENT PROSPECT OF TEA PLANTING IN FIJI.—This is the title of an article from the *Fiji Times* which we quote on page 379. It gives an account of the two principal estates in the islands, one being "Alpha" which was under the management of Mr. A. J. Stephen who is now in Ceylon, and the other, Wainunu. The labour supply seems to be one of the great difficulties there as well as here and liberal concessions by Government are stated to be urgently necessary if the industry is to be carried on.

CAMPHOR IN AUSTRALIA.—The camphor flora, it is well-known, grows very freely in these colonies. The increasing demand for camphor for use in explosives and in the manufacture of celluloid gives greater importance than ever to this commodity. The Japanese commenced to prepare it by distilling the leaves and branches of the trees instead of destroying only full-grown trees for the purpose. It seems to be worth while to ascertain if the shrub growing in the warmer climates will bear cutting sufficiently well to yield an adequate return of camphor when distilled.—*Chemist and Druggist*.

LOCUST PESTS.

The advantage of having an "honorary Entomologist," and one so well qualified for the post as Mr. E. E. Green, is well illustrated in the official correspondence, which we republish from the *Gazette*. The visitation of locusts referred to must have been identical with that in the Hapitigam Korale of the Western Province, to which we drew attention at the time. It is evident from what Mr. Green reminds us of Mr. Nietner's experience that different districts of Ceylon are liable to sudden visitations of locusts from time to time; but on so limited a scale that so far no extensive mischief has ever been done by them according to existing records. Nevertheless, to be forewarned is to be forearmed; and we trust Government will very urgently impress on all headmen the importance of collecting and destroying the locusts' eggs as described by Mr. Green. It is satisfactory to learn from him that, as regards coconut palms, the same precaution—tarring a circle round the trees—which prevents attacks from rats, will probably go far to prevent the locusts getting up the palms.

RAMIE CULTIVATION.

INTERVIEW WITH MR. J. M. MACDONALD OF THE STRAITS SETTLEMENTS.

Mr. J. M. MacDonald (of the firm of MacDonald, Boyle & Co. of London)—to whom prominent reference was made in a previous article on Ramie cultivation has been recently on a visit to Ceylon. He arrived here from Singapore and continued his journey *via* Bombay to London, leaving Colombo by the outgoing P. & O. steamer. He read our article, from many of the statements of which he at once intimated his dissent, and subsequently granted a representative of ours an interview at the Galle Face Hotel.

"You have," said Mr. MacDonald, "called me a sanguine man with regard to my figures, but as a matter of fact these figures are considerably understated. I do not say that they apply in the slightest degree to Ceylon. I know nothing of Ceylon or of its soil or capabilities. I was simply asked by Mr. Wickwar, of the Hill Club, to call here on my way home and see some of the planters, and give them my views with regard to Ramie, and explain what my machinery and process can do. I have, therefore, brought my machinery to demonstrate the whole process from beginning to end, and to show that from the moment of cutting the stem to the time of producing the white filasse only two hours and a half are occupied. Your article is not sufficiently specific to let me know the other points on which I am thought to be too sanguine, but if it is on the point of production it would be as well to give the following absolutely authentic information:—

PRODUCTION.

"In planting Ramie the cuttings should not be placed more than eighteen inches apart. I advocate only twelve inches. The closer (in reason) that cuttings are placed the better for two reasons: (1) that no weeding would be necessary after the plants are 3ft. high: (2) the stems grow perfectly straight without lateral branches which are very deleterious to the

fibre. The first cutting can be taken in three months, but to be on the safe side we will say six. Many experts have said that the first cutting from a plantation is useless, but here you see (showing a stick of Ramie) a three months' stick which has been produced from the estate of Mr. Thomas Gibson, the Secretary of the United Planters' Association at Klang (Selangor). You see that the stem is 5ft. high: it is at least half an inch in diameter, and with perfectly good and strong fibre, which you can find by taking hold of the fibre and pulling it. This stem is one of those produced from a cutting about six inches long, planted only three months before the stem was taken. The stool contained altogether fifty stems in vigorous growth, which no doubt in six weeks' time would have produced about a fifth of that number of mature stems. This plant is one of a number which Mr. Gibson had dug up and showed at a meeting of the United Planters' Association of the Federated Malay estates.

RAPIDITY OF PRODUCTION.

"With regard to the rapid production in the Straits Settlements, we have the evidence of Mr. Gibson's plantation, where, as I have already stated, in three months' time there is a crop of stems ready to cut and plentiful supply coming forward, a fifth of which in six weeks will be ready for harvesting. Now, instead of taking three months as the earliest cutting, we will assume that it will take six months to produce three stems and not six. It becomes necessary to consider how many stems can be produced to the acre and what the weight of those stems would be. During the course of the experiments at Kuala Lumpur in Selangor, carried on before a meeting of the United Planters' Association, a trial was made of a given number of stems taken haphazard from a heap lying there. It was found that the mean of fifteen stems, small and large shoots, weighed 4.8 ounces each, but for the purpose of our calculation we will say four ounces. Taking, therefore, cuttings as having been put in at 18 inches apart this would give eight to the square yard or 38,720 to the acre. Assuming that each plant only produces three stems each in three months and calculating these at 4 oz. each it is found that you can obtain thirteen tons per acre, and inasmuch as the stems renew themselves every six weeks this will give an aggregate of 78 tons of stems per acre per annum. Bear in mind that this calculation only assumes a production of half the quantity actually produced from Mr. Gibson's estate."

Mr. MacDonald here handed to our representative a printed report of the proceedings of the United Planters' Association, which fully bore out his statement.

HOW RAMIE IS DEALT WITH!

"We will notice now the reports of the 'experts,' when they speak of obtaining so many cuttings per annum, varying from two to four. The practice has hitherto been to mow down the whole plantation, hand over the stems to natives, when they are stripped by hand, and then the ribbons are dried and packed into bales and sent away. A native has to produce a certain quantity of ribbons per day. It is perfectly immaterial to him whether he strips mature or immature stems, and the result is that in one bale of ribbons we obtain in some cases as many as twelve classes of fibre. I need not point to you that this cropping system is a very objectionable one inasmuch as stems from six inches to two ft. high, which would be the large majority of the stems, are utterly de-

stroyed and wasted. I therefore advocate the daily cutting-system whereby only the mature stems are cut and so arranging your planting that this may be effected daily so that the coolie can go gradually through his two acres and on his return to the starting point he will find the immature stems be left have ripened and are ready for harvesting. By this means it is obvious, you more than treble the amount of your crop. I consider that each acre of land should produce three cwts. of stems per day. A coolie, therefore, from two acres of land, will have to cut six cwts. Taking the day at ten hours this means that he will have to cut about three stems a minute, and bale and deliver them every hour to the tram lines, when they would be picked up and delivered to the decorticators. Of course this is only possible in countries where the climate is equable throughout the year. The great advantage of this system ensures the quality of the fibre and is a guarantee to the manufacturer that the quality will always remain the same."

DOES RAMIE EXHAUST THE SOIL ?

"A great deal has been said with regard to Ramie as an exhauster of the soil. It has been thought, because it is possible to obtain more than eighty tons to the acre on good land under favourable conditions, that an enormous quantity of material must be taken away from the land, but it is entirely lost sight of that Ramie contains eighty per cent of water, so that after all there is not so much taken out of the soil as would be imagined, and if the system be adopted of returning leaves and the refuse from the decorticators, in the shape of ashes to the land, it follows that the fibre itself, (only from two and a half to three per cent of the crop) is actually taken from the soil."

THE AMERICAN EXPERIMENTS.

"Experiments were carried out by the American Board of Agriculture in California to test the exhausting nature of Ramie and an acre was placed under cultivation and the crops taken during four years. Nothing whatever in the shape of manure was applied to the land, not even the refuse from the stems, and it was found that the fourth year's crop was larger than the first. Of course this may be in consequence of the richness of the land, but at all events the fact remains."

RAMIE AT PERADENIYA.

"The only Ramie I have seen growing in Ceylon (added Mr. MacDonald) was in the Peradeniya gardens, where through the courtesy of Mr. Macmillan I had the opportunity of making a thorough inspection of the plants, which were growing most luxuriantly although they did not appear to have had very much care given to them. There were some very fine stems there, in fact I have never seen better, but none of them were ripe enough."

"Now," put in our reporter, "can you explain the divergence of opinion between you and the other experts, who have signed the official reports we have quoted?"

MESSRS. WRAY AND MATHIEU.

"I would rather not have made any remarks as to these gentlemen, if I could have avoided it (said Mr. MacDonald), but if you had printed the reports *in extenso* your readers would have gauged their value. I have the official printed reports before me now, and what do they amount to? Simply the admission on their part that they personally know nothing of the

subject on which they report, but have filled eight pages of closely printed matter with quotations from books showing the results obtained in countries differing in every respect from Perak, they then proceed to draw their deductions therefrom. Can anything be more mi-leading? Mr. Mathieu says of Mr. Wray's figures:—"Mr. Wray puts forward several figures which do not afford any basis of conclusion, owing to the fact that they are obtained from stages and conditions of growth not stated;" so much for Mr. Wray's report. Then Mr. Mathieu in his report says:—"The figures which I shall give hereunder are also from widely different countries, because, unfortunately, Ramie having been so far neglected no data can be drawn from Malaya." Surely this disposes of the whole question as to the value of these gentlemen's report. They are asked to report as to 'the prospects of Ramie cultivation in Perak,' and they say they know nothing about it, but they will consult their books and see what has been done elsewhere, entirely ignoring the fact of the different conditions under which the plant is grown. Had they been asked how many tons of Swedes can you grow to the acre in Perak? would they have reported, 'You can get 40 to 50 tons to the acre in England,'—because that is really what their report amounts to

"If these gentlemen would burn their books and study the question from a practical point of view, and cultivate the plant on a sufficiently large scale to enable them to obtain data and then visit all the likely countries where Ramie can be grown as I have during the last 4 years, they would become entitled to call themselves experts, but until then it would be better to give up writing reports upon a subject on which they have only second-hand information and to bear in mind (to quote a favourite expression of Mr. Mathieu which I have recently seen in one of his letters 'that a little knowledge is a dangerous thing,' a quotation I advise him to think over and lay to heart."

FUTURE SCHEMES.

"One word more and I have finished. I am sufficiently satisfied with the prospects of Ramie in Malaya to embark with my friends a considerable sum in starting the cultivation of Ramie to the extent of 1,200 acres the Muar district of Johore, a district which your expert, Mr. Mathieu has reported to be not suitable for the cultivation of Ramie, but in which I have proved his information to be incorrect, so that although my figures and ideas are magnificent according to Mr. Ferguson, he will at least give me credit for the pluck to carry them out, and I hope as soon as sufficient accommodation is available to see him, and any Ceylon Planter interested in the subject, when they may be assured of a hearty welcome and all the information which has resulted from the 'magnificent' undertaking, an undertaking in which I have secured the moral and financial support of His Highness the Sultan of Johore, who has taken the warmest interest in the future of Ramie."

The interview here ended. Mr. Macdonald added as our representative left that there is no fear of a market for the present, as one firm alone in Dundee had offered to enter into a contract to take 100 tons a month at £42 a ton, and inasmuch as the stuff can be grown, treated, baled, and imported into England with freights and all charges paid, including brokerage, at 1½d per lb. this would leave a very handsome margin of profit to the grower.

RAMIE CULTIVATION.

We are indebted to Mr. Rosling for the letter and information we publish on another page, and still more to Mr. MacDonald for the long and interesting interview granted to our representative. He is a little hard on Mr. Wray, who made no personal pretensions to experience, but performed the duty of compiler, as called on by his official superiors, conscientiously. As for Mr. Matthieu, his information was specially based on actual experiments made at Buitenzorg, Java. However, these are merely side issues. We shall be delighted to hear of the success of experiments made in the Straits, and still more, of course, to learn that a trial on a likely spot is to be made in Ceylon. Mr. MacDonald finds fault with the use of so wide a margin in crop as from 500 to 1,120 lb. per acre. But he is, we suppose, aware that this is a very common experience in the tropics; our coffee crops in Ceylon in old days used to run from 3 cwt. to 8, to 10 and even 15 cwt. per acre. Then there is our tea industry, very much to the point, because tea leaves, like ramie fibre, contain a large percentage of water; well, Mr. MacDonald will find that our tea crops vary from 300 lb. of made tea per acre to the maximum of 1,000 or 1,100 lb.—or putting the weight in leaf from 1,200 lb. of leaf to 4,400 lb. and that this dries down to one-fourth. Tea leaf losing three-fourths weight in moisture while drying, makes it somewhat analogous to Ramie; and yet the richest soil in Ceylon constantly manured cannot supply more than *two tons* of tea-leaf per acre per annum, the plucking going on for nine months out of the twelve.

We do not for a moment say that Ramie planted so closely as Mr. MacDonald mentions, is not going to give a great deal more in weight of crop than the leaves of the tea bush; though we take leave still to doubt whether 20, 13 or even 10 tons of yield of fibre per acre per annum will ever be gathered continuously for any number of years, over an appreciable area in Ceylon.

For a suitable spot for trial it is no use looking to our Northern, North-Central or Eastern regions with their long periods of drought. It is evident that the South-west portion of the island is best, and we would advise the Southern Province, an alluvial section by the side of one of the rivers where perhaps sugar cultivation was tried long ago, provided the land has been left fallow since—or we have no doubt there is virgin soil available in the vicinity. We are extremely sorry that there is no crop of Ramie available at this moment to give a full trial to the Decorticating Machine which Mr. MacDonald has so considerably made available. Better luck next time; and he may depend on our watching very closely all that is done at the Straits.

VANILLA IN SEYCHELLES.

Things here are very quite. The Vanilla crop this year is now being shipped home, the ss. "Baucoora" taking about £20,000 worth *via* Colombo. The prospects for 1898 in Vanilla are still very uncertain. We fear that the flowering will not be so heavy as last year. Prices still keep up, whole crops have changed hands at R16 per $\frac{1}{2}$ kilo and selected parcels of long beans have fetched up to R18. The high prices and good crop of last year have had the effect of greatly stimulating imports. The Customs receipts are about R10,000 higher than last year, other taxes have also yielded more.—*Zanzibar Gazette*, Sept. 29.

THE AMSTERDAM CINCHONA AUCTIONS.

Telegraphing at five on Thursday afternoon, our Amsterdam correspondent states: The most critical cinchona auction of the year is over, and has resulted in an advance of fully 45 per cent upon its immediate predecessor. The total quantity of bark offered was 4,287 packages, of which 3,905 were sold; the quantity of sulphate of quinine represented by the bark offered was 21,781 kilos, of which 19,571 kilos found buyers. The average unit realised today by manufacturers' bark was 6.27c per half kilo, equal to about 11-8th d. per lb., against 4.32c, equal to about 11-16th d. paid at the August auctions. The following figures represent the quantities of quinine sulphate secured by the principal buyers: American and English manufacturers 3,439 kilos; Anerbach 3,701 kilos; Brunswick 2,752 kilos; Mannheim and Amsterdam 5,391 kilos; Frankfurt-a-Maine and Stuttgart 1,633 kilos; various other buyers 2,835 kilos. The tone throughout the sales was exceedingly animated. Manufacturing barks realised from 18c to 58c, equal to 3 $\frac{1}{4}$ d to 10 $\frac{1}{4}$ d per lb., and druggist's from 16 $\frac{3}{4}$ c to 60c, equal to 1 $\frac{1}{4}$ d to 10 $\frac{1}{4}$ d per lb.—*Chemist and Druggist*, Oct. 2.

COFFEE PLANTING IN BRITISH CENTRAL AFRICA.

It is cheering to have practical and responsible planters reporting favourably of coffee prospects in Nyassaland after the many adverse reports recently current. The fact is, it requires one who can look back to what "pioneering" meant in Ceylon thirty to forty years ago, to do justice to the present stage in British Central Africa. Young planters trained in the "railway" and "district road" era in Ceylon—the era of district doctors, hospitals, padrès, bakers, butchers, general stores, almost of district hotels and all the conveniences of civilisation—are quite unfitted to judge of *pioneering*. Let them try living on rice "roties" for a number of months—as we found old Thomas Wood and his Assistants on Spring Valley doing in 1865, because there was no baker nearer than Kandy; let them become Assistants even now in Monaragala district, or to the South-east of Gongalla, or in the heart of Bambarabotnwa; and then they can speak of a little bit of pioneering experience and may exclaim by-and-bye,—

"If you had seen these roads before they were made,

You would have held up your hands and blessed General Wade!"

In the interesting letter which Mr. Israel, the responsible manager of a large group of coffee estates in British Central Africa, sends us—see our Correspondence column—he speaks of the transport of coffee to the coast costing £3 per ton. We can recall Uva coffee costing £6 per ton to bring it 170 miles to Colombo, or more than its cost for freight over 15,000 miles via the Cape to London; while the labour difficulties of the Uva pioneers and planters for many years were infinitely greater than any so far realized, judging by the experience of Mr. Israel and Mr. Henry Brown, in British Central Africa. Under these circumstances, we hail with pleasure the cheery optimistic utterances of our correspondent, and we hope his labours as also those of the Ceylon Nyassaland Coffee Company Manager and Assistants will be crowned with all the success they, or their proprietors and shareholders, can desire.

We also call attention to an article on Coffee Planting from the *British Central African News*, on page 390, in which a first list of the

coffee properties in British Central Africa is given. The total acreage planted, it will be observed, is very considerable, albeit most of the clearings are young. Some local authorities think shade will be needful for coffee in Nyassaland as it is in Mysore and Coorg.

COFFEE IN BRITISH CENTRAL AFRICA.

It has often been discussed within this Protectorate as to whether a coffee bush will continue to bear crops for a long period. It is worthy of notice that a patch of the oldest coffee in the country, on Messrs. Buchanan Brothers' Zomba plantation, which was planted 12 years ago, this year gave a crop of between three and four hundredweight to the acre of good coffee.—*B. C. Africa Gazette*, Aug. 1.

The following notes on coffee plantations in B. C. A. have been recently collected by us. As our readers will see, they are by no means exhaustive, but are meant to give outsiders in other planting countries, such as Ceylon, India, &c., some rough idea as to what is being done in coffee in B. C. A.

We have been freely supplied with information and statistics by all the planters we have applied to (except one). Should we have omitted to mention any plantation now in existence, it is through inadvertence.—*Ed. B. C. A. Gazette*.

NAMASI DISTRICT.—The agent of Mrs. A. L. Bruce at Namasi has now about 200 acres of coffee planted, and a clearing of 70 acres ready to plant out. From what is seen of this plantation from the main road, it appears to be in a thriving condition. Plants of two years' growth look particularly healthy. Mr. Owen Stroud has been in charge of this estate since Mr. Livingstone's departure on leave of absence, and the neat appearance of the estate shows what care is bestowed on it. There is a line of blue gum and Pride of India trees along the road, and another line of Mlanje cedars planted a little further back. With a good brick house, which is being erected this year, the plantation will be completed.

Mr. J. Boyd-Wallace has already planted 116 acres, and has about 100 acres cleared ready for planting next season. Mr. Wallace has laid out his estate with taste, and the roads passing through are lined with Pride of India trees. All the plants are only of one year's growth so that two years must elapse before a return is obtained.

Mr. Gordon Mitchell's estate is being managed by Mr. J. R. Greenshields. He has about 70 acres under coffee: 100 acres of this is only first year, 70 acres second year, and 25 acres third year. This latter portion of 25 acres was originally planted with second nursery plants, and though this is but the second year since planting, the crop, being really third year plants is coming on, and looks promising. Mr. Greenshield, has also planted blue gums and Pride of India trees along the avenues on this estate, and along the main road. These are sufficiently well grown to afford shade. There is one rather noticeable feature in his estate in regard to shade: some of his young coffee plants were planted in the shade of a large *figus*, near the Namiwawa river, and though the rest of the estate looks in a flourishing condition, the plants under the shade of the fig tree are sickly and delicate.

The following are the other Namasi planters with the approximate area under coffee:—Messrs. Robertson and Wren, 140 acres cleared and about 150 acres planted; Mr. K. Keiller, 100 acres planted; Mr. J. Cameron, about 30 acres planted, and Mr. P. Morkel, about 40 acres planted.

Another flourishing plantation along the Zomba Blantyre road is that of Mr. S. Israel. He has about 60 acres third year, 70 acres second year, and 80 acres first year: about 210 in all. He does not intend to plant any more this year, but this does not tell against the rate at which he intends to extend his estate, because he has decided to transplant from his first year nurseries into a second year nursery,

and this, while being much cheaper than actually putting in the seedlings where they are to remain in the fields, does not retard their growth; and next year, when these plants are finally set in the plantations, they are expected to be much stronger for the second transplanting, and a smaller proportion of blanks are obtained. The following is an extract from Mr. Israel's notes on coffee:—

"The first step, of course, is to choose the site of your estate. I selected mine on account of the healthy appearance of the forest trees and rich growth of grass. When the forest is cleared, pegs are put in where the pits are to be dug. This is called "pegging." After pegging comes the pitting, then draining. In my case, I prefer to drain immediately after pegging, because the drains can be made better then. Thorough drainage is necessary, as the open drains prevent wash, and admit air into the soil. Then the ashes of the burnt trees and grass are carefully mixed with earth and put in the pits where the coffee plants are to be set. It is not advisable to leave the ashes exposed as the rain may wash them away, or the winds blow them about. Putting in the plants is a simple matter, if well looked after. Pruning should be constantly kept up, and is even advisable in the second nursery. I have between 30 and 40 men continually pruning. After the plants are three years old, before bearing, I make pits between the rows, one pit between every four trees, and into these pits I throw all the weeds, rotten leaves, and decaying vegetable matter, as a substitute for manure. Then I cover up these pits, and when the substances decompose, a valuable manure is obtained. I also "thatch" my plantations in bearing, that is, cover the ground between the coffee trees with grass. After picking my crop I propose to manure the trees of one part of my plantation in the following way: dig a hole about 12 inches deep and about one foot distant round the stem in a half circle, fill this with cow dung, coffee-pulp and ashes, well mixed with soil. Another part of my plantation I intend manuring with sulphate of ammonia and phosphates, of which, for an experiment, I have purchased six ton.

I have now commenced to plant shade trees, and have big nurseries of different kinds of Australian trees for this purpose, I shall not be able to tell of two or three years what effect the shade trees will have. Coffee estates might be advantageously laid out in gardens of from 5 to 10 acres each. When these are numbered and recorded, it is easy to make reference to certain plots, and to know what has been spent on them, when weeded, what is produced and the working by task work is easier. In this manner my estate is laid out and worked. The following improvements will become necessary for a systematically worked plantation. Large cattle stalls (built near the coffee gardens so as to save carriage of manure), brick houses, for collecting ashes and manure, and good brick houses for the native labourers (to keep them in good health), good stores for drying coffee, for grain, and for general merchandise. Well laid out vats add to the value of a plantation. I have never a scarcity of labour. Labourers are constantly applying for work, and even in the wet season I am always well off. The fact of giving them good houses, giving them the option of food or merchandise to buy food with, weekly supplies of salt, and medicine when anyone is ailing, adds to a certain repute amongst natives. I notice that every tribe has its peculiarities and special fitness for certain kinds of work:—The Ajawa for skilled labour, such as sawing, pruning, brick-laying, carpentering; the Machuga, a section of Ajawa, are a strong set of men, and well suited for building, cutting trees and similar work, where strong muscles are required. The Angoni cannot be beaten for pit-making or careful weeding, and the Atonga, a strong and active race, can be made useful for all-round work. The Anguru are not well suited for garden work, but are excellent for tenga-tenga work—carrying loads up to 75 pounds.

If, however, you happen to pity one of these men and pay him something extra for carrying a heavy load, he is never satisfied, whereas, if you take no notice, he makes no complaint whatever."

Mr. Israel has now been in the country three years and says he has had practically no illness. He believes "a really active life" and moderate living to be the secret of health in British Central Africa.

Mr. Israel's crop just picked is close on twenty (20) tons of parchment (from 50 acres).

Around Blantyre, Mr. T. M. Hastings has an approximate area of 300 acres under coffee; Buchanan Brothers at Chiradzulu, 80; the late Mr. Horace Waller at Nagafui, 50 acres; Buchanan Brothers at Lunzu, 200; Mr. Killer, Matope, 60 acres; Kuntaja, 75; Blantyre Mission, 10; Sharrer & Co., a small plot at Blantyre of say, 20 acres; Malotta, 20; Pettitt Brothers, on their various plantations, more than 500 acres; Lloyd, 30; Lamagna, 200; Hunter, 100; McLagan, 100; Jonathan Duncan, 100; J. Lindsay, 100; African Lakes Co., Mandala, 10 acres; Bismarck, 10; and David Livingstone, 10.—*British Central Africa Gazette*, Aug. 15.

BRAZIL COFFEE NOTES.

There have recently been fires, supposed to have been caused by incendiaries, on several coffee plantations in the vicinity of S. Carlos do Pinhal, Ribeirao Bonito and Araraquara. The losses reported are as follows:—Bento de Abru Vidal \$20,000; Borneza de Dourados, \$30,000; Capt. Aurelio Civatti, \$200,000. In the fire on Capt. Civatti's plantation 5,500 arrobas of coffee were destroyed. The merchants who have been discussing the depression in the coffee market held their seventh and final meeting on Saturday. Before adjourning they adopted resolutions in which among the means re-commended are the following:—Co-operative banking societies; reduction in the export duties; reduction in freight rates; responsibility of railway companies for losses caused by them or their employes; more stringent and efficient measures for punishing and repressing the theft of agricultural labor laws; measures for inducing immigrants to come to Brazil and to remain in the country; agricultural instruction of the necessary measures for the execution of the Torrens law; measures for promoting the increased consumption of coffee in foreign countries; negotiations for obtaining a reduction in the import duties collected in certain countries on coffee; cultivation of food products on a larger scale.—*Rio News*, Sept. 7.

On the Albertina plantation near Ribeirao Preto the buildings, machinery and 50,000 arrobas of coffee were recently destroyed by fire.—*Ibid*, September 14.

CEYLON TEA IN NEW ZEALAND.

We have a letter from the representative of one of the first houses in New Zealand—"the Hondai-Lanka Tea Co."—to go in for Ceylon teas, complaining of the frauds which are now practised in reference to the packet trade in our teas and calling on the Planters' Association to deal with the matter. Our correspondent tells us he has sent to his agents in Colombo a sample packet of tea bearing the words "packed in Ceylon and C. B. Hall, Printer, Colombo." We know of no such printer here and it is quite evident as our correspondent declares that such packets and many more besides, sold in New Zealand, as "packed in Ceylon," are really made up locally in Dunedin and other towns with blended teas. In most cases, as our correspondent indicates, nothing can be done to stop this practice; but the packet he sends over with an unknown (false) printer's name, gives an opening for steps to be taken, since the firm or firms selling such packets can be exposed and even prosecuted if our Planters' Association choose to move in the matter. The tea in the

packet we hope to have tested and reported on when it reaches the Colombo Agents: it has not yet come to hand. But meantime our correspondent adds:—"The best thing your Planters' Association (or Committee of Thirty) can do is to send over an agent to prosecute the houses in New Zealand selling spurious or blended, as pure Ceylon teas. New Zealand is now one of the best markets for your teas; but unless this system is checked, the trade will speedily fall off; for blenders are rapidly importing Fiji tea and calling it Ceylon." We commend the above suggestion to the "Committee of Thirty." A single prosecution in New Zealand could not fail to have a good effect all over the Australasian Colonies as well.

DEVELOPMENT OF NORTH BORNEO.

Amongst the passengers who arrived in Colombo by the ss. "Friedrich de Grosse" were Mr. and Mrs. Fryer, who are returning to North Borneo. Mr. Pryer has lived there for twenty years and is the oldest European official in the island. He is the representative of the North Borneo Development Co., of which Lord Waterpark is chairman, and which owns 100,000 acres of land, of which, however, only some 1,500 are brought under cultivation at present. He is also associated with the Borneo Trade and Planting Company, the chairman of which is Mr. H. A. Scrutton. Mr. Pryer's errand at home has been to arrange for the further development of the large estates of the two companies and to engage European assistants, several of whom will join him en route or meet him on the island shortly after his arrival.

The large area of land, which the two companies have secured, is mainly situated on or near to the seaboard near Sandakan. This, Mr. Pryer claims, is one of the finest harbours in the world, almost landlocked, with an even depth of water and situate so as to be safe from violent winds. Vessels call on their way to and from Hongkong and Australia, but at present the trade is not sufficiently developed to enable them to call regularly at frequent intervals. The land that has been put under cultivation has been mainly devoted to coconuts and has been profitably employed, but experiments have been made in

COTTON CULTIVATION.

And it is intended, in view of cotton mills, started or to be started in China and Japan—the supplies for which are mainly derived from India—to make a commencement on an extensive scale. The cotton plant is indigenous to Borneo and the cotton that grows is much the same as Egyptian in staple, while it will realise in the home market a penny per lb. more than the ordinary American. That was the verdict at any rate of experts in Liverpool, who had the samples recently submitted to them. In Borneo, American cotton cannot be grown because the rain that falls, spoils the produce, but this does not prove to be so with the cotton indigenous to the island, which resembles Egyptian. Another development is to take place in the cultivation of

MANILLA HEMP

which is so largely exported from the Phillippine islands, where the export duties are so heavy and the restrictions on trade so vexatious. There are also other exactions there grievous to be borne, but at Borneo, under the British flag, all is free and everything that can be done to promote trade is done by the representatives of the

Government. Hitherto there has been a difficulty in securing suitable labour for this crop, but there is now a rebellion in the Philippines and it is believed that one of the results of the troubles there will be that there will be in Borneo a large influx of rebels, who, under a free and settled government, with the certainty of fair wages, will soon settle down to regular work. It is hoped that in five years Borneo will be exporting Manilla hemp to the value of £1,000,000 sterling, and that in ten years the island will have virtually secured the trade now enjoyed by the Spanish colony. Another advance will be made in

RUBBER CULTIVATION.

In regard to the demand for which, there have been of late such rapid developments. Rubber is indigenous to North Borneo, the kind most commonly grown being Willoughbeia. There is already some exported and Mr. Pryer has secured twenty thousand seeds so that as soon as he lands steps will be taken to place an increased acreage under cultivation. Such are some of the anticipations Mr. Pryer has formed and our readers will join us in wishing him success in his enterprises. Mrs. Pryer was met at Colombo by Mrs. S. H. Dyer, of Kotagala, who is her cousin.

FACTS ABOUT TEA SEED.

[Contributed.]

To those who have billets on seed gardens, as also to those whose gardens are purchasers, there is little mystery in the manipulation of the annual crop. But as I myself have been often asked how it is done, and others having, I presume, been in the same predicament, there are many to whom the "history of the mystery" may possess some little interest. On the seed gardens the time and season comes round and passes away without causing any undue bustle. We look upon it as a matter of course and get ready for the crop as others at the beginning of a tea season put their machinery and leaf houses in order. The matter is simplicity itself.

About the middle of September the seed begins to fall, and previously to this we have cleared all the jungle from the foot of the bushes, so that picking it up may involve as little trouble as may be. As soon then as the first signs appear the children and some of the women are put on to grope for what they can get. At first this is little, but the seed ripening the night breeze of falling seed shakes down more and more until there is sufficient to justify the cleaning preparations in view of the first chillan; so we spread the seed out in the sun and down beside it plant such of the garden labour force whose physical incapacity for arduous labour best fits them for the matter in hand. These strip off the outer skins and throw the cleaned seed into basket. Next day the cleaned seed is put little by little into a tub of water. Such as floats is thrown aside and that from the bottom and floating in mid water is gathered up and spread on *chalnies* to dry. Some make a second quality of the mid-water seed, and keep it separate. Dried the seed is buried in layers in beds of clean dry sand heaped up on a leaf house floor, ready for packing. The seed ripening still further artificial assistance is necessary to cause it to fall, so some able-bodied men are put on to give the trees a good shaking. This brings

down a lot, and soon we are in the thick of our season, cleaning, sorting and packing as fast as we can.

The packing requires a little care in its supervision. We here use tea chests cut in half, as we find, filled with half a maund of seed packed in charcoal, lidded, nailed down and bound with iron, the finished chest turns out just a maund. This is as much as the despatch service allows.

The mistri first cuts the boxes in half. The bottom half is then taken, and the bottom and all four sides lined with stout paper. Then a layer of charcoal is dropped in thick enough to bed a seed in. Ideas vary as to the best transporting medium. Some use charcoal, others charcoal mixed with sand or earth, others, again, light dry earth only. On the first layer of any of these seed is scattered as close together as may be but not lying double. This is covered with the packing mixture and another sheet of paper laid down. Then the operation is repeated until the chest is full up, and a final sheet of paper is put down under the lid.

The seed and charcoal or otherwise are weighed out for each box, and one or two seed taken out from each as a test to determine the percentage. Now in this testing much difference of opinion is shown, and until a uniform method is agreed on it is as well in agreeing to a minimum per cent good, to know now this will be arrived at. This is the usual method. Take one hundred seed, and breaking the shells, split them open into the two natural halves. Then all absolutely bad is counted out in one row, so many as are "spotted" in the second, and the good seed is in the third. The bad is at once counted out. In the spotted two out of three are counted good, and these, plus the third good row, give the percentage. This is a very fair method, and is usually accepted. The difference of opinion lies in the spotted seed. Some men testing will count out the absolutely bad as before and into this count all seed spotted near the germ. Those spotted away from the germ, on the other hand, being reckoned all good, there is not very much room on the surface of an opened seed, and the meaning of the word "near" may be read differently as one is seller or buyer. It is a delicate matter. Others again—these being buyers—will split a seed into four lest any imperfections should remain hidden after a single cut.

The boxes are hooped, marked and sent off by the quickest route. The price runs from sixty to two hundred rupees a maund, and a further charge of rupees three per chest is made for packing. The expenses of collecting it on the garden are small, so the profit is—fair. First, however, catch your seed.—*The Planter*, Oct. 9th.

SIERRA LEONE COFFEE AND COTTON.—One of the most interesting of the economic plants of Sierra Leone is the highland or native Coffee (*Coffea stenophylla*) which though discovered about a century ago by Afzelius, was not described until 1834, and was not introduced into this country until sixty years afterwards (1894). It was figured in the *Botanical Magazine* (t. 7475), and described more recently in the *Kew Bulletin* (1896, pp. 189-191). This coffee has been widely distributed from Kew. It has lately flowered in the West Indies, and is there regarded as likely to prove useful for cultivation in lowlands where the Arabian coffee will not grow. Another promising economic plant in Sierra Leone is the native cotton, probably *Gossypium herbaecum*, L. In order to supplement this an effort was made some years ago to introduce the cultivation of the Egyptian cotton in the colony.

TEA COMPANIES AND DIVIDENDS.

THE NEW DIMBULA COMPANY.

We call attention to the Directors' Report of this Company for last year. It indicates continued prosperity notwithstanding adverse exchange and a lower average price for tea. The "New Dimbula" is one of the strongest Companies connected with Ceylon, and much credit is due to Mr. Dick-Lauder and his staff for the admirable management of the Company's extensive property, which now includes over 2,300 acres of tea. The Company has three classes of shareholders A. B. and C. and it will be observed that the first two have dividends at the rate of 16 per cent per annum divided amongst them; and the third 14 per cent; while after deductions for planting extension, some £3,000 are carried to the reserve fund. Among the home Directors we always think of Sir Arthur Birch, and Mr. W. Herbert Anderson (the Managing Director) in connection with this Company and its good management. It is in every way a credit to the Colony.

Few Companies give so much information about its operations as "The Consolidated Estates Coy., Ltd.," whose Report also finds a place in this issue. The interests of this Company are spread over a good many districts—Dimbula, Kotmalie, Hewaheta, Nilambe, Matale and Kalutara—and it has now 2,711 acres of tea in full bearing, 129 partial with 334 acres recently planted, besides some cardamoms and cacao. The crops of the past year have been excellent (and the prospects are good), but a lower average price for tea with adverse exchange has led to a reduction in dividend from eight per cent. in 1895-6, to six per cent. in 1896-7. The strictest economy is to be exercised during the current year, in order, if possible, to counterbalance exchange. We need scarcely say that with Messrs. Geo. Stenart & Co., as agents in Ceylon, and Messrs. Arbuthnot, Latham & Co. in London, the interests of "The Consolidated" are in good hands.

One has never heard much of "The Korala Tea Estates Coy.," and indeed it only dates from May 1895, when Riverside, Glenloch, Karagastalava, Wewesse and Debedde estates were taken up and the Company formed. The Report now published is not pleasant reading; but we trust there are better times in store for this Company as indeed for all Ceylon Companies.

PLANTING NOTES.

ROYAL GARDENS "KEW BULLETIN," of Miscellaneous Information. Contents for October is as follows:—Botanic Station, Sierra Leone; Improvement of the Sugar-beet and Sugar-cane; Forest Products of Sierra Leone; Butter and Tallow Tree of Sierra Leone; Coffee Cultivation at the Gold Coast; Botanical Enterprise in West Africa; Miscellaneous.

WHAT THE COFFEE PLANTER HAS TO PUT UP WITH.—Professor A. W. Stokes, the public analyst for the borough of Hampstead, says in his annual report to the vestry of Hampstead, which has just been printed: "Coffee showed an adulteration of 8½ per cent of its samples, by means of from 50 to 60 per cent of chicory. It is usually said that the buyer prefers a mixture of chicory and coffee. This may be true; but when the buyer asks for 'coffee' he ought not to get the mixture. But so long as coffee costs twenty pence and chicory only four pence per pound the temptation to some vendors to think the buyer means a mixture when he says 'coffee' will be irresistible."—*H. and C. Mail*, Oct. 22.

FROM TEA TO COCONUT PLANTING.—Mr. T. Patterson, employed on Holmwood estate, Agrapatnas, purchased on the 13th October last a block of land containing about 97 acres between Negombo and Mirigama. He intends to leave Holmwood, after fourteen years as conductor and assistant superintendent to take charge of the new block and plant coconuts and Liberian Coffee.

WEIGHT OF COCONUT CROP PER ACRE.—Our correspondent "D" writes:—"You were asking about the weight of a crop of coconuts. Taking 4 lb. as the average weight of a fresh coconut, and calculating 3,000 per acre per annum, for an average crop, the weight of the produce will be something over 5 tons." We are much obliged to our correspondent: now for "cinnamon" sticks and all?

SCIENTIFIC RESEARCH.—We understand that Mr. D. Hooper, formerly so well-known as a clever Chemical Analyst at Ootacamund, has established a research laboratory in the Indian Museum in connection with economic products. He will be allowed by the Trustees to undertake on a small scale private analyses of cinchona bark and other organic produce. It is a pity that the Madras Government could not see its way to retain his services in this Presidency, but, though further off, Madras planters will, we fancy, be only too glad to re-avail themselves of his invaluable services.—*Planting Opinion*.

GUANO IN THE SEYCHELLES.—By a recent mail we had a letter from Mr. John Hughes in which, *inter alia*, he mentioned:—

"I have this week completed the analysis of a Phosphatic guano forwarded me from the office of the Crown Colonies in Downing Street. The sample was forwarded from the Seychelles Islands. I don't know whether the results will be made public or not, so I had better say no more, but it may be interesting to know that a phosphatic guano exists in these islands, to what extent I do not know.

"I am very busy with agricultural analysis as the rise in the price of wheat has given quite an impetus to the manufacture and sale of manures."

COFFEE AND CACAO CULTIVATION AT THE GOLD COAST.—A good deal of general work has been done in the Government Botanical Station during the year and considerable attention has been paid to the plantations of coffee and cacao, in the cultivation of both of which, but more especially the former, the natives appear to have become interested. Along the road leading from the Botanical Station through the country of Akwapim to the interior are large numbers of small clearings in which coffee plants, chiefly obtained by purchase from the Botanic Station, are to be seen in a most flourishing condition. The Liberian coffee plant appears to thrive best, but there are large quantities also of the Arabian coffee plant, the berry of which, however, is small and apparently deteriorated. It will probably be necessary for the Government at no distant date, if the coffee industry is to be fostered into a trade, to instruct these native cultivators in the proper way of preparing the berry for export. At present the most primitive method is employed. The berries are scraped by hand with a round stone worked in the hollow of a larger stone, and after this process they are washed and dried in the sun. It is obvious that a large crop could not be so dealt with, and that the employment of machinery in the near future is imperative. During the last two years the Government has introduced machinery for pulping and curing coffee, and consignments of both coffee and cacao have been forwarded through the Crown Agents for sale in the London market. This plan afforded the best means for testing the commercial value of the produce, and it is gratifying to find that the result shows that coffee and cacao can be grown in West Africa capable of realising good prices in European markets. Much still remains to be done to induce the natives to cultivate and cure their produce in a satisfactory manner.—*Kew Bulletin*.

THE COCONUT INDUSTRY.

In view of the references which have lately appeared, from time to time, in our columns on the disappointing prices which rule for coconuts, and in continuation of our article on page 381, it may be of interest to note the change which has come over the oil industry on which the price of nuts most largely depends. Although the Desiccating Mills consume what a few years ago would be considered an immense number of nuts, yet, we saw in our review of last year's exports that the Mills accounted for only about 30,000,000 nuts, while the Oil exports represented 171,000,000 nuts—a figure much below the requirements in previous years. The new Desiccating industry has undoubtedly helped to keep up prices; but it has chiefly benefited estates in the neighbourhood of the Mills, as these save the cost of transport while they realise the same price for their nuts as estates situated at a distance. Oil, therefore, has practically ruled the price of nuts; and even proprietors who have found it advantageous to sell to neighbouring Desiccating Mills complain of the serious fall in price. From one of these we learn, that the difference between this year's and last year's prices averages between R4 to R7 per thousand for separate crops; while the difference is as much as R6 to R10 and even R12, compared with the prices of 1895. Does the difference in the value of oil then and now explain this immense fall in the price of nuts? Not wholly, we think; because the gold price of oil has remained about the same, and the difference is mainly connected with the rise in exchange which cannot account entirely for the lower prices which rule for nuts.

Let us look now at the Oil exports up to 26th October, the latest figures available, we find that the quantity sent away from the island, (300,857 cwt.) is greatly in excess of the quantity exported during the corresponding period of last year, which was 262,818, and little less than in 1895 which showed 310,168 cwt. The figures for the corresponding period of 1894 are 385,616 cwt.; but the shipments that year were exceptionally large and were exceeded we believe only once, that is, in 1892. The present year has thus been one of high average exports for oil; and there is nothing in the quantity exported to explain the price of nuts. The ruling prices for oil have, however, evidently stimulated the demand; and it is on this fact, perhaps, that the hopes of the Coconut Planter must primarily rest. When we turn to the table of distribution, we find that our oldest, and till recently largest customer, the United Kingdom, took from us only 58,770 cwt. as against 68,285 last year; while America, our next best customer for many years took about the same quantity, 52,124 cwt. against 51,570; but India has more than doubled her demand with 135,723 cwt. against 64,961 last year. Singapore too, has made a stride from 32,921 cwt. to 37,566. These two neighbours of ours have thus absorbed more than one-half of our exports, evidently under the stimulus of low prices which are traceable to cheap and abundant tallow in Europe and America. When once the substitutes for coconut oil in the European and American markets rise in price, the demand for our oil, we suppose, will im-

prove; and with that the competition between our new customers and old should lead to better prices.

There are two hopeful circumstances connected with the trade with India and Singapore—that the oil is chiefly required for culinary purposes, this fact pointing to a regular demand; and, secondly that they have found our oil cheaper than Cochin oil; while, for Calcutta and Singapore, it is somewhat nearer at hand. On this point, it may be well to quote from the communication of a Coconut proprietor who had, curiously enough, written what follows before he had seen our last article. He says:—
 “It has always been a puzzle to me why
 “Cochin oil should be so much dearer than
 “ours. The explanation offered, that the Cochin
 “Oil is richer in stearine, affords no information
 “as to why it should be so; and whether, by
 “improved cultivation or improved manufacture,
 “Ceylon may not secure for her oil, too, the pre-
 “eminence she enjoys with almost all her products.
 “Our oil might certainly be whiter; but the natives
 “have an inveterate habit of resorting to methods
 “which give them the least trouble; and, in the dry-
 “ing of copra, the easiest method is to split the nuts
 “and put them on a low platform with fire under.
 “This blackens the copra, and the resulting oil
 “is of a darkish yellow colour. Careful drying,
 “even over a fire, may yield clean white copra;
 “but it is seldom the necessary care is observed,
 “and some of the blackened stuff which is offered
 “for sale, and readily purchased, is a disgrace to
 “the producer. I do not say that all our copra
 “can be sun-dried, because on a showery or cloudy
 “day, the nuts in process of drying must be dried
 “on a platform or they would turn mouldy and
 “be discoloured; but what the mills might do is
 “to offer higher prices for sun-dried copra, and to
 “make oil separately, of the clean white copra
 “and of the black. As it is, though higher prices
 “are paid for clean copra, without reference to
 “its being sun-dried, good and bad are mixed;
 “and hence the oil is not white. May not a dif-
 “ferent system, save our reputation, and place at
 “least some of our oil on a par with Cochin; for,
 “in the Northern ports, at least, of the Island,
 “sun-drying might be made the rule, if higher
 “prices are paid for sun-dried copra, and white oil
 “is manufactured separately? Then, can smoke
 “drying have any effect on the stearine? Is it not
 “the fact that Cochin oil prices are due partly to
 “operations in the market, though it is decidedly
 “superior to ours?”

These are interesting questions, and we are taking steps to get answers on several points involved—the first of which, indeed, we append. For the present, it is the shifting in the distribution of our Oil to which we wish to draw particular attention, both as a curious fact, having regard to our proximity to India and intimate commercial relations with her, and also as one which gives promise of competition with our older and larger customers for oil. In Desiccated Coconuts our exports are steadily growing and so in Coir. We have no reason to complain of the quantities of Coconuts removed in the shell, which are almost, if not quite, the highest on record; while in Copra we are far ahead of previous years. There is thus an abundant demand for the growing supplies, from the Island of the varied products of the Coconut palm; but what has to be done now is to introduce the Cochin mode of sundrying Ceylon Copra, wherever and whenever possible.

COFFEE PLANTING EXPERIENCE IN
B.C. AFRICA.

As, occasionally, misleading accounts of British Central Africa, and its prospects as a Coffee producing country appear in newspapers in various parts of the world, written in many instances by visitors who have merely passed through the Shire Highlands, and gathered their opinions from more or less reliable sources; we have for sometime past desired to obtain the actual experience of some leading coffee planter in the country, accompanied by accounts of expenditure and results which could be thoroughly relied on.

We recently asked Mr. S. Israel of the Chipande Estate, (now also manager of the various estates of the firm of Buchanan Bros.) if he would be willing to supply us with such notes and accounts; which he kindly consented to do; and these we publish below.

These are the actual experiences of a B. C. A. Coffee planter.

Mr. S. Israel arrived in British Central Africa in June 1894. In July 1897 he had 180 acres planted, the first 60 of which brought him this year 20 tons of coffee. He thus obtained a substantial return, three years and a month after first reaching B. C. Africa. In Mr. Israel's case a very large proportion of his expenditure has been incurred in erecting substantial brick buildings, stores, sheds etc. all of which could have been, dispensed with by a planter anxious to expend as little as possible until his returns came in.

The amount of expenditure in cultivation up to date is also, we think, considerably heavier than would be incurred by most B. C. A. planters on a plantation of similar size.

In the face of statements we have recently seen, made by a correspondent of the *Ceylon Observer*, to the effect that B. C. Africa is no coffee country, poor soil, no successes, and so on, we are glad to be able to publish an authentic statement of a practical planter's experience in this country. The following is what Mr. Israel says:—

"Being led by your wish, and also being requested by friends at home to give a statement of my progress in B. C. A I have no hesitation in doing so.—The enclosed Balance Sheet and Estimates will speak for themselves; but I add the following explanatory notes.

"(1) The extent of my Estate is rather more than 500 acres, but this area is all required for opening such a coffee Estate as my own. I purchased the land at less than 7/- an acre, but this being at least the present value of good coffee land so near to Blantyre I think I am justified in taking that figure as a basis.—

"(2) To open up a Coffee Plantation, permanent buildings are not required, until success may be reasonably expected. No valuation has been made by me for any temporary improvements nor has any labour or profit been taken into consideration chargeable or due to outside transactions.

"(3) The expense of transport of coffee to the river port is included in wages for garden labour, and the valuation of £70 per ton for well-cured coffee will not be above the value, probably less.

"(4) The valuation of coffee land opened up may be considered by some too much, by some too little, but to bring the returns into account, I consider it fair. In valuing the younger planted coffee at £3 per acre less I was guided by my intention to spend this sum per year on that portion of the land.

"(5) The sum of £510 expenditure per year, put down by me allows for all labour, and for the purchase of manure.

"(6) The expenses provide for thorough cultivation of the soil; and the returns exclude first maiden-crops which always have been stripped off the trees by me.

"(7) The estimate on returns of such coffee as has borne a first crop, I only put down for second bearing at one-eighth of the first year's returns while in the third year, when the manure will act better, secondaries on the trees being properly established, I anticipate a heavier return.

"Although I have made a valuation of my own plantation I would remark that such a value is placed on it by me for the purposes of this estimate only, and that I would decline an offer made at my own valuation.

"Being one of the younger settlers of B. C. Africa I must take this opportunity to apologize to older pioneers, should they consider that I wish to lay down the law, as to how to make coffee planting a success.

"I only give my own opinion founded on my own experience, and I am confident that, by planting shade, and light manuring, this country will become one of the best, though possibly not one of the largest coffee producing countries of the world."—S. ISRAEL.

(Sd.) S. ISRAEL.

Blantyre, August 16th. 1897.

—B. C. Africa Gazette, Sept. 7.

COFFEE IN BRITISH CENTRAL AFRICA.

BLANTYRE AND CHOLO DISTRICTS.—Mr. Jonathan Duncan, the pioneer coffee planter of British Central Africa, states that the coffee crop for 1897 is good, and that the amount exported from B.C.A. is sure to increase year by year, as a large quantity of fresh land is being opened up all over the country. He states that coffee is a somewhat precarious crop, and that one thing to be avoided is that the young trees should be allowed to bear too heavily. If this is done, he states, the result will be no crop for two or three years following the first heavy one, as it takes that length of time for the plants to recover themselves. Mr. Duncan is an advocate for shade.

From Messrs. Lamagna we hear that the Mapemba and Ntonda Hill Estates, gave a crop of 40 tons in 1896. The same trees are giving a better crop this year, and are looking healthy and strong.

About 120 acres more were opened up on the two estates, 80 at Mpemba and 40 at Ntonda Hill. Close to these two estates the firm has the Portenope Estate opened in 1896, on which 120 acres are planted.

On the slopes of Michiru Mountain facing the Upper Shire, they have the Tumbulumbo Estate, which in 1896 gave a crop of 9 tons from 60 acres. The same trees this year are giving about the same crop, perhaps a little more. Mwalanduzi Estate in Cholo (belonging to the same firm) gave 6 tons last year and 10 or 12 tons are expected this year.

On their estate at Nkawa (Cholo) they opened last year about 100 acres and were expecting this year only a maiden crop of some 4 tons from 40,000 plants which were planted in 1895.

Messrs. Lamagna tell us that the export of coffee will show a steady increase from year to year, and they also state that:—

“Although nobody is yet able to lay down a single rule, we mean a hard and fast rule, much less any fixed laws about coffee planting in this country, for the simple reason that the industry is too young yet, and we are without sufficient data extending over a number of years to go on, still from the experience of these last 3 years, we may safely say that coffee planting in B.C.A. is or can be made to be a perfectly safe, steady, and paying enterprise, a thing that cannot honestly be said of many colonial undertakings.

“One main advantage of course is the abundance and comparative cheapness of the labour supply and the soil is at any rate moderately fertile and as yet unexhausted, so that for a few years to come it will, unaided, yield fairly satisfactory crops—but naturally we must look ahead of us, and ensure a continuation of these crops; which can be

done by manure and shade.—those two most necessary helps to nature, which are being tried on various estates. Several kinds of shade trees are being given a trial; and in the course of the next two or three years we shall be able to determine what are the best shade trees for this country, and also what effect manures have on the growth and yield of our coffee bushes, and what sorts it is advisable to use in preference to others. Conscientiously we think this is all that can be said at present on the matter of the coffee growing industry, which however, should be highly satisfactory to any who intend starting plantations here or so investing their money.

“Although it might be said that the export of coffee in B. C. A. is increasing yearly simply because every year new estates come into their first bearing, still at the same time the same estates have proved to be able to bear crops for a succession of years. We think that with careful management and hard work an estate can be made to pay from 12 to 20 per cent. on the capital invested.

“Now, as far as regards ourselves, the following is a statement of our estates with their acreage (of course all at various stages of growth) and their estimated crops;—”

Alpenba Estate (I. Lamagna & Co., and others) acres planted, 400; crop expected in 1897, 30 tons.

Ntonda Estate (I. Lamagna & Co., and others) acres planted 300; crop expected in 1897, 25 tons.

Partenope Estate (I. Lamagna & Co.), 120 acres newly planted.

Mwalanduzi Estate (Lamagna and McKinnon) acres planted, 200; crop expected in 1897, 10 tons.

Nkawa Estate (I. Lamagna & Co.,) acres planted, 200; crop expected in 1897, 4 tons, (from 40,000 plants.

Tumbulumbo Estate (I. Lamagna & Co.,) acres planted, 200; crop expected in 1897, 10 tons.

Makungwa Estate (Messrs. Josselin de Yong & Visser) acres planted, 170; crop expected in 1897, 17 tons.

Mr. J. Lindsay, the manager for Mr. E. Ch. A. Sharrer, and also a planter himself, states that the prospects of crop are somewhat injured by the fact that when the blossoms were setting last year they had prolonged drought, and also locusts did considerable harm by settling on the primaries and destroying both flower and bud.

The extensions planted out in the early part of this year amounted to 300 acres, bringing the total amount of land under coffee cultivation by this firm to 1,800 acres. It must be understood that about half of this has not yet reached the bearing stage, and that 200 acres have only reached their maiden crop.

Mr. R. S. Hunter, the late manager of the firm of Buchanan Brothers, and also the owner of plantations in the Blantyre and Cholo districts, estimates the 1897 crop at 450 tons or a little less. He states that about 10 new plantations have been opened up, though very few new planters have come into the country during the last year. Thus he considers must be due to the deaths of the two Buchanan Brothers, whose names were so widely known that the fact of their deaths—both in the same year—has given a worse impression as to the unhealthiness of the climate of B. C. A. than it actually deserves.

Mr. Hunter states that about 2,000 acres have been opened up in the past year, a large portion of which has been done in the Cholo District. He thinks that the 1897 crop would have been much heavier had it not been for the unprecedentedly hot and dry weather during the last blossoming season. Mr. Hunter informs us that planters generally in B. C. A. seem to have come to believe shade to be a necessity, and in certain districts which have a short rainfall he thinks it most essential.

Shade has been largely planted in the various districts of the country, the *Grevillea Robusta*, and varieties of the *Ficus* apparently being the most popular, although the *Albizia* has also been largely planted.

Mr. Hunter informs us that the labour supply during the present year is a most gratifying feature to coffee planters, also the improvement in navigation on the Lower Shire river which has taken place in 1896-97, now makes it possible to ship coffee home expeditiously and safely.

THE ZAMBEZI INDUSTRIAL MISSION.—Mr. Alexander Hamilton of the Z. I. M. has furnished us with the following notes regarding the large coffee plantations belonging to this Mission.

"In the 'Notes' I do not see much said about Trenching. I think this is one of the most necessary, because one of the most beneficial works, that can be carried on in connection with coffee culture, especially in this Land of Drought where the sky is unclouded for so many months in the year.

"Every plantation ought to have a systematic course of trenching every year. It should be gone over at intervals, say four or five times in the course of the year, during the dry season, as well as the wet. Those who have seen the good effect this has on the plants, will know the efficacy of it.

As some information as to the planting industry of the Zambezi Industrial Mission was requested I will try to give it briefly.

"On the Michiru Estate we have four planting centres, viz:—

- (1) Mitsidi (Headstation) with 220 acres planted.
- (2) Ailsa Craig, with 125 acres.
- (3) Maliya, with 45 acres.
- (4) Chilingani, with 15 acres.

In South Angoniland we have four stations growing coffee:—

(1) Lisungwe. We do not count the acreage on this station, as it has not had a fair chance yet, to know whether it will do or not.

(2) Ntonda, with 128½ acres.

(3) Chirole, with 96 acres.

(4) Dumbole, with 66½ acres.

"The total for the Z. I. M. is thus 696 acres. These are our returns for the year ending 31st March, 1897. We expect at end of next planting season, to have fully one million plants growing in our combined plantations.

"As to the prospects of coffee being successfully grown in South Angoniland, I have very few doubts. I think Chirole Plantation, for instance, will compare favourably with any its own age in other parts of B. C. A.

"The first coffee planted by the Z. I. M. in South Angoniland was during the wet season of 1894-5 and amounted to 15 or 16 acres. This is now in full bearing and is giving a heavy crop. So that this year, another part of B. C. A. enters the market as a coffee producing district. The first sample which has been produced shows a very good bean."—*B. C. Africa Gazette*, Sept. 7.

Regiment of Malay States Guides forms, of course, a large part of the Federal Expenditure, but, on the other hand, the cost of the police in the various States has been diminished by the removal of their charges from the States to the Federation.

Mr. F. A. Swettenham, in the course of his annual Report, says:—

Since last June I have travelled close upon 7,000 miles, in and about the Malay States, and I have therefore had opportunities of seeing, not only the work being done under Government control, but also the operations of private individuals. I have been specially struck by two things; European planting in the Negri Sembilan and European mining in Pahang. Planting, especially the cultivation of Liberian coffee by Europeans, Chinese, Malays and Tamils, has made great strides during the last two years. The evidences of this forward movement will be found in all the States, even in Pahang, but I think the progress is most notable, or it may be only noticeable, in the Negri Sembilan. I am personally very glad that this is so, because I do not myself regard the Negri Sembilan as a State rich in minerals, and it is therefore fortunate that it has attracted planters. It is equally satisfactory to know that one must go to Pahang to find the greatest mining enterprises in the Peninsula. Pahang is the State where we want to see progress, for it is deeply in debt, it is backward in every respect, and fears have been expressed that it was likely to prove a millstone round the necks of its helpful sisters. I do not share those glooms forebodings. One of the best Chinese mining capitalistry in the Peninsula has very recently come to terms with the Government of Pahang, and proposes to begin extensive tin mining operations in the Bentong district. If he carries out his present intentions and is successful (the prospects are encouraging) great advantages must result from this undertaking. But it is as a gold country that I think Pahang will presently become favourably known; a country where companies with capital and skilful management will make considerable profit.

With the extension of planting operations, the labour question has become one of such importance that, if the Governments of the Malay States really meant to encourage planters, it was evident that something must be done to help supply them with labour. It is not a new question, and the Malay States have never been backward in their desire to take a fair share of the cost of introducing immigrants into countries which possess no sufficient or reliable labour supply of their own. But unfortunately the matter did not rest with them; it was necessary to secure the sympathy and assistance of the Indian Government, as the source from which the best supply was hoped to be obtained. Whilst the question was discussed, year after year, Government works, especially roads and railways, could not wait, and, so far, the Government, either departmentally or through contractors, has taken advantage not only of the free labour that came into the country; but, I fear, to a considerable extent, of the labour introduced by planters in the Colony and Malay States. Now, however, there seems a prospect of better things, and the Federated States have this year undertaken to find a considerable sum of money to introduce Indian immigrants, to strengthen the force of labour available for their own works and the needs of the community. I trust no further difficulties will arise, for the number of large estates now being opened in Malaya increases so rapidly that the scarcity of labour is likely to be increasingly felt, and if, as not uncommonly happens, the price of produce falls, the present high rate of wages cannot be maintained.

NEW INDUSTRIES.—The price of tin has fallen, and the price of Liberian coffee has fallen, and though miners in Malaya can produce tin, and planters can grow coffee, and make a profit at existing prices, it is distinctly advisable that we should increase the number of our productions, and not rely on these alone. As regards mining, there is gold, and that will probably take care of itself; but we have had to encourage agriculture, and it will probably pay us to

PLANTING, LABOUR, &C. IN THE FEDERATED MALAY STATES, STRAITS.

In forwarding the Report of the Resident-General (Mr. Swettenham), Sir Charles Mitchell, as High Commissioner, said:—

This account of the progress of the Federated Malay States, during their first half year, contains, I submit, a record of much good work done, and fully justifies the important step taken on the 1st July of federating these States. So far as I have seen, the chief drawback to the new system is that questions requiring my decision are sometimes a long while in reaching me, but this is inevitable, and will diminish with every advance in developing the means of communication. I cannot speak too highly of the tact and ability shewn by the Resident-General and by all the Residents in overcoming difficulties, diminishing friction, and generally promoting the success of the Federation. The expense has been a good deal greater than I anticipated, but the greater part of it is of the nature of capital expenditure in providing quarters for various Federal Officers. The charge for the

continue that policy. The climate and soil of the Malay States are suitable to most tropical products and, when a successful experiment has been made, imitators are never wanting. It is probable that, in the near future, there will be a great demand for rubber, and while many valuable species are indigenous here, amongst them the *pinus elastica*, which grows like a weed, others have been introduced from South America, and shewn to do well. That is one of the benefits conferred on the country by Sir Hugh Low. Excellent tea has been grown and manufactured in Perak, Arabian coffee of a high class has been produced on the mountains, and, when a cart-road has been carried into the highlands that divide Perak from Pahang it is probable that other paying forms of agriculture will be introduced.

SIROCCO TEA MACHINERY.

We have received from Messrs. Davidson & Co. of the Sirocco Engineering Works, Belfast, an illustrated catalogue of their special tea machinery and also a letter upon the subject. The catalogue is no dry record of the appliances for preparing tea, but an interesting and well printed hand-book, descriptive of the Sirocco works, with portraits of the heads of the various departments. Amongst these are those of Mr. F. G. Maguire, chief visiting engineer of the Colombo branch and Mr. H. M. Harris, formerly of Ceylon, who is now commercial manager of the Calcutta branch. We commend the pamphlet to the attention of anyone interested in tea.

PLANTING AND PRODUCE NOTES.

THE WEST INDIES AND TEA CULTIVATION.—In looking through the report of the West India Royal Commissioner and the subsidiary report by Mr. D. Morris, assistant director of the Royal Gardens, Kew, we find no mention of any suggestion that West India planters should turn their attention to tea cultivation. There are suggestions made as to the development of subsidiary industries other than sugar, but nothing is said about tea. Coffee, tobacco, and fruit cultivation are freely recommended, but, presumably, the Commissioner did not see any prospects for tea cultivation either in the West India Islands or in British Guiana.

THE USE OF THE BANANA.—No doubt its cultivation will be overdone, but at present there is a keen demand for bananas in the United States, where the baked fruit is being extolled in America as the ideal food both for the nervous, the anæmic, and the brain worker. Bananas, it will be remembered, occupied a high place in the diet of the late Sir Isaac Holden, and without going so far as to say they are a panacea for all ills, it is asserted that their great power to sustain mental effort is recognised in India.—*H. and C. Mail*, Oct. 15.

COCHIN Vs. CEYLON COPRA AND COCONUT OIL.

(Answer to Circular.)

One reason for Cochin oil fetching more than Ceylon oil is, that the process of manufacturing it is quite different in the former place from that of the latter. Cochin nuts are smaller than Ceylon nuts and the outturn of oil is roughly speaking about cwt. 2½ per candy for Cochin against cwt. 3 for Ceylon. The Coconut area in Cochin is small as compared with Ceylon, and more care is taken there in the plucking and the drying of the nuts. Only ripe nuts are plucked and the kernel is cut into slices, and carefully dried in the sun. All unripe and bad nuts are removed and only the good clean white copra is manufactured into oil. This is

the white oil of Cochin and it is used in some parts of India as a substitute for ghee. Monsoon-made oil sometimes fetches the same price as white oil, if the quality is fine, but the objection to monsoon-made oil is, that it is, as a rule, off the color in consequence of the damp weather rendering the copra liable to get mouldy, but of course there may be some fine oil made during the monsoon. Greater care in the plucking and drying of the nuts may be bestowed in Ceylon, but the area is too wide, and the climate will not permit of the proper drying of the nuts in the sun. Nuts are plucked anyhow or anyhow here, split into two and thrown to dry in the sun, and if the weather is bad, all the kernels are put on a platform and smoked, which blackens the copra and imparts to it a smoky taste. The copra is then hurried off to the carts or boats to Colombo. Little or no trouble is taken to separate the good copra from the bad nor the white from the black. All come to the mills and it is this produces the Ceylon oil.

White oil, indeed is manufactured in Colombo, but the demand is limited and manufacturers do not keep a stock of it. It fetches about Rs 20 per ton over ordinary good merchantable oil. A good deal of care is taken on some of the estates owned by well-known Ceylon gentlemen, and the copra from these properties always fetches quite Rs 1 per candy over ordinary quality. The best result would be obtained in the Chilaw District. Copra is frequently brought into Colombo from Batticaloa. The climate being dry there the shells get hard soon. It is for this reason that the nut is broken the other way, from top to bottom, for, if the usual custom was followed, the shell would get "splintered" and damage the kernel.

There is but little use, in my opinion, of either sending a Ceylon superintendent to Cochin to learn the method of manufacturing or in bringing over Ceylonese to teach the way how to do the work in Ceylon, so long as our climate is what it is. The Cochin men may lead in any thing but he cannot control the clerk of the weather. We have rain almost throughout the year and the accounts cannot be kept on the trees.* They must be plucked, and rain or no rain, the copra is made and quickly converted into cash! Some years ago a firm of mill-owners manufactured oil from selected copra brought from their own estates. This was superior to ordinary oil and always commanded in London about £1 per ton over the value of ordinary Ceylon, but this firm have now gone largely into the Desiccating line and have given up oilmaking. In this connection it must not be forgotten that copra from the Pacific, South Sea Islands, Australia and other places is imported into Liverpool and this competes to a large extent with our oil. In the sixties and seventies during the existence of Armitage Brothers and C. Shand & Co., a very large business was done in Ceylon coconut oil, the contract being sometimes for 1,000's of tons at a time. The former firm who owned Mills at Mattacooly and Mutwal were very large charterers of sailing vessels, and some of the largest ships that ever loaded here were chartered by them. The volume of business then was done direct with London, but now every thing is changed and the news telegraphed out that the stock of coconut oil was 200 tons, the month's landings 200 tons, and the deliveries 200 tons, points to what straits the business in coconut oil with London has come to in 1897 compared with what it was in 1860-70. C.

THE AUSTRALIAN SALT BUSH.—Professor Hilgard of the California State University says that the Australian Salt Bush can be grown successfully on arid and alkali lands; that it removes from the soil large quantities of Sodium carbonate and Sodium chloride, the two most injurious alkaline salts. In soils, therefore, where the percentage of alkali is near the danger point they may be sensibly relieved by planting salt bush for several seasons. The yield is nearly equal to that of Alfalfa.—*Scientific American Supplement*.

CHILLIES.

A correspondent writes:—During the past few months the prices of all food-stuffs have increased considerably, and notable among them are dry chillies, which some little time ago sold for 12c. a lb., now the market price has risen to 25c. a lb.! It is a matter to be explained why Ceylon with its thousands of acres of available land, should be dependent on the neighbouring Continent for this indispensable commodity. The cultivation of chillies is not new to the Sinhalese villager, almost every garden has a small plot planted with it and in many places where the crop is large a portion of it, in its fresh state, finds its way to our vegetable markets or is hawked about for sale by basket-women, but the process of drying and preserving the fruit, as it is done in India is foreign to the Sinhalese. The cultivation of the plant is not attended with any difficulty and does not require any special care. The requisite fertilizers being cattle-dung and dried keppettiya leaves (*croton lacciferum*.) Many years ago the late Sir Richard Morgan tried the experiment by planting some 40 acres of land in Veyangoda—he imported a few skilled labourers from India for the purpose, and if I remember rightly his experiment was a failure owing to his plants being attacked by poochies—perhaps some one who knows more of this undertaking may be able to give other particulars.

◆ ◆ ◆

NEW SYSTEM OF WITHERING TEA LEAF.

With a rising exchange and increasing cost of production, planters are not likely to be slow in their appreciation of machinery designed with a view to labour-saving economy, and inventors are very alert just now in regard to all that affects the manufacture of tea. Last week there appeared in our advertisement columns some particulars of an apparatus for withering tea introduced by Mr. Edward Robinson. As it is our province to give details of all tea machinery coming within our knowledge, we give alike for the benefit of the tea planters and other inventors of machinery a description of this apparatus, together with a statement of the claim made on its behalf by the inventor, who mentions that working models of his invention have been on view for some time in the City, and are still to be seen on application to him. He also mentions that a complete installation has been sent out to Ceylon and will be set to work without delay, and that a large number of planters have inspected his working model, and opinions highly favourable to this new departure have been expressed. He points out that an important part of the system has already been thoroughly tested in practice and has proved a remarkable success namely—the arrangements for producing and evenly distributing large volumes of warm wind. Some forty installations of this special apparatus are, it is mentioned, at work, and there are excellent testimonials respecting it. Having thus been able to secure in large buildings the exact conditions necessary for successful tea withering, the inventor has turned his attention to this widely-felt requirement, and has designed and patented an arrangement of swinging trays which he claims is not only very simple, but which introduces a distinctly new idea into the practice of using trays as spreading surfaces for withering. The new method may be briefly described thus: Strong trays, having each an area of thirty to forty square feet, and made with a frame of round iron, covered with wire netting, and all galvanised, are attached on one side by means of staples to a strong angle-iron framework. They are fixed about four inches apart, and will swing about from one side to the other like the leaves of a book.

To the side opposite the hinge-like attachment ropes are fastened, which ropes are connected to a continuous roller or windlass, carried overhead and supported by angle-iron uprights. The windlass is worked by a worm-wheel gearing, so that a boy can easily raise up a whole row of trays at once. On commencing to spread leaf the whole row of trays is made to recline backs upwards. The first of the series is then turned over by hand and the leaf spread, the same with the rest of the trays in succession. The row of trays being thus spread, a few turns of the windlass raises them all up at once to any desired elevation. It is then found that the leaf rests securely on the trays when raised to an angle of 45 deg. or even more. To about this elevation the trays are raised and left until the leaf is withered. Obviously trays standing in this position, with clear spaces of about four inches between each tray, admit of a free up-draught of wind to carry away moisture from both sides of the leaf. The air pipes are so arranged as to disperse a constant gentle current of fresh dry air under each row of trays uniformly; thus each tray gets its own supply of fresh drying wind, such wind having only to pass once between the trays, after which it is driven out through the upper ventilators by the constant incoming wind from below. Thus in bad, wet weather it is only necessary, according to the inventor, to close all doors and windows, and set heater and fan to work, and first-rate withering can be done irrespective of the weather outside. Many planters of large experience, the inventor mentions have told him that this system of withering is well calculated to save a large portion of the losses now unavoidable during heavy flushes of leaf in the rainy seasons. Should this expectation be realised it is scarcely possible to over-estimate the importance of such an improvement.

As to the great saving of labour, that, the inventor contends, is obvious on the face of it, for the spreading of the leaf upon a flat open surface some 2 ft. from the floor is much easier than the stooping down, and climbing up, and reaching between the tats necessitated by the present mode of working, whilst for gathering in the withered leaf a few turns at the winding gear raises a row of some fifty or sixty trays to an upright position, and the leaf at once shakes down upon the sheet spread out under the series of trays. The sheet is then wound in upon a simple roller having a handle and light gear-wheels. The leaf can be dropped through an opening in the floor or picked up as desired. There is nothing in the process that can break or bruise the leaf, which is another very important consideration, having regard to all the vexed questions about small siftings.

At first sight it does not strike us that there would be the saving of factory space which is claimed for this system. It is, however, a matter of simple computation, but the inventor contends that upon a careful comparison of the spreading space obtained by the new arrangement with the actual spreading space available in numbers of factories of the ordinary kind more than twice the area of spreading space is obtained under the new method in the same area of building.

It is further claimed that in the wear and tear of plant a saving of fully 50 per cent will be realised. The wire trays are never moved from their places, and the only handling required is just to swing them over for spreading the leaf. Strong trays so used are calculated to last for some years.

The inventor claims that the most important results are expected to arise from the control the system gives over the necessary conditions of withering in bad weather. When the weather is good and quite favourable for natural withering the windows of the house are opened and no heater or fan used. The arrangement of the trays he regards quite as suitable for natural atmospheric withering as the ordinary tats now in use, plus the saving of labour, space, &c. If the weather is hot, dead, and still, the fan alone can be worked, imparting a nice gentle motion and life to the air and expelling the vapour,

When the outside air is saturated with moisture and will not wither leaf a little steam can be let into the heater, raising the temperature a few degrees; vapour will then be freely carried away, and good withering done. By increasing the inlet of steam the temperature of the house can be raised so as to wither well on the coldest and wettest of days. Thus it is claimed that without in the least interfering with any existing advantages, natural or otherwise, this new system affords the planter the means of effectively withering his leaf, whatever the weather may be. The same thing is being done, says Mr. Robinson, now in numerous factories larger than any withering house on this system would need to be, the conditions obtained being identically the same as the well-known conditions required for withering tea leaf.—*H. and C. Mail*, Oct. 22.

INDIA RUBBER.

LATEST NEWS.

In an article on India Rubber in the *Indian Agriculturist* of the 1st September, we notice an extract from a paper by Mr. J. R. Jackson, which appeared in "Nature," Vol. 55, page 610. Except where this paper may be taken to refer to the few artificial plantations that have been established, it is, we regret to say, far from accurate; for it talks of the *Ficus elastica* forming large forests in India and Ceylon, while, as far as our Indian experience goes, we only find this species very sparingly interspersed in evergreen forests. The *Ficus elastica* is not sufficiently shade-enduring to permit of its germination and growth on the ground. The seed no doubt germinates very freely in the forks of trees where a little mould or debris has accumulated but in order to permit the young plant to establish itself and to become sufficiently strong to form a connection with the soil below, it is absolutely necessary that the tree on which it finds itself placed should be either dead or diseased. If not the young *Ficus* cannot obtain sufficient nourishment, and dies. That this is the case has been clearly established by experiments in the Chardura rubber plantations. Here many hundreds of *Ficus* were planted in the forks of trees. They were supplied with a considerable quantity of soil and grew to be healthy plants; but they lived the life of pot plants, and after more than 10 years not one of those growing on a healthy tree had established its connection with the soil. Now, even in a virgin evergreen forest, the majority of trees are neither dead nor so unhealthy as to yield sufficient nourishment to the *Ficus elastica* till it has become connected with the soil and established itself as an independent tree, and the "veritable forest of trunks" remains a thing to be wished for, but does not exist in nature.

As regards an entirely artificial rubber plantation, Mr. Jackson's description is perfect. In fact over acres of such plantations the roots of the trees, in some instances planted 100 feet apart, have not merely become interlaced but have amalgamated, and acres and acres may be said to live, so to say, on one great root.—*Indian Forester for October*.

PLANTING NOTES.

THE PAPAW JUICE, which is now quoted at 5s. per lb., is easily prepared. The unripe fruit has to be scarred or lined some $\frac{1}{4}$ in. deep, with a sharp knife daily, and the juice caught and dried upon sheets of glass, when it becomes at once a marketable commodity. The active principle, papaw is in much esteem as a medicinal agent. The *Chemist and Druggist* gives the following method of preparing it:—"The juice is pressed out of the fruit, clarified by filtration through a twill bag, and the ferment precipitated by alcohol. It is then dried, but is sometimes purified by treatment with water."—*Planting Opinion*.

THE OLDEST POPLAR IN FRANCE.—The citizens of Dijon, France, recently voted a sum of money for putting a railing round a tree standing within the city limits. The tree bears a label which informs the sight-seer that it is the oldest Poplar in France. The Town Council has a record tracing the history of the tree since the year 722 A.D. It is 122 ft. in height and in circumference.—*Scientific American*.

THE EXPORTS of Coal and Coke from India for the year ended 31st March, 1897—says the *Indian and Eastern Engineer*—amounted to 136,719 tons, the destinations of which were:—

Ceylon	93,635 tons.
Aden	16,775 "
Straits	14,532 "
Mauritius	7,757 "
Turkey in Asia..	2,550 "
Sumatra	1,300 "

and trifling quantities to the Persian Gulf and to Zanzibar.

CULTIVATION OF THE SOY BEAN.—Dr. W. G. King, of Calcutta, has requested certain officers in Vizagapatam, Bellary, and Saidapet to report upon the possibility of cultivating the "Soy bean," with a quantity of which he furnished them. The "Soy bean" is, he states, probably the most nutritious form of readily assimilable pulse at present known, and should it prove possible to introduce it widely in Madras, it would prove of great advantage in jail administration and also to the poorer classes generally.—*Pioneer*, Nov. 5.

GERMAN EAST AFRICA is politically and commercially the most important, as well as the largest, of the German possessions, but it is unfortunately also the most unhealthy, says a report in the *London Times*. "Not a foot of East Africa," according to Major von Wissman, "can be regarded as healthy." Of the produce of the plantations in the province of Tanga coffee pays best, but it has been attacked by a disease which is the most serious in that the destructive fungus is considered to be native to East Africa. Tobacco and cotton can be grown, but not, apparently, under remunerative conditions. Special attention is being paid to indiarubber and coconuts. Agricultural experiments are being made in other districts also, but no opinion can be yet expressed as to their success. Gold-bearing quartz has been discovered at Usambara, but of too poor a yield to repay mining. On the other hand, as rich deposit of hard coal has been found close to the water at the north end of Lake Nyasa. The only railway so far is the Usambara line, of which 40 kilometres were completed by January, 1896, but funds failed to extend it, and the company is chiefly occupied in maintaining and improving the existing section, over which one passenger train a week is conveyed. A grant of £15,000 has, however, been made for preliminary surveys of a line from Dar-es-Salam to Lakes Nanganyika and Victoria, the cost of which for the first section alone (258 kilometres out of 1,738) is estimated at £592,500, but its construction cannot be attempted without a financial guarantee, which the Government has not yet ventured to propose to the Imperial Diet. It is worth noting that the total trade of German East Africa in 1896 (R10,338,278) less than a quarter of the imports came from Germany and less than one-sixth of the exports went to Germany.

CRITICISM OF CEYLON COMPANIES.

We felt sure that, sooner or later, the famous *Investors' Review*, edited by A. J. Wilson, was likely to find a text in some one or other of our Ceylon Companies; and sure enough in the October number just to hand we find three pages devoted to "A Weak Tea Company"; while an editorial note discusses the Company identified with its Chairman Mr. James Sinclair in anything but favourable terms. We can do no more in this issue than quote:—

A WEAK TEA COMPANY.

It is not a sign of prosperity, we regret to say, to find a particular industry honoured by a company formed under the fostering care of Messrs. Antony Gibbs & Sons. Whether it be the high and lofty ideals of the bank parlour, or the innate "cussedness" of things in general, that are against the firm, it is a fact that hardly a venture brought out by it of late years has been a success. Yet the firm does not weary in well-doing, and despite the malevolent way in which the nitrate, gun-making, and brewing industries have foiled its efforts in the past, it is now giving the reflected glory of its financial aureole to the tea-growing industry, by standing sponsor to a tea-growing concern. This Company—the Tea Corporation Limited (Ceylon)—was brought out at the end of July with a capital of £181,000 divided into £65,000 of Five per Cent. Debenture Stock, £65,000 of Six per Cent. Preference Shares, and £51,000 of Ordinary Shares. The object of the Company was to buy up a number of tea-growing estates in Ceylon, with a total area of 7,033 acres, of which 3361 acres were under cultivation. The price to be paid for this property, after allowing £5 per acre for uncultivated land, worked out at about £45 per cultivated acre. It does not seem to be a high price, as Ceylon tea companies go, but this is perhaps the best that can be said about the issue, for the prospectus is drawing up on the free-handed system. A list of thirteen estates to be purchased is given, and it is set forth in big type that considerable economy will be effected by working them in one combination. But the prospectus rhetorician does not mention that four of these estates have for years back been worked as one company, that three others had been similarly handled, and that two more were one in all but name. As a fact, the London market knew these nine estates as three, and therefore the economy of combination had already been in force to a great extent. Then although the 3,211 acres under tea to be purchased was mature, except as to 282 acres, no record of past workings is set forth in the prospectus. Now, to have such a mature area implies that the estates must have been worked for a number of years; why, therefore, this mystery of silence?

Most probably the reason for this omission is the fact that no satisfactory statement of past profits could be drawn up. The estates in several cases are poor, four of them having formed the Lauderdale Tea Estates Company, which after having been in existence a good many years, paid, we believe, its first and only dividend of 2 per cent. last year; and two others to the Asiatic Produce Company, which has the still more unenviable record of never having paid any dividend. A number of the estates, including the Lauderdale group, have to our knowledge been offered about the City with a view to inclusion in a company, but no one who had a knowledge of the industry would take them over at the prices asked.

The only piece of information vouchsafed as to the past by the gracious sponsors is that the crop for the year ended 30th June last amounted to 1,060,463 lb. But while no information is afforded, there is a wealth of estimates, and by the dexterous use of this childish device, a visionary dividend of 10 per cent. on the Ordinary Shares is brought out. These estimates, by the bye, are made by Mr. F. Tatham, who is to be managing director in Ceylon, and who, therefore, must be considered not wholly unbiassed in his judgment. He

starts with the amazing surmise that in the current year the crop will be 1,250,000 lb., or just 189,537 lbs. more than in the preceding year. This is an increase 18 per cent., produced by an area that has less than 3 per cent. of tea shrubs only in partial bearing upon it. Why such an increase should be expected we fail to discover, except that it comes in hardy to swell the estimate of coming profit. Then this 1,250,000 lb. of tea is figured out to produce 6d per lb. *nett*, and from the gross revenue of £31,250 thus triumphantly reached, the deductions of working expenses and interest charges are made, so that it is all plain sailing. Now, the majority of the estates are situated in districts of Ceylon that produce a low-priced tea, and yet such a nett price would imply that the Company must dispose of its tea at an average gross price of at least 7d per lb., in order to cover the freight, landing, warehouse, and sale charges that go to make up the difference. In the most recent Mincing Lane sales the produce from six of these estates has been selling at 5½d per lb. gross; of one at 6½d per lb. gross; and of another at 7d per lb. gross, and only the produce of three of the estates has produced more than the indispensable 7d per lb. gross. Finally, the exchange for the purposes of the estimate was taken at 1s 2½d, yet the day the prospectus was issued the Indian exchange stood at 1s 3¾d, a difference of 1½ rupee, which would probably mean a loss to this Company of £1,800 per annum at least, and since then the quotation has been forced higher still.

Too hopeful an exchange is therefore assumed, the increased production seems to be taken at too high a figure, and the *nett* price to be obtained appears sanguine. What this combination of favourable estimates means can be discovered if we assume more moderate figures. Should the Company produce in the current year 1,100,000 lb., more than last year, a very fair increase on an acreage of this character, and if this crop yield 5½d. per lb. *nett*, which is by no means a low estimate, and if the exchange rules at 1s 3¼d—it is now 1s 4d—the Company would find its *nett* revenue amount only to £5,370 instead of the £12,970 set forth in the prospectus. Were such to be the case, and from the present condition of affairs our estimate seems more likely to be fulfilled than that of Mr. F. Tatham, the Tea Corporation would not be in a position to pay the full interest upon its Preference capital, to say nothing about a dividend on its Ordinary Shares. Of course we do not say that this will be the result of the first year's working, but if estimates can be varied so easily, no one can wonder that we prefer to have hard facts as to past working. The remainder of the prospectus is filled up with windy generalities about the enormous increase in the consumption of tea, and a statement of dividends paid by Ceylon tea companies, which is not entirely correct. We note, however, that the vendors give themselves the option of taking the whole £169,000 of the purchase price in cash, if the public be foolish enough to subscribe the whole of the capital. Therefore, although the Company possesses the benefit of a sou of the Governor of the Bank of England as director, and has a so other high-class banking connections upon its Board we should strongly dissuade the public from touching any part of its capital. It is companies such as these, and there are too many now being formed, that will bring disrepute upon the tea-growing community, which of late years has been rather free from wild-cat creations.

* * * * *
Now we come to the first of "Company Notes" as follows:—

Dimbula Valley (Ceylon) Tea Company.—In our article about Ceylon tea companies, we advised the public not to be sanguine about the future of some of the newer companies. This is one of the newer companies, and in reference to it we might even go a step further and say that we regard its future with extreme apprehension. Established in January 1896, its first report shows that with £150,000 of share

capital and £6250 of mortgages, the Company possessed 1441 acres of land under mature tea, and 444 acres under immature tea, so that the reserve land only amounted to the trifle of 206 acres. The capital cost was therefore over £100 per acre, and how this must handicap the concern can be imagined when it is stated that any company with a capital cost of over £50 per acre is considered highly valued, while most of the good companies have a capitalisation of between £19 and £40 per acre. To show how badly this Company shows up, we compare its figures with those of a few other companies on the same basis, as we did the companies in the article on Ceylon tea companies,

Companies.	Total land held.	Land under mature Tea.	Land under im-mature Tea.	Total Deben-tures and Share Capital.	Reserve and Amount forward	Capit. p. mature a. after deducting Res.	Aver. pr. realised for Tea.	Yield per acre.
	acr.	acr.	acr.	£	£	£	d.	lb.
Dimbula Valley	2091	1441	444	156,250	375	101	9 ³ / ₄	556
Edarapolla ..	894	471	129	22,000	295	39	6 ³ / ₄	640
Highland ..	702	545	41	32,000	404	55	9 ³ / ₄	357
Standard ..	3290	1519	761	60,000	9800	22	11 ³ / ₄	398

The Company has the benefit of a rather high yield per acre of tea, for which a good price is obtained, but this does not warrant such a high capital value per acre. The Board managed to bring out a trading profit of £14,596, and a nett profit of £13,375, but we should rather doubt their methods in arriving at this result, while nothing can be said about them, as no account of the working of the estates is rendered. By this means a dividend of 10 per cent. on the Ordinary Shares was distributed, but we feel sure that the heavy capital cost is bound to tell its tale in the future.

Two things puzzle us extremely here, namely, how Mr. Wilson makes out the Dimbula Valley tea area to stand so high as £101 an acre, and how the "Standard" can hold their fine properties so low as a cost of £22 capital per mature acre? Perhaps we may have corrections on both points.

PLANTING NOTES.

THE AFRICAN COFFEE COMPANY.—Mlangi Coffee Estates, Limited, was registered on Oct. 16th, with a capital, £50,000, in £1 shares to adopt an agreement with J. Crabb, and to plant, grow, manufacture and deal in coffee, cocoa, tobacco, sugar, maize, tea, etc. The subscribers are:—A. Eldridge, 32, Hamilton Bldgs, Gt. Eastern St. E. C., accountant; H. F. Garrett, 54, Gloucester St. Bloomsbury, W. C., gentlemen, J. B. Somerville, 48, Lincoln's Inn Fields, W. C. solicitor; A. P. Paine, 20, Essex St. Strand, W. C. solicitor; J. Crabb, 26, Wetherell Rd, N. E. gentleman; C. H. Chambers, Belle Vue, Swanley, Kent, clerk; and J. Edwards, Swan Grove, Cricklewood, N. W. gentlemen.

THE "INDIAN FORESTER."—A Monthly Magazine of Forestry, Agriculture, and Travel. Edited by J. W. Oliver, Conservator of Forests, and Director of the Forest School, Dehra Dûn. The following is the contents for No 10—October, 1897:—I.—Original Articles and Translations. India Rubber; Kumri Teak Plantation, by A. L. Lowrie; II.—Correspondence. The After-training of Coopers Hill Men. Letter from "Scrutator"; Gurnand's System. Letters from N. Hearle and "Kritik"; The Formation of Chlorophyll. Letters from J. L. MacCarthy O'Leary and A. W. Lushington; III.—Official Papers and Intelligence. An Enunciation of Forest Policy by the Madras Government; IV.—Reviews. Forestry in Jeypore State; Forest Administration in Bengal during 1895-96; V.—Extracts, Notes and Queries; VI.—Timber and Produce Trade; VIII.—Extracts from Official Gazettes.

CARDAMOM OIL.—The oils of different species of cardamoms described here have been distilled heretofore by us as well as by others. Their composition, however, has as yet not been ascertained; we therefore insert here a brief resumé of the results of our examination of these oils, abstracted from a report which will soon be published in some chemical periodical.—Schimmel & Co's. Report. [Then follows a learned analysis of oils from different species of cardamoms.—Ed. T.A.]

TEA CULTIVATION AT NEW CALEDONIA.—Efforts are being made to encourage the cultivation of the tea plant in New Caledonia. An exchange to hand by the steamer "Tanais" yesterday states that a quantity of tea seed was received by the Agricultural Union at Noumea by the mail steamer "Polynésien, and would be distributed among those desirous of attempting the culture of the plant. It is considered that the climate of New Caledonia is admirably suited to the growth of tea, and that if the matter were taken up energetically it would prove a source of wealth to the French colony, by reason of the enormous demand for tea in all parts of the world.—Planters Gazette, Oct. 1.

A NEW ROOF AND WALL COVERING FOR IRON AND WOODEN BUILDINGS IN TROPICAL COUNTRIES —is described in the latest *Indian and Eastern Engineer*. It is a new cement called "Tilestoneite" Cement, which is both heat-resisting, waterproof, and fireproof and consequently for hot countries is an invaluable adjunct to roofs, and outside walls, of iron and wooden buildings. In fact, wherever it is desirable to reduce the temperature as in bungalows, station-verandahs, barracks, stores, factories, laundries, creameries, etc., the use of this cement does away with the necessity for the expensive double roof sometimes put up for that purpose. Further, being completely waterproof, it is specially suitable for wooden structures, the use of which is restricted by the fact of their not being rainproof; and, of course, the cement can be applied to buildings covered with iron or felt? We read further:—

A considerable advantage claimed for this cement is that it will adhere to perpendicular walls, whether constructed of brick, wood, or corrugated iron; and this virtue still further prevents the absorption of heat from the sun's rays, thus reducing the temperature within. "Tilestoneite" Cement is non-inflammable, and completely protects iron buildings from the corroding effects of salt, spray, steam, or vapour; and as it contains no deleterious substance, water coming from it may, with safety, be used for drinking and domestic purposes. The cement is light-grey in colour—the best refractor—and is made of materials which are the best non-conductors of heat, and it gives a stone-like and finished appearance to any structure to which it may be applied. The cement is applied in a dry state, and all that is required to bring it into working condition is the addition of a little water, when it can be applied in layers, with a trowel or plasterer's float, no skilled labour being requisite. The manufacturers reckon that one ton of this cement will cover about 430 square feet of corrugated iron, 1½ inch thick and the cost per square foot, therefore, is very trifling. Compared with slates or tiles the saving is equal to 50 per cent in material, with the additional advantage that no skilled labour is required. For wooden surfaces an inch being too sufficient thickness, a ton will cover 573 square feet, at a cost of 2d per square foot; whereas one ton of slates or tiles will cover only 220 square feet, and will cost 4½d per square foot. One of the best testimonials to the merits of this cement is the fact that it is supplied to the British Secretary of State for India, the Crown Agents for the Colonies, and the Agents General for the Cape of Good Hope, and Western Australia, for use on Government buildings.

The sooner the manufacturers get agents in Ceylon to advertise and supply "Tilestoneite," the better!

To the Editor.

COFFEE PLANTING IN NYASSALAND :
A REPORT BY A RESPONSIBLE
PLANTER.

Chipande Estate, Blantyre, B.C.A.,

Aug. 25, 1897.

DEAR SIR,—A contribution in your June number, headed "Planting Prospects in British Central Africa," by a gentleman, Mr. ———, gives most misleading statements; hence permit me to correct his truthless allegations. Although I have lived a number of years in this country, I never heard of this man who tries to pose as one who came to prospect for land suitable for coffee plantations. Making enquiries about this coffee expert, I found out that he walked here from Mashonaland, and was glad to accept a position as barman, which he gave up with the intention of prospecting for gold in the Northern parts, and joining company with a trader, who allowed him to do so. When returning, without success, he tried to obtain a position with the Chartered Company, but being unsuccessful, he disappeared. It is only with a certain amount of reluctance that I write to correct statements of this description, but as a resident in this country I do not like to see injustice done to it by false and untrustworthy reports.

Coffee has not been a failure, and although in the beginning it did not always prove successful, for want of capital and knowledge, it has now established itself as a well-paying industry. It is distinctly untrue that everybody here is trying to form companies.

Transport, considering that we live in the interior of B. C. A. is cheap, costing only £3 per ton for coffee from Katungas to the sea coast. The average cost of land carriage to this part (according to distances) from 10s to 60s per ton. The average rate of wages is only 3s a month, which includes food pay. Labour is inexhaustible, and a number at certain times of the year must return home for want of finding work. If some planters cannot get sufficient labour in the wet season, they are themselves to blame, as they do not provide sufficient food supplies and the men want food to live. My labour, and the same of the majority of planters costs no commission for obtaining, and only in some instances are agents employed.

The soil is not inferior to that of any other country, where coffee is grown. It varies in quality, and large blocks of good uncultivated land can be bought at low prices.

Like in any other tropical country a man must live a moderate life, and by observing this condition, he need not fear to live here.

The Tanjanyiki plateau, to which Mr. ——— refers, as being unfit for white settlers, is a beautiful part of Central Africa and will soon be developed, and settle a large white population, in spite of that gentleman's wholesale adverse statements. The heat is not great, we are about 3,000 feet above the sea level, and if heat should inconvenience me I would sooner live here, than in Colombo.

We have plenty of water in this country, but no large river exists in Blantyre, as is stated by Mr. ———.

Coffee disease in our country is also a new discovery of his, and this eloquent gentleman, surely knowing this, wasted his time prospecting for coffee land. I have no doubt that any reader will at once see what harm men of this type might do, if such statements are not corrected. Not wishing to encroach on your space any more I conclude with the offer to willingly give my report and information to any enquiries made to me.

Yours truly,

S. ISRAEL,

Planter, Chipande Estate, and Manager of Messrs. Buchanan Bros.' Estates, Michiru and Zomba.

SIROCCO TEA MACHINERY.

"Sirocco" Engineering Works, Belfast, Oct. 6.

DEAR SIR,—As you have on many occasions been kind enough to make favourable reference to my tea machinery in your columns, and to publish descriptive articles regarding some of the new machines which I have placed upon the market from time to time during the past few years, I take the liberty of forwarding to you by this mail, under separate cover, a copy of my new catalogue of Sirocco Tea Machinery, and should feel very much gratified if you could see your way to notice same in your columns, as I have no doubt such an article would be read with interest by your planter readers.

This catalogue is very much more complete than any I have yet issued, and is the only complete catalogue of tea machinery that has ever been published—in fact no other firm manufactures machinery for more than two or three of the processes through which the leaf passes, whereas, as you will see from the introductory remarks in my catalogue, I can lay claim to be the "first who can now supply tea factories with an entirely complete outfit of mechanical appliances for each and every process in the manufacture of tea, from the time the leaf is brought into the factory up to its being sent off as finished tea in packed chests," and which wide claim is supported by the descriptions and illustrations subsequently given in the catalogue of the various machines that I manufacture. Amongst these are included one or two new machines which have yet to make their reputation in practical employment on the tea estates, though I expect they will do so in course, quite as much as my new roller (which was first brought under public notice in my catalogue of last year) has done already, and so well have the rollers been received by planters, more particularly in Ceylon—where they were first introduced—that many orders have already come in as a consequence of the working of the first machines sent out; and planters seem to appreciate the fact that this machine is an entirely new departure, both in construction and method of applying pressure to the leaf (which you will see for yourself, if you glance through the descriptive part relating to the roller), while at the same time it has the still further advantage in their eyes, of being considerably cheaper in price than other rolling machines of equal capacity.

The view of my works is different from any that has appeared in my previous catalogues, on account of its being taken from the reverse end of the premises to what my previous views were, namely from the end facing the river Lagan. The view of Belfast seen beyond the Works, is absolutely correct, and any planter knowing the town here would recognise the principal local features shown in the illustration. I have put the names of each of the "shops" on the tops of the roofs in these drawings, to indicate them for the benefit of planters who have never been my works, and don't know anything about their extent.

Then as you will see, I have shown photographs of the heads of my official staff at home and abroad, and I have also shown photos of the foremen of each of the various departments. The insertion of these I thought was desirable, because it has often been told me that many planters abroad, know-

ing that I was myself once a planter like themselves out there, fancy that my place is likely a kind of amateur engineer's place, and not got up on the lines, or to anything like the size of old-established premises, whereas in reality I think they would be larger than the average of engineering concerns over the country, and their equipment is complete and up-to-date in every respect. I thought therefore that if I would let my constituents see that it is not altogether with me personally that they are dealing, but, that I have a large and intelligent-looking staff in charge of the official and management part of the business, as well as an intelligent lot of foremen in the various departments of the works, it would likely produce in their minds a feeling of greater confidence as to the probability of my turning out good machines, than if they thought the whole thing was a kind of amateur place, without much in the way of a staff of foremen and officials, such as, I am glad to say, I am able to show; besides which, Ceylon and Indian planters will be interested in the photos of the men with whom they have to deal in connection with my depots in Colombo and Calcutta respectively.

In the introductory remarks that I make, following the photographs, I have confined myself to a few important and particular statements, which I hope you will find time to look over; and a peculiarity in the wording of the catalogue, to which I would like to call your attention, is that a portion of the matter is printed in heavy type, and if you simply glance down any of the pages, reading only the heavy type, you will find that it reads consecutively, and forms a condensed synopsis of the leading features of the body of the descriptive matter.

The first machine shown in the catalogue, which refers to the "conveying" of leaf, has of course not been worked on any tea estates yet, as it has only been employed in Messrs. Gallaher's enormous factory in Belfast for conveying tobacco leaf, but, as you will see mentioned in the descriptive matter, tobacco leaf being not only very much more delicate but a great deal larger and more difficult to deal with than tea leaf, when the apparatus has been found very suitable for tobacco, it ought to be still more suitable for tea.

Then as regards the withering machine, which comes next, the difficulty of introducing such a new and "revolutionising" process is so great, that it has involved a large number of experiments, and I am not really pushing for orders for the machine yet, because the experiments have not been carried out so sufficiently far to satisfy me that the best possible results have yet been obtained with the machine, but notwithstanding this, the results show already that I can get quite as good a quality of tea as that made in the ordinary way, but I am still in hopes of being able to produce a *higher class quality* with this machine, and until my experiments are absolutely completed in a practical way—and which are being carried out under the supervision of my own engineers, I am not looking for orders as yet, but think it well to include the machine in the catalogue now, as its being shown will gradually get planters familiarised with the idea of effecting the withering of the leaf by machinery, which at present would be too much in the nature of a revolution, for them to think seriously of adopting, until their prejudice and conservatism is overcome as regards the old routine of manufacture, and they are forced in their own interests to adopt the latest and most up-to-date systems, when such are shown to produce as good, if not a better quality of tea than ordinary manufacture.

The other machinery illustrated and described in the catalogue is already well-known and in general use on the tea estates, but amongst the new improvements which are being applied to my Drying machines, you will see particular reference made to the new Multitubular Air-heater, of same type as applied in the large "Auto-Sirocco", which has proved such a successful machine, not only as regards the amount

of work of which it is capable, but also as regards the quality of the tea which it turns out, the improvement in which is attributable to the system of drying applied in the machine. This new Multitubular Air-heater is applicable, in reduced sizes—large and small Dwindrafts, also to 16 and 20-tray Uprdrafts, and its employment is strongly recommended as it is more economical in fuel, and its air heating capacity is about 30 per cent. greater than that of the corresponding size of the vertical-flue type, which important advantages more than counterbalance the relatively higher price of the Multitubular Heater.

No doubt you will find other features of interest in the new catalogue, to which I needed not specially call your attention, and hoping that you can see your way to give a notice of same in your columns, and thanking you in anticipation.—I am, dear sirs, yours faithfully,

S. C. DAVIDSON.

[The catalogue was noticed in our last issue.—Ed. T.A.]

LOCUST PESTS IN CEYLON.

DEAR SIR,—In your notes on this subject, in your last issue, you remark that, so far as existing records go, no extensive mischief has been done by locusts in Ceylon. With the columns of *Tropical Agriculturist* open to receive any information on planting subjects, this ought not to be the case. As a matter of fact, these insects have at various times developed in considerable numbers, and as they have apparently no known enemy except, perhaps, sudden changes of weather, it is necessary for planters in every district to keep a sharp look-out for them. I remember finding a single specimen in the Kotmale patauas some seventeen years ago, and subsequently on several occasions have come across whole broods of them in the low-country. In one instance they were found in some chena on the borders of a young cacao estate: the vegetation was stripped absolutely bare of foliage. I am not sure whether any *lantana* was attacked, but guava trees were stripped to the buds, and wild plantains had only their mid-ribs left. I killed nearly five hundred locusts: a few escaped. Insects that will devour either of these plants are not likely to have any objection to feeding on tea or cacao leaves whenever there is a scarcity of the food on which their parent brood subsisted.

About two years ago, on an estate not far from the one just referred to, the dadap trees over several acres were almost denuded of foliage: the sound caused by the falling chips of leaves and the locusts' droppings on the cacao trees beneath was like a heavy shower of rain. I was told that an adjoining estate was affected in the same way. I have not heard if the subsequent brood was destroyed or not.

So far as I have observed, the insects usually breed in illuk grass and the stunted vegetation of abandoned coffee fields. To search for their eggs in such places would be practically impossible, but the destruction of the young locusts in the grass, before their wings develop, is an easy matter. If the grass is dry, one can set fire to it, but if this remedy cannot be applied, the insects can be caught in nets or Hessian bags and crushed on the nearest open space.

As the locusts when full-grown exude, when disturbed, an acrid yellow froth, birds and lizards will not eat them; the crow perhaps might be an exception. The burning off of chena and illuk grass along estate boundaries would at first sight appear to be a good preventive measure: on the other hand these are the most convenient places in which to search for the insects when laying their eggs or for the newly hatched broods.

As verbal descriptions of insects would convey little information to the average planter, and as I understand the Director of the Colombo Museum has never sufficient stocks of these or any other insect pests to supply specimens for general distribution, the Government should circulate coloured lithographs of any insect pest which appears to be increasing.—Yours faithfully,

B. E.

[We are obliged to our correspondent for his interesting information: we must await our 'topical index' to be able to say readily what is in the 16 volumes of the *T.A.* Nietner takes no notice of locusts.—ED. *T.A.*]

RAMIE CULTIVATION:—FACTS AND FIGURES.

Dessford, 16th Oct.

SIR,—In the *Observer* of the 12th instant, (see page 330) there was a long and interesting article on the prospects of Ramie cultivation in Perak.

I quite agree with the writer that the exaggerated reports issued by Companies and individuals with a patent process or machinery for sale, have done much to retard progress in this product, so far as Ceylon is concerned.

In comparing the three estimates, Mr. Wray shows a loss on cultivating "Ribbons," Mr. E. Mathieu a profit of dollars 162.30 per acre for "China grass," and Mr. MacDonald a profit up to £50 per acre for "Filsasse." These estimates are based, apparently, on experimental plots in various parts of the Straits and must be considered far from final; still, surely there is room for encouragement to persevere with the cultivation, if only experimentally.

The late local syndicate gave as their reason for ceasing operations, that the product was so hedged about with patents that they were afraid if they grew it on a large scale, prices would be such as to preclude all chance of profit. A few years ago "China grass" was £22 per ton, whereas now it is about £35 per ton, and the annual consumption has reached over 2,000 tons spread over the Continent, England and America. This hardly looks as if the price was being driven down by holders of patents.

There has been an endeavour to interest planters to grow "Ribbons," but seeing "Ribbons" lose 60 per cent in treatment, whereas "China grass" loses only 30 per cent, it will be seen that in this country of high freights, the former has not much chance, except when the cultivation is in an experimental stage.

It must be remembered that in dealing with a crop of 20 tons of green stems per acre that 80 per cent is water and another 15 or 16 per cent is woody matter and leaves, which can be returned to the soil, leaving only from 4 to 5 per cent or 16 to 20 cwt. per acre taken out of the ground.

Let any planter with suitable land try an acre or two experimentally, and make his crop into "Ribbons" which requires no machinery. He will then be able to see if there is sufficient encouragement to go into the matter on a larger scale and lay down "Plant" for either "China grass" or "Filsasse."

Finally, to quote Dr. Morris, of Kew, in 1893, the total value of fibrous material imported into the United Kingdom was £50,002,244, of which £5,357,968 was received from British possessions and £44,644,279 from foreign countries. These figures speak for themselves and surely here is a possible chance of a remunerative low-country cultivation instead of increasing our acreage in tea.—Yours faithfully,

ED. ROSLING.

Colombo, Oct. 19.

SIR,—I have read with much interest Mr. Rosling's letter in your impression of the 18th. It is quite refreshing to read a letter on this subject from one who undoubtedly understands the matter and looks at it from a practical point of view.

Mr. Rosling, I am glad to see, is backing up the advice I have offered to such of the planters as I

have had the pleasure of meeting over here—that is to *experiment*. I have suggested two acres as a suitable area to put under cultivation as this will enable them to check what the *Observer* calls my exaggerated figures. If they find in Ceylon that they cannot get more than 20 tons of stems free from leaves an acre, I should advise them to stick to their tea as 20 tons per acre will not pay. Calculating the filasse at 2½ per cent, it will only produce 11,000 lb. which at 4½d per lb. would fetch about £20. This £20 has to bear the whole of the expense of cultivation, treatment, freight, etc., etc., and would leave the planter a mere pittance. Get 40 tons per acre and Ramie begins to pay well, but nothing under 30 tons will pay.

Another thing for the planters to bear in mind is that the only way to make Ramie pay is to decorticate and degum on the spot and send the resulting filasse to London. When once this is done the days of ribbons and chena grass are numbered. Who will pay £35 per ton for chena grass when it takes three tons to make two of filasse. Hence each ton of filasse costs £42 10s. to which you have to add the cost of steam, English labour, rent, taxes and chemicals. British manufacturers will readily welcome Ramie filasse, and it will soon create such a demand as to increase its price, and for a reasonable crop £42 per ton pays well, but there is no reason why £60 per ton should not be obtained for small parcels of a few tons.

My firm do not sell our patented machines. We either supply them at cost price or supply working drawings, from which planters can have their own plant erected by any local firm. It may, however, pay them to have the machinery through us as our manufacturers have the patterns, and they would, of course, get the benefit of this, added to the fact that we should test any machines before leaving. We look to our profit when the planter makes his and not before. We then take 25 per cent. of the *net* profits, and undertake the sale of the filasse which, of course, it is our interest to see fetch the highest price and keep the market up.

I am writing a handbook to planters, with full instructions for planting and treating the fibre, which I shall be happy to send to your readers if they will apply to the office of my firm, 39, Victoria Street, Westminster, London, S. W.—I am, etc.,

J. M. MACDONALD.

DEAR SIR,—Don't you think, Mr. Editor, you have misapprehended Mr. MacDonald's figures on Ramie somewhat, when you express a doubt "whether 20, 13, or even 10 tons of yield of fibre per acre, per annum will ever be gathered continuously for any number of years over an appreciable area in Ceylon?" The crop which Mr. MacDonald estimates, on the basis of experience at the Straits, is "78 tons of stems per acre per annum." The stems include leaf, stick and fibre—as they do in Cinchona and Cinnamon, the bark, leaf and wood; and he proposes returning to the soil all that can be returned, save the fibre. Now, the fibre he calculates at only "2½ to 3 per cent of the crop." It would, perhaps, be more correct to say that the crop is 2½ to 3 per cent of the cuttings, as what is thrown away, because useless, can scarcely be called crop! Well, 2½ per cent of 80 tons will be only 2 tons; and even that at £42 per ton ought to satisfy the average investor, assuming that the fibre can be laid down in Dundee at 1½d a lb. Of course, I venture no opinion on the figures, or on the investment. I only draw attention to the confusion that has evidently arisen from speaking of the waste products as crop, and to the difference between stem and fibre.—Yours truly,

PLANTER.

[We are under no misapprehension as to Mr. MacDonald's figures; but doubt their realisation.]

Ceylon, as indeed does Mr. MacDonald himself. Can our correspondent tell us as a matter of curiosity what the gross weight of an average cinnamon crop—sticks and all—or of coconuts, is, per acre? We shewed the maximum for moist tea leaf was about 2 tons; while average coffee—in its cherry form—may have given 3 to 4 tons per acre?—Ed. T.A.]

DEAR SIR,—Let me premise at the outset that I am a believer in Ramie as a paying crop, provided, of course, that the necessary machinery for treating the fibre is set up in Ceylon, and that the flasse will fetch £42 per ton. But at the same time I am not a believer in Mr. MacDonald's figures. Not that I mean for a moment to insinuate that they are cooked! but that they are not quite consistent, and are therefore misleading in a manner that Mr. MacDonald himself may not suspect. While he was here he pretty well bewildered ordinary mortals, and at least one editor, with the great mass of figures he thrust upon them. The "Examiner" in its leader of the 25th instant says: "From trials made it has been ascertained that fifteen of these stems will weigh four ounces." The statement is no the face of it absurd, nor could Mr. MacDonald be credited with saying it. What he did say was that the mean of fifteen stems small and large weighed 4.8 oz.

Now that Mr. Macdonald has left us we can examine his dazzling figures at leisure. The "Examiner" again in its editorial states,—"If therefore the cuttings were put at 18 in. apart they would give, he says, eight to the square yard, or 38,720 to the acre." Did Mr. MacDonald really say so, or was the "Examiner" misquoting again? On turning to the *Observer's* interview" of Oct. 19th, it was found that Mr. MacDonald had actually put it so. Here is a sum in arithmetic: What number of plants will there be (1) in a square yard, and (2), in an acre of land, if the plants were put 18 in. by 8 in.? Work it out for yourselves and do not trust to any one's figures. And what do you get? Four plants per square yard, and 19,360 per acre,—just half Mr. MacDonald's figures, which would represent the number when the plants were put 6 in.

With 19,360 plants per acre, the weight of the crop of stems from an acre (at the rate of three stems per tree) will of course be 39 tons and not 78 tons, Now Mr. MacDonald when he put his crop of sticks per acre per annum at 78 tons, said that 1½ tons of flasse would be a safe estimate; we shall now have to divide this by two, whereupon the weight of flasse is reduced to ¾ ton. This at £42 per ton in England would realize £31 10s.

Now what is the cost of producing a ton of flasse? Mr. MacDonald tells us that it can be grown, treed, baled, imported into England, with freight and all charges paid, including brokerage, at 1½d per lb. At this rate the cost of ¾ ton would be £10 10s; and the profit per acre would be represented by the difference between £31 10s and £10 10s, or £21. "From these profits," Mr. MacDonald candidly allows, "the patentee's royalty of 25 per cent will have to be deducted." And this will bring down the net profit per acre to £15 15s,—rather a come-down from £50 per acre!

But there are some who may point to the elaborate calculation in the *Observer* of the 12th Oct., (see page 352 of November issue) where Mr. MacDonald by giving all the working details makes out the profit of nearly £50 per acre, and may ask how such a calculation can be at fault. Well, it will be found that according to it, the cost of producing one lb. of flasse is as nearly as possible 1.14d only. Now if the price obtainable for 1 lb. (at the rate of £42 per ton) is 4½d, this would leave a profit of 3.37d on a lb. or £32 on a ton. But Mr. MacDonald elsewhere tells us that ramie costs 1½d per lb. delivered in England. If we take the latter figure, the profit on a lb. will be reduced to

3.1 per lb. or £23 per ton, which makes a considerable difference on a thousand or so of tons! Now, which should we take of the two figures given for the cost of 1 lb. of flasse? Clearly 1½d as this represents the cost per lb. laid down in England where the £42 per ton, or 4½d per lb. is to be got for it. So that we must decide to accept a profit of £28 on a ton of flasse. Now, what is the amount of produce as flasse per acre? That is the point to be settled. If we say with Mr. MacDonald 1½ ton, then we must suppose that the crop of sticks from which this must be got was 78 tons and that the land carried 38,720 plants per acre, or eight per square yard. We saw that with eight plants to the square yard the plants must be put down 6 in. by 6 in., but if on the other hand the plants were to be put in 18 in. by 18 in., when there cannot be more than four plants per square yard or 19,360 per acre, and therefore, the weight of flasse would by the same calculation be reduced to ¾ ton per acre. The profits on an acre would thus be three-fourths of the profits on a ton, and that is £21. Taking 25 per cent off, this for patentee's royalty, we again get £15 15s profit per acre, and not £50!

Let me, however, repeat here what I said at the outset of this letter than I am a believer in Ramie, and that what planters must now do is to have experimental plots of an acre or two and satisf, themselves as to the suitability of soil and locality and the probable crops to be expected per acre.—Yours truly,

[But "D." must remember the conditions laid down by Mr. MacDonald for successful growth, in which we quite agree,—namely, equable temperature, good soil, and well-distributed rainfall; and so we have pointed to the South of Colombo, and especially the Galle district, as best for an experiment. The Udagama Company should certainly try one. Particulars given of an experiment by Messrs. Clarke, Young & Co., to a contemporary are as follows:— "Two and three-quarter acres of land have been planted up with the new product (obtained from Calcutta), and they can supply 10,000 cuttings at once, and more in a month or two. Four crops a year, he said, may be safely counted on as far as his experience goes. Mr. Young took up the idea some time ago on hearing of the offers made for ramie by Capt. A. Whitley, and he has already sold several lots at good prices. From what he tells us, it is evident there is a good deal more rhea in Ceylon now than most people are aware of. Not only is it growing in Kurunegala and Ratnapura; but the plant is thriving in Colombo at no greater distance than the Cinnamon Gardens; while Mr. Young informs us also that they are going in for it pretty extensively on the Pallagama Grant Association's land."

Ratnapura with its abundance of rain and heat ought to be a good district for ramie.—Ed. T.A.]

Colombo, Nov. 1.

DEAR SIR,—Your editorial comment on my letter, (see above) is to the effect that it would be quite possible to grow ramie successfully in Ceylon, and in that opinion I am at one with you. Indeed, I stated in the letter referred to above, that I was a believer in ramie as a paying crop. But the purport of my communication was to show that the calculation, according to which eight trees planted 18" by 18" are made to occupy a square yard, was wrong; ergo, the results based on such a calculation—viz., that 78 tons in sticks and 50 pounds in money would be got per acre—cannot be accepted. Like the estimable firm named in your quotation from a contemporary, I also grew ramie experimentally in the Cinnamon Gardens from plants imported from Calcutta, and can also supply 10,000 cuttings. But then there are others also growing ramie in Colombo—and a great many doing so outside Colombo. I doubt, however, if any

of us will, in spite of equable temperature, good soil and well-distributed rainfall, succeed in getting 78 tons per acre—which Mr. MacDonald makes out, according to his occult system of arithmetic, is a fair yield.

I see that the old word *rhea* is used in your extract. It is better that we should now drop it and stick to *ramie* as the name of the plant we are talking about. At one time *rhea* and *ramie* were considered to be a distinction without a difference, but that is not so now, and the words should not be confounded.—Yours truly, D.

Colombo Oct. 30.

DEAR SIR,—In a letter written by the Managing Director (Mr. MacDonald?) of the Boyle Fibre Syndicate to the Secretary to the Queensland Agent-General the following passage occurs: "If a guarantee could be given that 500 acres would be put down under cultivation and the product supplied to the mill, my company would be disposed to put up the mill, and the required machinery, and pay the farmers at the rate of 2d per lb. for every lb. of white degummed filasse produced from the stems supplied by them, or so much per ton for the stems supplied after. We have tested the amount of fibre produced, which would be about 4 per cent of the weight of the green stems."

It is a pity Mr. MacDonald did not volunteer to make similar arrangements in Ceylon, only offering something more than 2d per lb! In the above extract the fibre is said to be about 4 per cent. of the weight of the green stems. We have a recollection that Mr. MacDonald put down the percentage as between 2 and 3. Which is it? We want something definite to go upon.—Yours truly, D.

3rd Nov. 1897.

DEAR SIR,—Your correspondent "D," has very clearly exposed the simple error made by Mr. MacDonald in his estimates. The latter has taken a square yard, on paper, and planted it up at eighteen inches apart, quite forgetting that the plants on its boundaries would require a share of the soil in the adjoining square yards, and in his estimate of plants per acre he has further allowed for 10 vacancies caused by rocks, tree-stumps or drains. But there are other points on which information of a practical nature is desirable.

To begin with, the expert allows for roads and tramways three hundred acres in a twelve hundred acre block. Even if this large area is necessary for the regular and rapid collection and transport of crop, it is doubtful whether sufficient allowance has been made for the maintenance of three hundred acres of roads, especially as regards their weeding and drainage.

As he allows abns in Ceylon six months, instead of three, for the stems to mature after the cuttings are planted: no details, however, are given of the cost of the period which usually elapses before planting can be commenced. And there is apparently some confusion as regards the yield. If, just for the sake of argument, we take Mr. MacDonald's figures, at 78 tons of stems per acre per annum, we have, he tells us, to make each cooly cut and deliver to the tram lines six cwts. of stems (from two acres) for a day's work, at intervals of six weeks. But three cwts. per acre multiplied by eight cuttings per annum gives only 24 cwts. Even in an "equable climate," there would evidently be a serious shortage, and the cooly would have to find more stems than the expert reckoned, and telephone to the mills for more tram cars.

Next as regards the cultivation. We are not told whether Mr. MacDonald has ever grown *Ramie* himself on any large scale: apparently not. As one who has cultivated it, though not on a commercial scale,

so long as ten years ago, I may, perhaps, be allowed to suggest to the expert that such close planting as he proposes, 18 inches, even though it only gives a paltry 19,360 plants per acre, instead of double, that number, would most probably only lead to rapid deterioration. The advantages he claims are, of course, delightful to contemplate: (1) no weeding necessary after the plants are three feet high, let us say after the first two months: (2) the production of stems so extra long and free from knots that the market value could not possibly fall below £42 per ton, though, of course, buyers might gladly pay more. I do not claim to have ever seen even one acre of *Rhea* growing wild, but I very greatly doubt if it is to be found anywhere growing naturally as closely as the expert proposes to grow it. My plants were grown three feet apart: I supposed when planting them they would require air, sunlight and soil. Apparently my impression was correct: they grew very luxuriantly and the roots nearly met after six months. Mr. MacDonald evidently proposes to have no cultivation whatever: the cuttings have merely to be planted and then the climate and the cooly (nature and art) do the rest.

After this captious criticism, it will probably surprise you, Mr. Editor, to learn that, like your correspondent "D," I am also a believer in *Ramie* cultivation. But I should prefer to see *Rhea* grown as a subsidiary crop, or at any rate combined with some other product, and I should certainly prefer to buy decorticating machinery outright rather than pay away twenty-five per cent of my profits to any inventor. I raise no objection to the price quoted, £42 per ton, though, as Mr. MacDonald's figures of crop have had to be reduced by half, the price might fairly be increased. The sample which I sent home in 1887 was, of course, prepared by hand, and was valued at rather less than £40.

I should deprecate planting any closer than three feet. Though this would still further reduce the number of plants to 4,840 per acre, I should be able to obtain a better quality of fibre, not only because the stems would be grown more naturally and would have the advantage of air and sunlight, but because I should have space (which the expert would not) for working the soil between the rows and returning to it all the waste foliage and stems. And I do not think that by this system of cultivation my weeding would be expensive. I make no stipulation for an equable climate: we must forego that in Ceylon. But I venture to suggest that *Rhea* planted at this distance would yield per acre quite as good returns as plants treated on the wild kitchen-garden system which Mr. MacDonald has so strenuously advocated.—Yours faithfully,

B. E.

PLANTING NOTES FROM SOUTHERN INDIA:

RAMIE CULTIVATION, SHADE TREES, AND COFFEE, &C.

Oct. 28.

DEAR SIR,—I have carefully perused your notes and the writings of various Planters on the cultivation of the *Ramie* plant, but failed to discover that any one has reaped a profitable crop. More than 12 years ago I experimented with this plant, growing about $\frac{1}{4}$ acre in a ravine with good soil, but only managed two good cuttings annually and the fibre I used for general use on the estate.

I have it again here in a ravine, but so far have not given it any attention. I have seen its cultivation in Tinnevely district on the Parapet property. If it is to be cultivated to give a return, it must be grown on good flat land, capable of being planted and irrigated and also matured. Padi field land is suitable.

I suppose you receive that weekly Journal, "Planting Opinion" I occasionally have a look at it and observe it makes copious notes from the *Tropical Agriculturist*—it is a miserably copy,

ducted paper and the editor appears to have no knowledge of the subjects he writes upon and his "General Notes and Articles" are most inaccurate. The chief subject in his paper for the three months is *Erythrina lithosperma*. In the issue of 16th instant we are told that *E. lithosperma* is good firewood. No one with any experience of timber would ever make such a statement, the wood is utterly worthless for such a purpose, only spongy tissue. In the last number, 23rd instant, it is stated that the manager Ariendran, Shencottah, is the only person that can supply this variety of *Erythrina*: "that is a tall one!" Did he not bring the seed from Ceylon? Seventeen years or more, was the first of this variety introduced into Ceylon from Java, as a shade tree for Cocoa—the old *E. Indica* has been in the island for many years. Tons of cuttings and lb. of seed of *E. lithosperma* can be procured in Ceylon and also in Southern India. It is recommended as a "wind break;" that is not the experience of those who have planted it. It is a surface feeder, branches very brittle and easily blown over. The tree is a good temporary shade and for such a purpose it was planted in Java, Ceylon, Straits Settlements, Southern India and elsewhere. Now Mr. Nelson informs us, that, "old half abandoned coffee" has revived and become full of fruit and vigour under shade of *E. lithosperma*. We all ask where? I have Arabian and Liberian coffee growing with *E. L.* and cannot say that it is any better than the fields with *Grevilleas*, *Albizias* and other trees. Let cocoa growers look round and say if their trees are superior under its shade. Under thick shade of *E. L.* our Liberian coffee trees bear very sparingly. The best crops of coffee I have seen were grown under shade of *Ficus Glomerata*, *Albizia lebbek* and *stipulata*, and *Pithecolobium Saman*.

Was there ever any district in Southern India where the Arabian coffee trees produced such stems as was found in Matale, Rangala, Pussellawa, Uda-pussellawa and Badulla. I think not. Coffee is doomed in Southern India and no system of manuring will ever save it. This year it has had a most virulent dose of leaf disease. To satisfy my curiosity as to the condition of the roots of some of the severely attacked trees I had the roots of a few trees exposed and examined and found them to be in a very healthy condition.

Let Mr. Nelson and others who write extensively on scientific manuring, discover an antidote for the cure of leaf disease, and I am sure their brother planters will gladly erect a "statue" to their honour and glory—Mr. Nelson is great on green manuring, as he calls it, how long after application was the humus in a state for plant food? Practical Agriculturists and Horticulturists, those who go in for high cultivation, generally apply manures that will give the best returns in the shortest periods. Most naturalists know that plants are most susceptible of the food their roots consume and few roots will penetrate into a decomposing mass of vegetable matter. Tea can't go on for ever, and will have its time as coffee and all other eastern commercial products have passed their course of existence. We must make the most of it while it is in a vigorous state and reap the reward. Cinchona will yet give handsome returns to those in new countries who can cultivate it at suitable devotions. When we are increasing our products, some should try, "Patchouli, Pojasteman patchouli" it is a most profitable cultivation, being a valuable perfume, leaves and flowers containing an essential oil.

ARBORISTS.

RAMIE CULTIVATION, SHADE TREES, &c.

Nov. 4.

DEAR SIR,—Your correspondent, "Arborist," should be able to give us some useful information as to the yield of ramie fibre. He says he got only two good cuttings of stems from his plants annually: what was the actual yield from his quarter acre? I think your correspondent is wrong in supposing that paddy

fields are suitable for the cultivation: if thoroughly drained, of course they are, like any other flat land, but the ramie plant belongs to a family which is not aquatic.

With regard to "Arborist's" remarks on shade trees and his criticism of the Nilgiri journal, *Planting Opinion*, it is not possible, without perusing the whole of the articles he refers to, to say whether the Editor's views are right or wrong. Your correspondent in an airy way condemns the entire contents of three months' weekly issues, while admitting that he only occasionally has a look at the paper. He says the journal is "miserably conducted," but as the Editor "makes copious notes from the *Tropical Agriculturist*," there is hope for him yet. Personally, I may say that I have heard several Ceylon planters say they prefer the former paper as being lighter reading and less bulky than the "*T.A.*": there is probably room in the East for the circulation of both.

"Arborist" flatly contradicts the Editor's opinion that the dadap tree (*Erythrina lithosperma*) is useful for firewood. I have heard of one cacao estate in Ceylon on which the coolies use no other wood for fuel, and know of many others on which it has been used for years.

Your correspondent is in error as to the tree having been introduced from Java to Ceylon. The first seed was obtained from Assam, in 1857, with the object of supplying what was then thought to be of more importance than firewood, viz., charcoal for use in tea-house *chalas*, and cuttings from the first plants were distributed to the Royal Botanic Gardens and gradually to all the coffee districts, beginning with Pussellawa and Dikoya.

As regards the benefit to be derived from planting dadap in poor coffee, I am able from experience to confirm the opinion expressed by Mr. Nelson in the Nilgiri journal. No one has ever supposed, except perhaps your correspondent, that the dadap, or any other shade tree, was a cure for leaf-disease in coffee; but its shade is distinctly beneficial, and its roots going down to a great depth, open up and improve the soil wonderfully. I quite agree with "Arborist" that *Albizia*, *Grevillea* and *Ficus glomerata* are also useful. As to *Pithecolobium Saman* it is extremely brittle, and when a few years old is one of the worst surface feeders known.

The last part of "Arborist" letter seems to indicate that he belongs to that class of planters which, for want of a better term, must be classed as "sweaters." Blindfolded he runs afloat at green manuring, on the ground that "Practical Agriculturists and Horticulturists, those who go in for high cultivation, generally apply manures that will give the best returns in the shortest periods. Most naturalists (*sic*) know that plants are most susceptible of the food their roots consume, and few roots will penetrate into a decomposing mass of vegetable matter. Tea can't go on for ever. . . . we must make the most of it while it is in a vigorous state and reap the reward." We may leave the Horticulturist out of the question. The gentlemen who grows cabbages and onions generally knows that they will attain maturity in a few months, and he applies fertilisers accordingly: with staple products such as tea and coffee the case is rather different. There are probably few planters now in Ceylon who will not support the statement that the application of artificial manures to coffee was often extravagantly and recklessly carried on. In really scientific cultivation natural conditions must be considered and science and art must work together. "The best returns in the shortest period" is only a paraphrase of the simple expression "over-bearing."

As regards the activity of roots when in search of food, if your correspondent has the courage, let him try this cheap experiment. Take a few bundles of mana or illook grass, or a dozen old gunny bags, and spread them over the ground in tea, coffee or any other product. Then let him after the lapse of three or four weeks, before the grass or bags even reach the stage of decomposition, fork up the soil and see what growth the roots have made in order to get at the new food.—Yours faithfully,

MUSTARD,

MANUFACTURE OF WHITE COCONUT OIL.

Colombo, Nov. 11.

DEAR SIR,—In connection with the discussion now going on in your paper it may interest you to hear that we have been manufacturing white coconut oil regularly for the last ten years.—Yours faithfully,

FREUDENBERG & Co.

[We are interested to learn that this description of oil has been regularly manufactured at the Hultsdorp Mills during the past decade. The question then is,—how does its value compare with "Cochin Oil," and whether it is sold in Europe under a mark which distinguishes it from Ceylon oil generally.—ED. T. A.]

PLANTING NOTES.

SELANGOR PLANTERS' ASSOCIATION.—As will be seen from the summary of a meeting which we publish in another column this Association has had under consideration the question of having a labour-recruiting agent in India, but it has been allowed to lie in abeyance in the meantime. Steps are also being taken for establishing a central coffee-curing store in the State.

TEA PREPARATION BY ELECTRICITY.—The *Indian and Eastern Engineer* returns to this question as follows:—A correspondent of our contemporary, *The Englishman*, under the *nom-de-plume* of "X. Y. Z." writing on the subject of our article on "Tea Manufacture by Electricity," puts on record the fact that Mr. Lloyd originally introduced the *system* on the Darjeeling estate. Mr. Lloyd did originate electrical plant in this garden, but as an amateur in Electricity; and is entitled to great credit for the ideas on the subject which he partially developed. However as stated by us, Mr. Rickie is the first to *successfully* introduce Tea Manufacture by Electricity. *En passant* we hear that Mr. Rickie has been appointed Chief Engineer to Messrs. Finlay, Muir & Co., for all their gardens, and we look for considerable developments of electrical enterprise in connection with their numerous interests.

CACAO IN THE WEST INDIES.—By the last West Indian mail information arrives that cocoa-growers have of late been doing remarkably well. In three months the price had risen by 13s. per cwt. This, after a long depression, has greatly benefited all the colonies not wholly dependent upon sugar. Of late years many have chosen this delightful occupation. The planter's house is in the middle of a grass clearing surrounded by all trees, which in the earlier part of the year are a mass of pink flower. From the house, paths of about half a mile long radiate. Along these avenues on both sides the cacao tree, which is about the size of our own apple tree, is planted at regular intervals, each being allowed a certain number of square feet. Behind these cacao trees are larger trees, required to shelter them. In these leafy avenues the planter has merely to see that his small staff prune judiciously, thin out the immature pods where they are too thick, and keep the trees from parasites. In the best plantations costly machinery for drying and separating the beans has been introduced. Small beans are kept for home consumption, and large beans fetch better prices in Europe than those produced elsewhere, except perhaps Venezuelan.—*Grocers' Journal*, Oct. 23.

FRESH AIR IN BULK: A TRIP TO THE HORTON PLAINS.

To any one who has been long stagnating in an enervating climate such as is found in many of our lower districts, a change of scene even though a short one, with a cooler atmosphere, offers such temptation as hardly requires to be backed by the authority of medical advice. The pity is that we are sometimes not quick enough to grasp the occasion, and by putting off a holiday indefinitely, only prepare the way for a longer holiday, but one in which the only exercise we get is that of patience, while physical exertion is confined to the prescribed exhibition of pills, powders and mixtures. The weather is often made the excuse for delaying a much-needed trip, but without adequate reason: considering how little satisfied each of us usually is with the weather that falls to his lot, it would be only fair to assume that people even a short distance away have some of finer quality.

There are many ways of getting to the Horton Plains, and

THE LEAST TROUBLESOME WAY

is probably by rail to Ambawela or Ohiya station, the distance being short and the road easy; but for a cross-country trip, with plenty of exercise and varied scenery, a walk from Haldummulla *via* Kalupahani may highly be recommended. The elevation of Haldummulla is 3,380 and the Horton Plains some 7,000 feet. But the cart road goes downhill to Kalupahani, and the distance being nearly four miles, there is probably a drop of nearly 800 feet, so that one has a clear ascent of 4,500 feet to make before reaching the pure air on the summit. At the foot of the hills there is a painfully oppressive feeling in the atmosphere and even light clothing seems a burden, but long before the summit is reached a change of flannels becomes necessary.

The town of

HALDUMMULLA

does not strike the casual visitor as a terrestrial paradise. There are two or three native shops well-stocked with tinned provisions, umbrellas, country salt, &c., but a striking scarcity of fruit and vegetables. Not a single lime was to be had for money, the only circulating medium with the Moorish fraternity, and only about a dozen plantains, more withered than ripe, were visible in the whole place. Possibly bolders of plantains were waiting for a rise in the market, but this seems to be their normal condition, and the population are not likely to take an increased interest in fruit before the Last Day, unless a Light Railway drops supplies at their doors. The few small gardens at the roadsides were being weeded and fenced, but

HORTICULTURAL EFFORTS

appeared to be limited to the growing of cabbages and beans. If the School of Agriculture can turn out a few practical gardeners, there is room for one here. The only fruit trees visible about the place, and those very few and for the most part utterly neglected, are mulberries, tree-tomatoes and papaws. Some of the former were carrying a fine crop, but the fruit is generally neglected by the natives, and the bulbuls were enjoying them. In the villagers' gardens at Kalupahani things seemed a little more hopeful: sweet potatoes, cassava, yams and a few chillies being grown. Jak trees and kital palms are fairly numerous but coconuts and arecas are represented by some half-dozen sickly specimens. The villagers seemed to be living largely on hope and short rations until their paddy and chena crops ripen three or four months hence, unripe jak fruits and the succulent stems of certain wild plants being much in demand. Plantain trees, even in the most sheltered situations, are very scarce: the large number of wild pigs and porcupines in the neighbourhood are said to account for the cultivation not being taken up.

CATTLE REARING.

The road, after leaving Kalupahani, is a tavalam road running, or more correctly climbing, up through

some miles of patana, here and there, with a sprinkling of trees, mostly wild figs and 'kahaata,' often mis-called the 'patana oak.' The soil, especially on wind-blown ridges, seems poor and gritty, and the periodical firing of the grass probably makes it annually worse. It seems a pity that the natives should be allowed to devastate such an enormous area as they do 'to improve the pasturage.' If they raised cattle in proportion to the acreage burnt off, we should be able to export frozen meat instead of relying on Australia to supply us. Besides the large area fired each year for the benefit of the owners of cattle, a good deal of promiscuous firing is doubtless done with the object of driving game into convenient places for shooting and trapping.

GREVILLEAS AND PARA RUBBER.

Here and there on the patanas one comes across a paddy-field or a kurakkan chena defended from wild beasts and cattle by walls of loose stone, and cannot help wishing that the cultivation was more extensively carried on so as to remove more stones from the road. In the patana hollows too, below the most westerly of the Kalupahani estates, there are extensive nurseries of tea and grevilleas. About a mile or more from Haldummulla, a small plantation of grevilleas had attracted notice. They had apparently been planted in scrub and patana land and were growing very well with scarcely any vacancies? It seems curious that the Forest Department should, for so many years, have neglected its vast opportunities of redeeming the sterile grass lands of Uva by planting them up with grevilleas and other suitable timber trees, instead of trespassing on the right of private owners by starting extensive plantations of para rubber. Many planters were called upon, some ten years ago, by a circular issued in the Central Province, to give information as to the growth in their districts of some three or four dozen kinds of trees for timber and fuel, including some which were useless for either purpose, but rubber cultivation (with a view to the preliminary expenses being all wiped out by the sale of seed) was not then suggested.

The Government Blue-book for 1892 reported over 825,000 acres of

PASTURE LANDS

available in the colony; since then Mr. Vincent's examination of the country has probably added to this a large area, and the total of course does not include all paddy and dry grain fields, which are available for grazing purposes as soon as the crops are reaped. Even if these figures are above the mark, there is surely ample scope for considerable work in the patana hills of Uva alone. With a Government railway clamouring for fuel, to say nothing of estate requirements, why is this work so long delayed. It may be said in answer that experimental planting some years ago in Dimbula was disappointing; trees grew to a great height and then died out, apparently killed by the same boring beetle which has recently devastated our cacao trees. But is the Forest Department expected to squat, like a sedent Buddha, in contemplation? As regards the boring beetle, it has long been known to attack only trees in an unhealthy condition. Specimens of it were sent, with other insect pests, to the Planters' Association some fifteen years ago. The actual cause of the decay of the gums and grevilleas was most likely the prolonged visitation of cockchafer grubs. A great many of the large brown chafers have been flying about on the patanas in the evening lately, so that there would probably be a large number of grub ready to interfere with any experimental planting. But the aeration of the soil by draining and forking would soon put a check to their ravages, while a careful analysis of the patana soil would show in what chemical constituent, if any, it was deficient.

After leaving the patanas,

THE ROAD IMPROVES

considerably and winds up, at a very steep gradient, through some very fine tea fields and then through jungle till it joins the bridge road leading from Haldummulla to the Plains. Here tree ferns and rhododendron trees begin to get numerous, and in the early part of the year, when the latter are in flower and the varied jungle trees put on their new foliage, the scenery must be enchanting. Many of the wild flowers on either side of the road remind one strongly of those at home. On reaching the Plains, the road becomes easy: a mile and a quarter of comparatively level walking, through the grass land gay with crimson orchids, brings one to the resthouse.

It has been said that the finest scenery in the world is improved by

A GOOD HOTEL

in the foreground, but its attractions are distinctly increased when it is found near the vanishing-point. The garden surrounding the resthouse is bright with flowers, periwinkles, gladioli, cannas and hydrangeas, and the delicious air is filled with the perfume of borders of mignonette, but after a climb of four thousand feet æsthetic aspirations, unless very intense, are apt to be overcome for a time by considerations of the practical measures necessary to restore lost energy. The fresh air of the plains is certainly bracing but one cannot drink in much of it at once, and the suggestion of a draught of the liquid which is popularly supposed to be obtained from fermented grain is irresistible.

But the fine weather may not last all day, and if one of the great attractions of the plains, the view of

THE "WORLD'S END,"

is to be seen, it must be done quickly: a farther walk of two miles. Packets of sandwiches, which at starting seemed more than sufficient, disappear in a galloping consumption: the air makes one feel as hollow as a spectre, but breakfast must be postponed. About a mile from the resthouse, at the side of the road, with the jungle growth carefully cleared on all sides, appears a small log hut. The door has no hinges but is raised some two feet from the ground by a rope tied to a pole fixed horizontally above. The interior is uninviting; the uneven earthen floor is littered with brushwood, and at the farther end a small part of the space is fenced off. The guide explains that it is not a summer-house, but a cheetah trap: no one but a cheetah could feel sure of it. One wonders why no provision has been made for the animal's comfort: there is no dry straw to lie on nor any feeding-trough. There are many break-neck places in Ceylon, but the "World's End" is probably the finest known. Leaving the road at a point where it emerges from the jungle and dips into a saddle, one has only a few feet to step down the grassy slope to obtain a splendid view of the panorama spread out beneath. Cautious movements are necessary: there is no railing to support one and the stunted vegetation growing on the brink would be of little use. With a fresh breeze blowing behind one it is advisable to plant one's feet firmly: the slightest movement to save a blown-away hat might land one fifteen hundred feet in the valley below. The sunlight gradually fades and the air gets colder, and though the thermometer in the resthouse porch marks only 62° the ample fire-place in the dining-room is attractive. After breakfast a tour round the garden was very enjoyable. It is seldom that one finds a garden in which the splendours of Western floriculture are to be seen grafted, as it were, on Oriental luxury, many of the flower-beds are raised on banks of empty beer bottles. The effect is striking and probably also beneficial from a practical point of view: few visitors can conscientiously say farewell to the Horton Plains without making an effort to promote the cultivation of flowers in such an artistic way.

GIPSY JOHN.

COCHIN vs. CEYLON COCONUT OIL.

THE following are the questions embodied in our circular :

1. Have you ever considered the reasons for Cochin Oil selling for 30 to 36 per cent more than Ceylon Coconut Oil ?

2. What is your opinion after having read the article in *Ceylon Observer*, 30th October? (See page 381 of this issue.)

3. Do you think it possible in your District to give the same attention to palms and kernels as is given by the Cochinese according to the description under notice?

4. Any objections or difficulties in your district?

5. In what Districts of Ceylon would you think the best results could be obtained?

6. Would you recommend a Ceylon Superintendent being sent to Cochin to note what is done there from beginning to end; the nature of the soil, cultivation of palm, etc.?

7. Or, would you recommend getting two or three Cochin natives accustomed in copra and oil-making to lead on local plantations?

8. Do you know of any Ceylon estate or district whose copra or oil is always superior to ordinary Ceylon oil, and approximates to Cochin?

9. Any other observations?

The following have been received from well-known planting authorities:—

(Answers.)

No. III.

1. Yes; and if you will look up the *T.A.* for 1895 or 1896 you will find that this question was discussed in the *Observer* and opinions elicited.

2. My opinion is that the great difference is almost, if not entirely, due to the large amount of stearine in the Cochin oil.

3. Quite. Although there is not the same long spell of dry weather; yet copra dried over coconut shell fires can be cured quite as white as sun dried.

4. None except the more frequent rains preventing copra being sun dried.

5. In Jaffna, Kalpenty, Batticaloa, and Chilaw. I am sure that copra quite as fine as any Cochin article can be, and is prepared in these districts.

6. Perhaps it would be advisable. There may be something done there of which we are ignorant, though I doubt it!

7. No; by no means.

8. Answered in No. 5.

9. I am afraid that the difference is due to climate and soil and perhaps, to some extent, to keeping the nuts for so many months before converting them into copra. Is there no reliable person in Cochin from whom information might be got? W. J.

No. IV.

Oct. 5.

1. The difference in price of Cochin and Ceylon coconut oil attracted my attention many years ago. The experts in the trade whom I consulted, referred the difference, partly to Cochin oil being richer in stearine, partly to speculation and combination among owners.

2. My opinion, confirmed by the *Observer* article of 30th October, is that a third explanation is to be found in the fact that most of our copra is smoke dried, much of it positively black, yielding oil which cannot be filtered white.

3. Not the same, perhaps, to kernels, because of the greater humidity of the air and the greater rain fall; but more attention than now. To palms the same attention can be paid as in the most favoured countries.

4. The special difficulty in the way of sun drying in this district is the absence of the sun for a good part of the year. Half the number of days in the year is wet or drizzly, and the sun is often obscured by clouds; but smoke drying is resorted to too readily.

5. In Jaffna, Batticaloa, Manaar, Kalpenty, and Puttalam. If the copra from these districts should sell distinctly better, not only because it is better dried through its long journey but because it is

sun dried, other districts would resort to open air drying whenever possible.

6. It would be an advantage, but it is not absolutely necessary. Cultivation is understood here and is being practised with good results—larger crops and thicker kernels.

7. That, too, may be desirable, but is not essential. Copra drying is a simple process and every one knows that well dried copra is more valuable than damp, and clean is preferred to dirty. There should be an incentive to greater resort to the sun than to fire.

8. The copra of Jaffna, Batticaloa, Puttalam and Kalpenty is generally superior to that of other districts because it is cleaner and better dried, and it fetches better prices, because it contains less moisture. The oil of one district cannot be compared with that of another, as there are no district mills and district oils.

9. For the above reasons I do not agree that it is merely a planters' question. If the mill-owner offers more for sundried copra than for smoke-dried, in order to prepare white oil as a speciality, there will be inducement for planters to avoid smoke or steam drying, except as a last resort. F. B.

No. V.

Nov. 4.

I have not had any practical experience in coconut oil manufacture—so cannot reply to questions 1—7. As regards (8) I can only repeat what I heard from Mr. O'Grady of Karativoe estate, who told me he took home some of his (chekku-mill oil) and submitted it to some large dealers in London, who after examination assured him that it was far superior to ordinary Ceylon oil, and I think he said equal to Cochin; but that to secure a proper price it should come into the London market under some different designation than "Ceylon" oil.

On another occasion I know Mr. O'Grady made some very superior Copra for a local Chetty, who sent it to Calcutta (to be used he said for sweet-meats), but it took a lot of trouble and additional expense and did not pay.

So these facts show it is in the long dry season which prevails on the Eastern side of the that there island could be prepared a superior class of copra and oil.

Mr. O'Grady would give fuller particulars doubtless if asked.

I may also mention that in the Batticaloa estates, the nuts are left (I think for a month) in the (coir) husk before being split—which is done with an axe without removing the husk.

E. ELLIOTT.

No. VI.

1. For the reason that no endeavour is made in Ceylon to export white oil. I saw a sample of white oil in Colombo some time ago, which if exported, should approximate, if not equal, Cochin oil.

2. Except as regards any superiority due to climate conditions, there is no reason why Ceylon oil should not be as good as Cochin.

3. The attention given to palms on my estate is quite equal to that in the description you notice. In the treatment of kernels too, I do not see any difference between our methods and those adopted in Cochin except as regards the use of mats.

4. I believe there is not so much uniform sunshine here as in Cochin, hence we are obliged to have more recourse to fire. In drying by fire there is now no means of excluding the smoke, which accounts for the bad colour. If the smoke could be excluded by the introduction of some kind of Sirocco, I think much of our difficulties may be overcome.

5. Kalpitiya, Puttalam, Rajakadalawa and Chilaw should do well. I believe Jaffna and Batticaloa would also do, although I have no acquaintance with them.

6. & 7. I do not see any necessity of adopting either of the suggestions. Given good weather and good nuts there is no difficulty in making white copra.

8. No.

9. My experience is that nuts of estates on the seaboard make the best copra. I think this superiority is due to the presence of salt in the soil. If some means could be devised for obtaining salt at cheaper rates for manuring purposes and better methods of manuring are adopted, I think our nuts will not be much inferior to those in Cochin, and if some method can be devised of drying copra by means of a uniform heat without smoke, I think we will be able to manufacture a very superior oil in Ceylon. D. J.

We direct attention to two thoroughly practical communications discussing this matter below. One is from the Manager of a large plantation in the Rajakadalawa district beyond Chillaw, which ought to be specially favourable for sun-drying; and the other bears the initials of an old contributor who will be recognised as almost "the Patriarch" among coconut planters, at any rate in the Western Province of Ceylon. The former supplies a great deal of out-of-the-way information as to the careless, if not fraudulent way in which copra is treated by native owners and middlemen before reaching the mills; and both writers seem to make it evident that the Mill Managers are pretty well helpless in reference to reform—since they must take the copra as offered, and it would not be profitable for them to deal separately with small quantities of cleanly superior or sun-dried copra.

But "W.B.L." shows us very plainly how private estate owners in Ceylon, anxious to do as much justice to their nut-kernels as is done in Cochin, can accomplish their purpose. We infer from what he says that a "Sirocco" (or query "Dessiccator")—or even a more primitive contrivance described by our correspondent—would enable copra to be properly dried even in our wetter districts; while in the drier series—which must have as many sunny days as Cochin—the result can be arrived at with a little care more simply and economically. "W.B.L." tells us of a proprietor of 200 acres of coco-palms who regularly prepared his own copra and manufactured superior oil from it on the estate, we suppose at a considerable profit over his neighbours' returns? With this example before them, we do not see why a good many individual planters should not go and do likewise and secure in the London market not £21 to £22 but £29 to £30 for their oil. "W.B.L." says it should pay to erect a Mill (with hydraulic presses) for 50 acres; but to make the venture safer, a Syndicate of proprietors owning not less than 1,000 acres—or why not a Limited Company buying up estates to that extent?—should be tried to establish a Mill to manufacture only superior Ceylon oil. No doubt, a distinctive mark would have to be adopted to secure due attention in the London market. With a margin of from 30 to 36 per cent. to go on, it does not seem to us that encouragement is wanting to deal with an enterprise of this kind.

(No. VII.—Answer to Circular by a
Rajakadalawa Manager.)

I have read the leader in the *Observer* of 30th ultimo with great interest. The superiority of the Cochin coconut oil, as evidenced by the high price it obtains in the London market, is a matter well worthy of our consideration and the remarks made in the leader are quite to the point. The opinions expressed on the subject by the authorities quoted are perfectly correct so that little remains to be added. Considering what

large tracts of land in Ceylon are under coconut cultivation and what vast quantities of copra are prepared, it behoves us to put our best foot forward and see if we cannot successfully compete with our rival, but what is the use of the energy and care of a few when the vast majority of the natives in this island engaged in the coconut industry are notorious for their apathy.

To make good copra, as made in Cochin, three things are of paramount importance:—1st, the choice of nuts; 2nd, mode of manipulation; 3rd, time of drying.

1. With regard to the choice of nuts—these should be thoroughly well matured and dry on the tree before plucking and of a dark-brown colour. Nuts that are so dry that they sever their connection with the parent tree by their own weight and fall of themselves are the best adapted for making copra. The Cochin nuts are so gathered and I suspect this accounts for the larger percentage of stearine in the Cochin oil. By this method two bunches of thoroughly matured nuts may be relied upon from a well-bearing tree and the third or less matured bunch may be left to form the first bunch of the next crop and so on. These nuts should be plucked once in three months instead of two months so as to ensure two perfectly dried bunches. The nuts when plucked should not be left in a heap longer than three weeks or a month by which time the kernel is so far desiccated that it comes away from the shell after a slight exposure to the sun and very often the moment the nut is split. Germinated nuts should be avoided if a first-class copra is to be turned out. The general rule in Ceylon is to pluck once every two months. I think this accounts for the inferiority of our copra, for immature nuts are bound to be mixed with the mature ones even on the best regulated plantations.

2. As regards the manipulation, nuts should be placed in a fierce sun as soon as they are split, care being taken that no sand or earthy matter adheres to the inner surface. Where practicable they should be placed on mats or cadjans till the surface moisture sufficiently evaporates, leaving a dry inner surface to which foreign substances cannot cling. This can be ascertained by passing one's fingers over the inner surface a few hours after the nuts are exposed. When this amount of dryage is ascertained and the kernels are detached from the shells, mats and cadjans are no longer needed, as the kernels may then be placed on the bare sand (the looser and whiter the sand the better) till thoroughly dried, without any fear of taint. Where large quantities of copra are prepared at a time it is not always feasible to effect the preliminary drying on mats and cadjans, but it is trouble well laid out when the ulterior benefit is taken into account.

In Ceylon the natives are very careless as to what becomes of the nuts in the splitting. They are split and chucked about anyhow, rolling over muddy ground or dirty sandy soil clogged and damp with coconut water or over patches of cattle dung or any dirt that is lying unswept. The nuts are then spread out to dry with a large percentage of earth sticking to them thus rudely spoiling their snow white appearance. The earthy matter leaves its stain and quantities of sand are embedded in the body of the kernel. This is regarded by the natives as the proper thing to happen as it increases the weight of the copra. I have seen sand actually thrown on the newly split nuts for this very purpose. How is it possible to obtain a good merchantable copra when men are capable of such nefarious practices? In some instances the coconut water is not all out of the split kernels when exposed to the sun, a small portion at the bottom is allowed to remain and evaporate slowly (as it is too much trouble to throw it out) and in this slow process of evaporation a sticky gummy substance is formed which clings to the bottom of the kernel and readily holds any rubbish that may eventually come into contact with it.

The kernels should be placed closely side by side to dry, but no nuts should be split after 11 a. m. as those split in the morning get the benefit of a full day's sun, whereas those split in the afternoon may, or may not, get a dry inner surface by the evening. This is an important factor in the drying process, for damp on the inner surface all night long is

apt to engender a sticky substance which may induce mildew before the sun rises next day and present a sorry appearance in juxtaposition with the better dried kernels.

The kernels should be placed in long narrow heaps about 8 inches deep and covered with cadjans before nightfall so as to prevent the dew getting on them, as any watery interference with the oleaginous surface is most detrimental to the unique colour of the copra. These heaps should next day be spread out again in the sun, as at first, and so on till perfectly dry.

Kernels dried on sandy soil dry quicker than those on ordinary hard ground, as the heat of the sand at the bottom is intenser than that of common earth, and helps to dry the kernel faster. A white colour is produced by hard bleaching.

When the kernels are well dried (which can be ascertained by a sharp snapping sound they make when doubled and pressed in the fist and by an even leaden line perceptible in the broken portion where the escaping oil stains the outer surface) they should not be allowed to sweat too long in heaps. The sooner they are despatched to the mill the better for the oil they are expected to yield. Mildew forms thickly and rapidly and is most prejudicial to the making of a colourless oil; but with a nice, even, snow-white inner surface and a thoroughly sundried kernel, I don't see why good colourless oil should not be made in Ceylon equal to that of Cochin, provided no other copra of inferior quality is mixed with the good lot crushed. The heterogeneous mixing of all kinds of copra in the mills is a great evil. If good, bad and indifferent are all crushed together it is impossible to get any other than the amber coloured oil now in vogue, which, when congealed, gives a palish yellow hue instead of alabaster white. The excess of stearine in Cochin oil, which makes it preferable for candle-making purposes, is, I suspect, due to the excellence of the nut and not to the superiority of the soil—an excellence attained by full maturity and a regular system of manuring the trees—for the soil of the west and north-west coast of Ceylon compares favourably with any soil in the world as a feeding ground for the coconut palm.

3. As regards the time when copra should be made I am convinced that the hottest and driest season of the year before the advent of the south-west monsoon (*i.e.*, between January and June) is the best, because it is the most reliable for heat and rainless days. Copra, to be white, should have no interruption in the process of dryage, save that of the night. It should run no risk—no heat but sun-heat being used. If it has to be transferred from the drying-ground to be finished off over the "Attoowa" fire in the event of clouds or rain intervening, then good-bye to the hope of making a pure white copra. The smoke of the coconut shell-fire soon leaves its tell-tale mark on the inner surface and a browned, if not partially blackened, copra is the result. If the heat brought to bear on the kernels is not unique and continuous, a brownish tint is observable on the borders and this tint is bound to tarnish the oil expressed therefrom. Should rain-drops find their way to the copra whilst drying a spotted and motley appearance ensues and these spots of many colours, in the development of mildew, can never be removed, no matter how severely they may be subsequently dried. Undoubtedly the colour of the oil is affected by these accidents. Rain and dew are the enemies of copra and should be carefully guarded against.

In Ceylon copra is made all the year round and plays at hide and seek with all weathers and consequently much damage accrues; but given a good season of the year, a well matured nut, thorough cleanliness of manipulation in a powerful sun and careful handling in the mill, and it would be hard lines indeed if we could not compete with Cochin. Good white copra has been turned out from heating rooms, so well constructed as to be impervious to smoke and maintaining an equable temperature regulated by a thermometer. The heating room, if in good order, makes one independent of the weather, and if it involve no risk, should be resorted to by all proprietors of estates who turn their nuts into copra.

Nov. 6.

(Answer by an Old Coconut Planter No. VIII.)

Nov. 8, 1897.

Few parts, of the coconut districts of Ceylon, enjoy sufficient sunshine at all seasons, to dry copra without more or less damage. These unfavourable climatic conditions, are not the only causes of injury to this product, as it is usual to sell the nuts on the spot, to middlemen, who make a trade of it, and probably, three fourths of the crops of the Island, pass through their hands. It is of course their business to make as much profit as possible on their transactions, and as a large proportion of the original weight is moisture, it is an object to get it to market, with the greater part of the moisture retained. It is therefore put into a rude kiln after a few hours in the sun, not to dry, but to be smoked which prevents mould and rot from setting in at once. Thus most of the copra brought to market, is discoloured with smoke, and contains at least 50 per cent of its original moisture. The large buyers, therefore regulate the price according to the average quality, the only distinction being boat and cart copra. This seems rather a curious method of arranging prices, but there is some reason in it; boat copra comes chiefly from the dry climate, to the north of the Mahaoya, where the drying process is less liable to be interrupted by rain, and if only half dry, when put into the boat, the drying goes on during the voyage of ten days or a fortnight, and, it is perfectly dry when it arrives in Colonibo. On the other hand, the cart copra is collected from the country round Colombo, within a distance of say thirty miles, and consists of the smoked article of the traders, and the still more carelessly prepared produce of the villagers. I do not know whether any change has taken place, since I was familiar with the working of the oil mills, but then all copra that came in, was thrown in one heap, and taken to the stores as it came to hand. This produced a dark-coloured article which is still—I believe—the character of all Ceylon oil, and so it must continue, so long as the bulk of the copra comes through the trader and the villager.

Perfectly ripe nuts, cleanly and thoroughly dried, consists of 66 per cent oil, and of ponce 34 per cent. The chechu cannot extract more than 60 to 63 per cent of oil, but the grinding stones and hydraulic press can do more with the same material; but with the common quality of the copra delivered at the mills the yield must be much less. Perfectly clean and dry copra yields an oil, that in a glass, beside another of spring water, the eye cannot distinguish a difference. Whether Cochin oil is intrinsically superior to the produce of Ceylon, is a question for the chemist to decide; but there can be no doubt that clean colourless oil, would command a higher price in the markets of Europe and America, than the smoke-stained article now supplied. There is not however the least hope, that the trader and the villager, will spontaneously improve their methods, and the mill owners probably make more profit on the existing system than they would do by a superior article.

The only hope of raising the quality of Ceylon oil, lies with the Europeans who are going in for coconut cultivation, which they may do, by rendering themselves independent of the nut dealer, and the mill owner. It has been done before, and can be done again on the same or improved lines. A coconut estate planted in 1840 about 200 acres, owned by a non-resident European, manufactured all its copra on the spot, for over twenty years, with very satisfactory results. This was done by chechus; but a property of 500 acres, could afford to have its own mill, or several neighbouring properties might join in it convenient; at all events in a coconut district, nuts to keep the mill going could always be purchased, at current rates. Every coconut estate should have an apparatus, for artificial drying. Without that, no one can prevent copra all the year round, from getting mouldy and spotted. A sirocco would do first-rate; but there are cheaper means of attaining the end in view; anything will do that carries the heat without the smoke, say a sheet iron platform, with a fire of dry coconut husk, five feet lower giving out heat without flame, and raising the temperature of the chamber

above to 150 deg., which if kept up for 48 hours, will thoroughly dry the copra, and so clean and bright, that the oil made from it will be perfectly colourless.

Once on a time, the Engineer of one of the Colombo oil mills, showed me a phial of clean bright oil, which I duly admired, and asked by what process he had got it. He replied, that was his secret. Do you propose to take out a patent? I'll consider of it, he said. Well I think you had best not go to that expense, for I could show you tons, as pure as that, and any one is free to inspect the process; it merely amounts to this:—'clean copra makes clean oil.'

Ceylon may not be able to compete with Cochin in quality; but it is in her power, to make the best of the material she has to deal with, and thereby gain both credit and profit. W.B.L.

We append some half-a-dozen additional answers to our circular-questions on this subject, so closing the discussion for the present. We trust, some practical good will come out of it. We may say that the whole of the correspondence and remarks will be embodied in our forthcoming Coconut Planter's Manual. There can be little doubt, we think, that as regards both copra and oil from our dryer districts—Jaffna, Batticaloa, Kalpitiya and Chilaw—only, as Mr. S. C. Munro hints, "a bad name"—a confounding of the superior with the general character of "Ceylon" copra and oil—can account for the value being placed lower than for Cochin. If that be the case, it rests with proprietors themselves we think to get matters put on a proper footing. Let them obtain standard samples of Cochin oil and copra from their Agents, and then challenge comparison when they feel, in the dryer districts especially, that they have attained to the same standard. At the same time, experiments in the directions pointed out by "J.D.V." and other correspondents could not fail to yield interesting and perhaps, profitable, results. "W's" idea of using a "Clerihew" for drying copra in the wet season is a very good one, and we hope to hear of success.

Answers to Circular: No. IX.

AN OFFER OF WHITE COPRA TO COLOMBO,

Nov. 7.

1. Yes. The reasons given in your issue of the 30th ultimo, are to the point. We of Pallai turn out much better copra than estates in the South, but nearly all our copra used to be shipped to Cochin! At present there are no purchasers here for the Indian market. In consequence price of copra has fallen, and we have to sell to the oilmongers.

2. I think it quite possible to make good clean copra rivalling that of Cochin, and indeed our copra is perfectly clean and white. I don't think there is much room for improvement over the Cochin treatment either of soil or kernel, though we don't use mats on which to spread the copra.

3. Matting would be excellent, but expensive. We heap the copra on the approach of rain and cover with *kudals* made of palmyrah olas and jungle sticks.

4. The only disadvantage is, this copra, if not sufficiently dry, is apt to get soiled and discoloured by heaping. Perhaps tarpaulin would be better to cover with, *without* heaping the copra.

5. Best results can only be obtained in the districts where the rainfall is lowest like Pallai: 40 in. average per annum. In the South when the copra is fired, it is sure to be discoloured, and the oil expressed from it to be anything but limpid.

6. I am not quite sure if a Ceylon man could profit much by going to Cochin? I think it had better be left to individual effort.

7. However I won't speak dogmatically on the subject. But I certainly should prefer the course suggested in (6) rather than get Cochin run over.

8. I think it is quite clear from what I have already stated that Pallai copra is just as good as the Cochin copra. The oil here is perfectly clear.

9. I was about to write to you when this paper came to hand, *in re* the quality of the nuts.

There cannot be any material difference between these and the nuts of the Western or Southern Provinces, or even those of the Cochin Coast—at least so far as they contribute towards the clearness of the oil. The so-called "superiority" of the copra is simply the *whiteness* of the copra which is entirely due to careful preparation, and fine weather. We have from 8 to 10 months of dry weather, which people in the South don't have. Hence our copra is whiter and better in every respect. We spread out the nuts when split open on fine white hot sand, and the copra is thereby subjected to heat both on *top* and *underneath*. Thus the kernel comes out quite crisp and dry and perfectly white from the shell. It is only when we are disturbed by rain unexpectedly that the copra suffers and is apt to get discoloured and mouldy. It also gets soiled by being thrown about during heaping and then spreading out when the sun shines. The one problem that has been simmering in my head for the last 11 years since I settled here, is, how best to cover the copra *without* heaping it on the approach of rain. Tarpaulin might answer, but I have never tried it: and I am not sure if it is without disadvantages. My second question is what do we gain here in the North by our copra being whiter, seeing that we do not get a higher price for it than people in the South. Supposing we take more than ordinary care with our copra and make it extra white and clean, what are the chances of getting higher prices, and what should be done to secure that end? There being no demand for copra in Cochin, local merchants do not buy copra now. Our price is regulated entirely by the prices ruling in the Colombo market! It is as a rule 4 less per candy at Jaffna than the Colombo price, with its inferior copra. If, indeed, the Colombo Oil Manufacturers offer us sufficient inducement, I, for my part, can guarantee to supply good, clean, white copra, quite equal to the Cochin copra in all respects.

One disadvantage of spreading out the broken nuts on mats instead of on hot sand is that it does not get the benefit of the hot sand, and I venture to think that spreading on mats is not a very great advantage any way. I don't think the copra would be any cleaner by the precaution.

I dare say that in Kalpitiya and Pattalam they should be able to turn out just as good copra as here. Good well-matured nuts, (especially dropped nuts) *sun-dried*, without being exposed to rain, will make excellent copra. I don't think you have the climatic conditions necessary for the preparation of copra of superior quality, either in the Western or in the Southern Province.

JOHN F. PHILLIPS.

No. X.

In answer to your circular on the above subject, the disparity between the prices for Ceylon and Cochin oil attracted my attention long ago, and I discussed the subject in the pages of a contemporary about a dozen years ago. It was then said that the reason was in the Cochin oil being richer in stearine than Ceylon oil. Coconuts in Cochin were said to be stored on covered *messas* or platforms, under which small fires were lighted, till the nuts were quite dry and had absorbed all the water or milk in them. They were then converted into copra. Of course this method of dealing with coconuts can be practised only by small peasant proprietors and is not possible on large estates which have to deal with hundreds of thousands of nuts at each picking, and when two crops are on the ground at the same time.

I think the proprietors of the large oil mills in Colombo will be able to inform you whether Cochin oil is richer in stearine than Ceylon, and how the white oil they turn out compares with Cochin as regards prices.

The communication of the retired Colombo merchant is very interesting and instructive. What he says about the application of ashes to the coconut tree only supports Mr. Cochran's recent analysis, that Potash is the leading mineral constituent of the coconut palm. Potash manures ought to be the principal manure for coconut trees, especially in sandy soils which are poor in potash, but not I think the only manure. It is gratifying to know that I am practising the style of cultivation which he says is practised successfully in Cochin, *i.e.*, turning up the soil round the trees and leaving it in little clods. The advantages of thus aerating the soil are too apparent to need explanation. I always dig in manure round the trees, and do not apply it in circular trenches, and I leave the clods of earth as they are. Further, to prevent them from being battered down by the rain and caked by the sun, I use a mulch of coconut leaves and weeds. The loosened soil is then kept free and open for a considerable period. This is especially important in heavy soils which cake as hard as cement in dry weather. A friend, who followed my advice on a heavy soil, was full of the increased freeness and porosity of the soil which resulted from this treatment.

What your merchant friend says of the color of copra from germinated nuts is true. Desiccating mills will not use these as the stuff turned out is quite yellow. Copra likewise from these is quite discolored and if dried over fires turns out black. Of course it is not possible for large estates to dry nuts on mats, but b'rbacues are possible and should, I think, be made on every estate making copra. The disadvantages of keeping nuts to be cured till dry weather sets in, are that left out as they of necessity are in the open, the bottom layer of nuts go bad or germinate even when the nuts are well spread out.

2. There is the delay in realizing their value. I think that with a little attention means could be devised to dry coconuts white over fires. That this has not been done yet is, I think, a reproach to all coconut planters. I know of experiments that have been made but have been unsuccessful owing to sufficient thought not having been bestowed on them. Fire or smoke should not be allowed to come into contact with the nuts, especially in the earlier stages when they are not quite dry as they then get readily discolored. I think a simple plan would be to have sheet iron immediately under the platform of "waratchies" on which the nuts are placed.

Unfortunately everything on a coconut estate is done on the "cheap Jack" system. On coffee and tea estates expensive stores were and are built, and much money spent on up-to-date machinery. Not so on coconut estates. Everything is of the most primitive kind, and "cheap and nasty" is the rule.

3 and 4. Quite possible to give the same attention in this district and elsewhere to copra curing and cultivation as in Cochin, but since I came here we have had very little continuously dry weather. If after coconuts are split they have not two days at least of fine dry weather the copra gets mildewed. But after this, fire drying does not discolor the stuff.

5. Puttalam, Calpentyn, Jaffna, Batticaloa and last Chilaw.

6 and 7. Hardly necessary. Copra curing is well-known here and we can dry white given the weather and failing that proper appliances, *i.e.*, a well-fitted hot room.

8. Calpentyn copra always ranks first in the Colombo market and Marawilla second. I do not know whether Jaffna and Batticaloa copra fills a large place in the Colombo market, but if it does there is no reason why it should not be classed with Calpentyn.

9. Answered fully in the beginning of this paper.

I do not think it advisable for the copra to be in direct contact with the fire-heated iron sheets. If a "messa" of "waratchies" will not live over the heated iron, wont perforated iron do?

B.

No. XI.

1. Yes, but could not fathom it, as some years ago, and (I believe even now), all copra from Jaffna was shipped to Cochin and the oil extracted there.

2. My opinion is, that it is not so much the copra that is to blame, but the mode of extracting the oil.

3. Yes.

4. No. Considering it to be the driest district in the island more or less.

5. Jaffna and Batticaloa.

6. Certainly. A good idea.

7. Certainly I should also recommend getting some Cochin natives.

8. No.

9. I do not think the tint observed in the oil has anything to do with delay in collecting and making into copra, and nuts should always be allowed to lie in husks for at least a fortnight or three weeks.

T.

No. XII.

November 11th. 1897.

1. Yes, and in my opinion

2. The vast difference between the price of Cochin oil and Ceylon is due principally to the better quality of copra the Cochin country is turning out.

3. I do not see why in dry districts the palm should not enjoy the same attention as it does in Cochin, and so with the kernels, if not all the year through at least most part of it.

4. My district is one of the wettest and in such localities unless expensive factories are provided, with rooms heated by steam and free of smoke, the quality of the copra must be inferior to that of the dry district. It is unquestionable, though, that with care and cleanliness our present means should be sufficient to secure a quality of copra nearly as good as that now produced by our dry districts, and these in their turn go much nearer to Cochin. The colour of copra does not depend solely on the means of heat (sun or fire), but a great deal on the handling while curing. In wet districts it is in fact a matter of repeated handling and shifting from the drying ground to the drying tray, layer upon layer, and from this again to the ground. It is during this handling that the fibre dust of the shells, and other dirt sticking to the gummy kernel spoil the appearance of the copra. This could only be avoided by having commodious hot rooms with plenty of trays where on only one layer of kernels should be spread, but as long as our copra must be heaped up on a single drying tray eight to ten layers, one over the other it will never turn out clean.

5. This is not the case in dry districts, where the split nuts once spread out on a mat to dry, and simply covered at nights, can be left there until ready. Those districts certainly should be able to give better copra than what they give at present.

6 and 7. Systematical, clean sun drying, or improved accommodation for artificial drying, and well matured nuts are, in my opinion, all that is wanted; hence not much to learn in Cochin, by a superintendent from Ceylon nor from a Cochin man here.

8. No, but I know of one estate in a wet district (with 128 inches up to 31st October) obtaining for its copra as good a price as Maravilla.

A NEW HAND.

No. XIII.

1. I have.

2. The principal cause is a bad name as regards the oil of this district, Batticaloa.

3. It is always done.

4. None.

Batticaloa, Jaffna and Kalpitiya

6. I would not.
7. No.
8. Batticaloa, Jaffna.
9. In Buenos Ayres foreign wool growers can never obtain Australian prices from the bad name due only to the filthy condition of native wool.

S. C. MUNRO.

— — —
No. XIV.

1 and 2. Dr. Watt in his Dictionary of the Economic Products of India, says that to produce fibre of the purest hue the green or unripe coconuts, *i.e.*, about ten months old, are used in South India,* and it may be that in this fact we have the explanation of the superiority of so-called "Cochin oil," with reference to which, too, Dr. Watt says that "he is almost forced to the opinion that by 'Cochin oil, as with 'Cochin coir,' may be meant the superior qualities of the oil derived from the Madras Presidency." Several gentlemen connected with the coconut industry of South India have told me that nuts are not allowed there to thoroughly mature before they are plucked, as the fibre of the immature nut is so much superior to that of the mature, and the oil, though less in quantity, is superior in quality. Another difference from Ceylon practice pointed out to me was that the nuts are not allowed to wither as with us for two to four weeks (and sometimes even as many months waiting for better markets) before they are husked, but are husked within a day or two of their being plucked for the sake of the fibre from the green husk and presumably the kernels are dried at the same time as well. Ceylon experience in the preparation of cooking oil and hair oil also shows that a superior white oil is obtained from the immature or rather partly mature nut. Our cooks, too, prefer such nuts in the preparation of curries. A careful series of analyses of samples of best and monsoon Cochin and of Ceylon oils extracted from nuts at various degrees of maturity and withering is very desirable.

3 and 4. The Ceylon growers and dealers would be only too glad to pluck their nuts earlier and dry them sooner, if it be the fact that less maturing on the trees and withering in the heap, would pay them better. But as for more careful preparation of copra than is the practice now, I do not think that is likely.

5. In the drier districts, that is where the air is least humid, Jaffna, Kalpiya, Puttalam, portions of the Kurunegala district and Batticaloa.

6. Yes. Will W. J. oblige? His long experience, open mind and clear judgment would be invaluable in such an investigation.

7. We have a large number of Cochine working our chekkus and at our oil mills, and I suppose they are also to be found in our larger gardens.

8. Answered in 5.

9. I shall test on a few acres the value of "pruning" off the stalks that have borne fruit. Does the sap continue to nourish these stalks? If so, the advice to prune, seems sound; but would the bleeding of the sap not attract the red beetle?

J. D. V.-d-S.

— — —
No. XV.

1. Ceylon can produce as good oil as Cochin. The fault is that the men do not pick the nuts when mature. Natives as a rule send small quantities to the market, and the market people make copra from all sorts of nuts which are discoloured by their method of drying and smoking them. I am of opinion that we should dry our copra in a Clerihew's patent, similar to that used for coffee and the husk and shell could be used as fuel. Mr. Levy of Levy Bros. & Co. told me that they kept the coconuts on a shelf above a fire-place for two months and this caused the oil to be clear and good. I have seen some oil extracted from desiccated coconuts which was as clear as water. I mean by and by to have a Clerihew's patent and to dry my copra by hot air.

2. We must dry our coconuts in the sun or by steam.

3. Certainly. I for one will do it.

4. No. Where there is a will there is a way.

5. If we dry our coconuts by hot air and carefully pluck, I believe all the districts in the island will produce good results. In Jaffna, Batticaloa, and these places the copra is better simply because it receives more attention than in the other places.

6. I do not believe there is anything to be learned.

7. No.

8. No.

9. I am fully convinced that if our coconuts are dried by sun the oil will be every bit as good as that of Cochin.

W.

— — —
SOME TEA FACTORY DEVELOPMENTS
IN CEYLON.

Much has been recently written about the over-production of tea in Ceylon by the opening up of new land, and the fear of a lowering of prices by the increased output. While the discussion has not particularly affected (if at all) the arrangements to open up more land for tea, it has neither prevented an extensive additional expenditure of money in connection with further accommodation and improvements for an increased output of tea in the principal tea districts of Ceylon. This does not apparently indicate that there is much deep conviction that tea production is being overdone, and that the industry has come to a precarious position in view of increased output, low prices, and high exchange. It rather indicates a commendable determination on the part of many proprietors of estate property that not only shall their properties be maintained at the highest attainable productiveness, but also that the cry of deterioration in the manufacture of the tea shall cease to be true, if at all true, in the case of their estates. It is an undoubted fact that want of proper factory accommodation for tea manufacture is not only (to use an Irishism) an expensive economy in regard to output, but that this want of accommodation results in the production of an inferior quality of tea. This has been proved over and over again. We are glad to see these and other indications of wideawakeness in consolidating the industry, and hope the efforts to maintain and improve estate factories as indicated below, will prove, not only commercial successes to the engineering firm concerned—an important local industry in itself—but will stimulate other tea proprietors to similar efforts for the general improvement of the quality of our staple industry. It was with these reflections that the activity in regard to Factory accommodation was brought to our notice recently, and now we are pleased to give some particulars as follows:—

Among the engineering firms of Ceylon, Messrs. Brown & Co. of Colombo, Hatton, Norwood, Maskeliya and Nawalapitiya have recently shown great energy and push in regard to business extension. While the Hatton branch is generally full up with heavy work, the branches at Norwood, Maskeliya and Nawalapitiya are also busily pushing on with the lighter, though not less important operations, incidental to factory additions and buildings in extensive and important planting districts. Their principal branch at Hatton is under the efficient management of Mr. J. Grieve, who has also a general control over the branches; Mr. R. B. Stewart is engineer in charge at Norwood, Mr. Geo. Brown is engineer in charge at Nawalapitiya. The Hatton branch (in the charge of Mr. Grieve) of Messrs. Brown & Co.'s engineering business is the largest. They have over one hundred and fifty hands constantly at work there. In spite of ex-

* Nuts mature with us when about 12 months old.

tension to Norwood and Nawalapitiya, there is little decrease in the work turned out. Here all the heavy iron castings are done, besides other heavy iron work, and it forms an important centre from which the other branches can be worked.

Among the engineering work at present in hand is a complete factory for the estate of Ferham in the Dimbula district. The factory will have an output capacity of 150,000 lb. made tea. It is to be 40 feet by 84 feet in size. The motive power is to be a 14 horse-power oil engine, and a full complement of tea machinery is to be erected.

Wanarajah factory is having an extension of 60 feet by 40 feet made to the main wing.

An entire remodelling of Tunisgalla factory. Rangalla, is in hand, with an addition of 100 feet by 40 feet. There is to be laid down for this factory a 20 horse-power Pelton wheel.

At present the Norwood branch is exceptionally busy with a large number of orders from estates in the surrounding districts, and Mr. Stewart has his hands full for some time to come. Among the orders in hand are the following:—

A new factory for Gangawatte estate, in Maskeliya. The factory is to be 87 ft. by 40 ft., and like almost all new factories is to be built principally of iron with the roof the full 40 feet span. The motive power is to be a Pelton wheel of 20 horse-power, working under a 240 feet fall. There will be two rollers, one a 32-inch "Rapid" and the other perhaps a smaller one, two driers, one a down-draft No. 3 desiccator, Brown & Co.'s sifter and roll breaker (invented sometime ago by Mr. Stewart himself). It is expected that the capability of this factory will be a 200,000 lb. output.

Another order in hand is for Forbes estate in the same district where they are partly converting an old coffee store into an extension of the tea factory. Additional motive power is also to be introduced in a 15 horse-power Pelton, driven under a 630 feet fall. This is supplementary to a 10 nominal horse-power steam engine, put in some time ago. Last year a full complement of machinery was put into this factory which included, two 32-inch "Rapid" rollers, two No. 3 desiccators, sifter and roll breakers. In connection with the introduction of the water power, 1,900 feet of 5-inch diameter top-welded steel piping will be used, besides 500 feet open spouting to bring the water along the edge of a precipice to the piping.

In the Agras, Iona estate is having erected a very big factory 60 feet by 30 feet for which Norwood branch has secured the iron work contract. The girders are to be carried across the whole building without support in the centre. There is to be installed an 18 horse-power turbine and other machinery to turn out a total of 170,000 lb. of tea.

Another factory in the Agras for "Caledonia" estate has just been finished. It is almost similar to the Gangawatte estate factory already referred to, and has a 20 horse-power turbine, with a 16.3 feet head of water.

A 20 horse-power turbine is being laid down for Kotagalla estate, Bogawantalawa. At present this factory has a 30 feet water wheel and this turbine is therefore supplementary.

The iron work of a factory extension of 60 feet by 48 feet on Bogawana estate, Bogawantalawa, is another order in hand. There is also to be a 25 horse-power turbine and some new machinery laid down, which will entail an entire rearrangement of the present factory machinery.

An extension to the factory of St. John Del Rey estate, all iron, and 40 feet by 40 feet, has just been finished.

It is only ten months since Messrs. Brown & Co. extended their business: since then Nawalapitiya has become quite an engineering centre under the able management of Mr. G. L. Brown. An extensive workshop with engineering plant has been erected, and a pile of work is being turned out there. Since Mr. Brown went to Nawalapitiya, Little Valley and Ardross have been supplied with Pelton wheels.

A complete factory with a steam engine and 24 horse-power boiler is being completed on Rattewatte estate.

Donside, Gampola, is having a new factory built, for which Messrs. Brown & Co are preparing the ironwork.

A new and extensive withering-house is being built on Sanquhar estate, Gampola. The size will be 76 feet by 35 feet.

Mount Temple estate, Gampola, is having an important addition to its machinery.

A Pelton wheel of 15 horse-power, under a 490 feet fall, with its connecting water course and piping is to be laid down on Raxawa estate.

Tellisgalla estate factory, Kotmalie, is to have an extension of some dimensions.

A Pelton wheel is to be installed at the factory of Dangkaunde, Rangalla.

The erection of new machinery cannot go on for ever; Messrs. Brown & Co. by having machinery at every branch have laid the plant down, so that they are able to cope with machinery repairs of any description on the shortest notice. One of our representatives was shown round the Hatton and Norwood establishments the other day, and was surprised at the various and large quantities of stores kept in stock. Mr. Grieve informed our representative that they had been slightly inconvenienced in the engineering department by the slip, but that, owing to their large stocks and the goodness of the Railway Company, they had not suffered much inconvenience in the store department.

In connection with their large store at Hatton, the firm has a most efficient aerated water manufactory, fitted up with some of the latest appliances for rapid work. Owing to the slip they have recently been working at high pressure to keep up with the demand for their aerated waters.

The Colombo headquarters are mostly used for forwarding and commercial purposes. The other places have not only engineering works, but the firm have attached to each a general store of large dimensions from which they do a large and increasing business. Mr. Pearson stationed in Colombo, controls the store business and acts in the capacity of Commercial Manager.

PLANTING NOTES.

CHOLERA AND PLANTERS.—The Indian Tea Association has, we understand, recently engaged the services of a Dr. Mulheim in introducing his cholera specific in the coolie depôts. The Doctor has accepted the moderate remuneration offered him *i.e.*, Rs150 a month and all his travelling expenses for three months, and proceeds to Gauhati.—*Planting Opinion.*

SALE OF A COCONUT ESTATE.—Mr. Bastian Fernando, plumbago merchant of Kollupitiya, has completed the purchase of a coconut estate about 300 acres in extent at Haldanduwana, in the Chilaw district, from certain villagers, about 30 in number, who held the land in common. The estate is fully planted, part of it being in bearing, and is situated opposite to the Ceylon Tea Plantations Company's property in the same district. The price paid was Rs60,000, and the negotiations were carried to a successful termination by Mr. Ekanayake Mudaliyar, the well-known broker and commission agent.

COFFEE: MARAGOGIPE HYBRIDS.—A Nilgiri planter draws attention to the good effects of hybridisation. He writes: "I was much struck with the good return of last season's coffee from one of my places, and pleased with the large proportion of A. A. size. I attribute it to my having some years ago filled up the vacancies with Hybrid Maragogipe plants. The neighbouring plants seem to have been 'inoculated,' so to speak. I have a field of 5 acres of them just coming on. They are remarkably healthy and free from disease. There is no doubt about it; we have gone on too long planting Arabica, and the introduction of a fresh strain is desirable."—*Planting Opinion.*

TROPICAL PRODUCTS.

Mr. Raoul, chemist, who had been commissioned by the French Government to go to the Malay States in order to discover the plants which might be of utility for supplying raw materials to industry and commerce, has just returned. The mission of which he was the head was able to penetrate into unexplored forests, and to bring back some valuable plants destined for cultivation in French possessions. These consist of new textiles, india-rubber, some species of gutta-percha, some of the latter quite unknown as yet, some trees producing vegetable butters and greases, oils, resins, varnishes, and tannins. The immense island of Sumatra, which was visited, is almost unknown in the interior. There the mission found veritable riches, amongst which gold, which they were not seeking, and have located the presence of petroleum and discovered immense forests of trees, producing resin, india-rubber, and gutta-percha. All that wealth remains unutilised for want of workers, because the natives are apathetic, ignorant, and cannot be employed as labourers.—*London & China Express*.

PRODUCE AND PLANTING.

RUSSIAN CENTRAL ASIA AND ITS TEA TRADE.—In the last report from the British Consulate-General at Meshed some space is devoted to the tea trade of Russian Central Asia. Tea and indigo are the two main exports to these regions from India. Russia has now begun to cultivate tea in the Batum district with some success, but, although it is said that tea enough to satisfy the requirements of the Central Asian market will be produced here in time, it is evident that the Russian planter will not be able to compete with the Anglo-Indian for a long time to come. The bulk of the tea from India and China into Central Asia now goes by the Batum route in place of by Bandar Abbas and across Persia. At the end of last year it was stated in Bokhara that the Russians were trying to deprive Bombay of the trade in Chinese green tea by creating a direct demand between the Bokharan dealers and Russian agents in China, and also by inducing the Peshawar merchants trading in Bokhara to purchase in China and import by Batum. As the latter were representatives of Indian firms, they did not alter their commercial routine; but it seems clear that there is now direct communication between Russian houses in Bokhara and in China and direct purchases and sales between them, mainly of green tea, consignments being shipped direct to Batum. This involves loss to India, where great profit was made by importing green tea from China and then exporting it to Central Asia. But India has not lost the trade yet by any means. Indian traders in Bokhara continue to make their purchases in Bombay, and have them sent by Batum in place of Bandar Abbas. Thirty-six to fifty days is the time taken from Bombay to Bokhara by Batum. This is much shorter than the Persian route and the cost of carriage cheaper; but the Batum route is said to be unpopular with the Indian trader, for he has to pay the customs duty in cash at Askabad or Bokhara immediately on the arrival of the goods there, whereas by the Persian route the Persian forwarding agents paid all dues and charges and recovered them afterwards from the consignees without requiring any advances. Hence Indian traders are making inquiries about the new route from Quetta through Seistan into Khorasan, as they think it might suit them better than the Batum route. The Indian traders residing in Bokhara are natives of Peshawar, Rawal Pindi, and other Punjab districts, and prefer buying near their homes in India. Hence it is suggested that the tea planters in Kangra, Dehra, and other places

in India should endeavour to recover a trade which was wholly in their hands twenty years ago. They can beat the Chinese green tea imported by Russian traders, for their tea is of better flavour and cheaper, especially now that the Indian tea will have no heavy Afghan duties to pay by the new Seistan route. But it will not do to wait for the traders to come to the Indian gardens as they used to do; the purchasers must be sought out in Quetta, Karachi and other places in Upper India. In this way the Indian planter might be able not only to secure the green tea trade of Central Asia, but also a trade in black tea in the Seistan and Khorasan markets, and perhaps elsewhere in Persia. "Were a European Persian-speaking commercial agent deputed by the Indian tea companies collectively to travel in the country to study Persian tastes and ascertain the quality of the tea that may be in demand, and then to advise them to produce suitable tea especially for the Persian market, and make arrangements for its direct export and sale through a central depot in charge of a European or trustworthy Indian agent, the Indian tea trade with Khorasan might be expanded to a large extent even now."

A TRAVELLER'S TALE.—The opponents of tea drinking, who are always on the look-out for an objection wherewith to point a moral, can find one if they turn to the columns of the *Boston Traveller*. As that journal may not come within their range of vision, we supply an extract from it referring to the case of Peter Schultz, an old man who has just died in a New York work-house. Peter, according to the *Traveller*, was a great tea drinker, and visitors to the almshouse encouraged his fancy by sending him many packages of his favourite leaf. Schultz was a hard drinker before he went to the almshouse, but it was of something stronger but apparently not more potent than tea. His reform and his affection for tea pleased the missionaries and good folks generally who visited him, and hence the many gifts of Oolong and Japan. But they did not know the truth. Schultz used to boil a great quantity of tea down to such a degree that the result was a potion that would have eaten away the stomach of an ordinary man. He increased the frequency and strength of his dose and soon became a tea drunkard. His nerves began to trouble and he "saw things." He was believed to have nephritis and was treated for it. One night Schultz partook of tea more liberally than usual, lit his pipe, and fell dead. At the autopsy it was discovered that his heart was fractured. It had been stimulated too much with tea and had broken under the strain. That is the plain English of it, the medical terms being left to those who deal in them. Otherwise than this fracture Schultz's body was that of a man in fine physical condition. He was a victim to his over thirst for tea. Heavy drinkers of the beverage whose nerves trouble them should learn a lesson from the experience of old Schultz. Perhaps Oolong and Japan lik more effectively than Indian and Ceylon teas; but even the latter, when boiled as Peter is supposed to have manipulated them, are not good for the constitution.

THE POSITION OF COCOA.—Cocoa is advancing in popularity, and in the import market it stands well. The *Grocer* points out that its appreciation is not confined to a single set or class of consumers of one special or isolated nationality, but extends far and near, and, after winning favours from the British population of both high and low degree, it is fast making a conquest of the palates and likings of foreign drinkers of the beverage in Eastern Europe. Especially is this so with the Germans, who have become eager patrons of this form of food of late, and are buyers of large and increasing quantities every month. No separate official returns are given of the countries abroad to which cocoa is shipped from the Port of London, so that we cannot trace from official figures its destination, or form an opinion as to which part of the Continent is the best customer for cocoa after it leaves the United Kingdom. But, in the

absence of such authoritative particulars, it may be interesting to state that statistics are prepared from private documents as to landings and deliveries of cocoa in London, and they afford some criterion of what is the extent and nature of these movements, as compared with the entries in the previous year. First, then, we may state that the total exports of cocoa from London this year up to date have amounted to 76,700 bags, in contrast with 59,700 bags in 1896, showing an increase of 17,000 bags. In addition to shipments on an extended scale, there have been clearances for home consumption also at an advanced rate, bringing the aggregate at the present time up to about 118,000 bags, against 106,000 bags in the forty-one weeks last year, which exhibits another gain in the delivery of 12,000 bags, making, with the 17,000 bags above mentioned, an augmentation of 29,000 bags in the joint deliveries of cocoa at this port during 1897. The latest official accounts, carried up to the end of September, furnish similar comparisons, stating the duty payments in the United Kingdom to be on 20,667,905 lb. in lieu of 18,443,463 lb. last year, and returning the quantity exported as 11,020,787 lb. instead of only 8,752,442 lb. in the first nine months of 1896.

KEW GARDENS AND TROPICAL PLANTS.—The "excursions of the Right Hon. Joseph Chamberlain, Secretary of State for the Colonies," are credited by the *Kew Bulletin* with being chiefly instrumental in securing for the Royal Gardens at Kew a very important extension. Kew is well supplied with accommodation for plants requiring the temperature of the stove and cool green-house, but has long wanted an "intermediate house" of larger dimensions than the conservatory. This, thanks to Mr. Chamberlain's kindly interest, has now been supplied by the erection of the new south wing of the Temperate House. It is intended to devote this wing mainly to large specimens of economic plants, such as the mango, guava, cinchona, sisal hemp, and so on. It will have largely a Mexican character, and will house a great many interesting flowering shrubs previously excluded. A new north wing about to be erected will be devoted chiefly to Himalayan plants. —*H. and C. Mail*, Oct. 29.

THE PUTUPAULA TEA ESTATES COMPANY, LIMITED.

The Annual Ordinary General Meeting of the Shareholders of this Company was held on the Nov. 10th. at the Office of Messrs. Aitken, Spence & Company, when the following report was submitted:—

DIRECTORS.—Edward Aitken, Esq., Gordon Spence Esq., W. B. Kingsbury, Esq.
SUPPLEMENT.—B. A. Tipple, Esq.

ACREAGE.			
Tea in bearing	..	391	Acres.

Grand Total .. 699 Acres.

The Directors beg to submit to the Shareholders the accounts for the year ended June 30th last.

The crop amounted to 155,593 lb. tea (against an estimate of 165,000 lb.) and 8 bushels Liberian Coffee. The net average price realised for the tea was nearly 39 cts. per lb. The Coffee sold for R67'69.

The estate suffered during the year from unavoidable change of management, Mr. Tipple having been invalided home from July to end of April; the crop was short of estimate as above; and, added to this, there was the depressed state of the tea market, aggravated by high exchange, all combining to show poor results.

R3,312'00 were spent during the year in manure which has been charged to expenditure.

R3,000'00 were spent on the 36 acres young tea clearing and have been charged to capital account.

The net profit for the year amounts to R2,960'00, and, with the balance brought forward from last year, the balance at credit of Profit and Loss Account is R7,786'94.

The Directors recommend that as no working capital was provided for at the formation of the company, and as the charge for interest during the past year was, owing to dear money, very heavy, no dividend be paid; but that the balance at disposal R7,786'94 be carried forward.

The estimate of crop for the current year is 170,000 lb. on an estimated outlay on working account of R37,280.

In terms of the Articles of Association Mr. Spence retires from the Board of Directors and offers himself for re-election.

The appointment of an Auditor for the current year will rest with the meeting.—by order of the Directors, AITKEN, SPENCE & Co., Agents and Secretaries.

OVERLAND TEA.

One by one our cherished illusions are being dispelled, our idols shattered, our preconceived notions destroyed. When the reign was young we learned as an irrevocable fact that tea coming over sea gets spoiled, and that the Russians, recognising this, refused to use the dried leaves of the aromatic and purgative shrub if they had crossed the stormy waters. There was justification for this belief, so far that the overland system has continued to this day, and caravans are now on their way from China to Russia which will travel many months and over many leagues ere the buyers get acquainted with their load. But a change has occurred in these later days—the charm has been broken, and, as might be expected, it is English enterprise which has done it. Messrs. R. M. Moir and Co. could not see any reason why China tea should not reach Russia via England and penetrate to Siberia keeping yet its original fragrance. They organised an expedition to the Obi and the Yenesei to prove their contention, and in the last week of July a little fleet left London on its reforming mission. After seven weeks' voyage, the Kara Sea was passed, and Tienman reached, and those in charge of the venture were very anxious as to how the brick tea from Hankow which had been put on board in London would show up before the *cognoscenti* gathered together to test its merits. Singular to relate, not only did the tea commend itself to the judgment of those qualified to judge, but they were even forced to admit that the condition in which it had arrived was superior to that they were accustomed to in the consignments by the all-land route. It was an eye-opener to them, as we can well imagine, to get tea in four months from Hankow which has hitherto taken six times that period to reach its destination. Moreover, this new route is incomparably cheaper. Those who go down to the sea in ships have gained another victory. The fleet has returned from its voyage laden with golden grain and jubilant at its success, and no doubt is entertained that the future Siberian demand will be met in the new way. Thus the overland tea, the pride of Russia, the erstwhile envy of the *cognoscenti* *seur*, is to become a thing of the past, and the British flag is to float over the tea imported into the dominions of the Czar of all the Russias. Moreover, the same ships which convey these "bricks" can carry the products of British Indian tea gardens, and the slow process of conversion which Russian taste is undergoing in respect of its tea be quickened, to the benefit of the colossal trade the last decade has seen built up by British capital and British industry.—*Grocers' Journal*, Oct. 23.

EXCHANGE AND PLANTING MATTERS. THE VIEWS OF A SOUTH INDIAN PLANTER.

Mr. G. L. Acworth, late chairman of the United Planters' Association of South India was last month in Ceylon having booked his passage from Colombo to Europe by the P. & O. ss.

“China which left on the 18th. Nov. He had been subjected to the interviewing process, in the course of which he expressed the opinion that his successor was mistaken in his view that the Government of India should impose an export duty of 5 per cent., being convinced that if exchange dropped to a shilling the export duty would have to be considerably higher than 5 per cent—probably 10 or 15 per cent. The difference between the actual and artificial value of the rupee meant that the planter was then really paying an export duty of 52 or 53 per cent. The Government must resume their council drawings to meet their obligations and exchange must then fall. He did not think there was the slightest possibility of the mints in India being reopened without agitation, but the West coast traders were against agitation as they were remitters and desired a high exchange, and they shipped a class of goods for which there was always a steady market which did not come into competition with other silver-using countries.

Referring to tea cultivation he said it was extending very rapidly in Travancore and the Wynaad and he hoped it would continue as he was interested in the sale of tea seed. One of the advantages of buying tea from Travancore instead of Calcutta was that they could get it at all times of the year and perfectly fresh. He had already sent to Ceylon through Mr. Cole, formerly of Ceylon, and now in Permaad, a number of leaves, and had brought a great many himself picked at random. They measured from 10 to 12½ inches in length. The parent trees from which he got his seed were about 35 years old and there was not a hybrid plant within 20 miles of where they were planted. They were raised from wild seed from Assam. In the Wynaad he expected there would be a boom in tea in two or three years. As to labour supply he believed the cry there was one of “wolf.” What however handicapped them in Southern India was the drought. As to Coorg they were beginning there this year. He added:—In Travancore my district, you must remember, is different from that Messrs. Finlay, Muir & Co. are working in. Our district was opened 40 years ago, and we are favourably off as regards roads and general conveniences, our produce being sent to Cochin, which is an excellent port where we can get direct freight home once a month, and freight *via* Bombay home twice a month. Messrs. Finlay, Muir & Co.’s district is a new one. The land was originally entered by one or two men after it had been attempted by the North Travancore Land and Plantation Company, but these few men had not means enough, and were not numerous enough to combine, and thoroughly open the district, so that Messrs. Finlay, Muir & Co. had practically a new district to develop. But they are going ahead fast, and their coning has been the greatest possible boon to the district. The place is now practically all Finlay, Muir, as they bought out the private properties, with the exception of those in the lower part of the district—particularly Mr. Knight and Baron Rosenberg, who are largely interested in cinchona, though Mr. Knight is going to open everything.

Referring to the labour question he said:—“Well our great trouble now is in recovering lost advances. There are a large number of fraudulent contractors, and the matter became so serious that we sent a special deputation to the Viceroy in 1895 and he granted a Commission

of Inquiry consisting of two Civilians and one planter to inquire into our grievance, and they wrote a very strong report in our favour, which was considered this year by our Planters’ Association, and had our very cordial approval, and it was sent to the Madras Government, and has been passed on to the Government of India, and we hope if Plague and Famine do not stop the way, the Government of India will legislate in this present session. What we principally hope for is to have registration of kanganyes. A man would have to hold a certificate as a properly authorised kangany to collect labour, and the name of this employer would be endorsed on his certificate, and we hope and have asked that the rule may be made applicable to anyone. Registration of kanganyes is the chief thing we have asked for, but there are other matters such as increased punishments for thefts of prædial products and some minor changes.

“Lastly,” said Mr. Acworth, “I should like to say a word about the healthiness of Travancore. There is a very mistaken idea that Travancore is unhealthy. It has unfortunately arisen through superintendents having gone from Ceylon to the south and got into an unhealthy tract of country. I believe in the Venture group they had many Ceylon Superintendents, and that gave Travancore a bad name, for Venture is unhealthy, and I don’t think will ever improve. I know the country well. It is one of the richest pieces of land I know, and it is all magnificent tea, but it never can be otherwise than unhealthy. It is 800 ft. high—one of those steamy hot climates where fever is always remittent. Mr. Cole was very agreeably surprised at finding how healthy Permaad was, and we have two or three Ceylon men in the hills—Mr. Bisset and young Knight and Mr. Wood, who keep their health splendidly while I have been there for 20 years, and I don’t think I am a bad specimen.”

INDIAN TEA ASSOCIATION.

INTERESTING PROCEEDINGS.

We make a few extracts of special interest to Ceylon planters from the proceedings of the Meeting held in Calcutta, Oct 12th:—

The Chairman announced that the contribution promised to the American Market Fund up to date amounted to R97,431.

Recorded telegrams from branches in Assam, Cachar, Sylhet, Dooars, Terai and Darjeeling, with crop prospects at the end of September.

The Secretary was instructed to telegraph to London, stating “prospects show little or no improvement.”

Recorded letter of 27th August, from the Secretary American Market Fund, enclosing copies of letters from Mr. Blechynden, dated 16th and 17th idem, with copies of his accounts for June and July, and pointing out that the injurious method of testing the purity or impurity of tea imported into America by means of a No. 16 sieve still prevails, and that Mr. Blechynden fears that in consequence English houses selling packet teas will be bound to do their packing in the States. Mr. Blechynden was taking active steps to have the new regulation altered, as a great injury was being done, as it was blocking the finer grades of what was known as needle leaf.

In his letter of 3rd September, Mr. Blechynden stated that he had just learned that the Japan people had made final arrangements in regard to the work they were going to do in America and he understood that they had entered into a contract to spend at the rate of \$60,000 each year in magazine and newspaper advertisements for seven years, and they had reserved \$10,000 for other purposes. He also understood that they had some hope of being able to secure a further grant from their Government after **January next for additional work.**

IMPORTANT FACTS CONCERNING CATTLE MANURE.

The November number of the *Agricultural Magazine* contains an article, entitled "Denitrification—Some important discoveries," dealing with the latest investigations of the German Agricultural Society, into the action of cattle manure, the results of which, it must be admitted, are of a startling character. Experiments carefully conducted by the leading German scientists have gone to prove that cattle manure, when used with artificial fertilizers, tends to "depress" the action of the latter. We note that the power of denitrification, or of causing a loss of nitrogen, is possessed to a great extent by the straw or litter in the manure, while the depressing action is exerted, not only upon the artificials used along with dung but even upon the nitrogen naturally present in the soil. Superphosphate of lime and kainit were found to intensify and prolong the denitrifying action, but this objectionable property tended to decrease with the age of the manure and with long contact with the soil, while such substances as sulphuric acid and copper sulphate have the effect of minimizing denitrification.

All these results, it must be confessed, open out new questions with regard to the use of manures, the forms they should take and their method of application.

The first idea that strikes us with reference to this question is that to defeat the denitrifying power we should apply cattle manure and artificials separately and at different periods, due time being given for the dung to lose the power of bringing about a dissipation of the nitrogen of artificial fertilizers. But the subject is altogether too complex to be disposed of by any offhand suggestion, and there is little doubt, considering the far-reaching results of the German investigations referred to—not only to the agriculturist but to the manure merchant—that English scientists will thoroughly thrash out the subject before long. It would be interesting to enquire whether the denitrifying power of dung also extends to or is exerted upon such organic fertilizers as castor cake, blood meal and fish manure, while we should be glad to know whether any of our tropical agriculturists have been struck by what is termed the "depressing action" of cattle manure when used in combination with the more concentrated fertilizers commonly in use in the tropics. We would draw attention to the article in question in the *Agricultural Magazine*, which we may mention is given as a Supplement to the *Tropical Agriculturist*.

COFFEE IN THE STRAITS.

Mr. W. W. Bailey writes some pungent comments in the *Straits Times* upon the careless way coffee is pulped in the Native States. As the matter is of great importance to our own coffee growers, we quote a portion of his remarks:—On the cherry loft, I saw a lot of cherry which had been picked several days without having been pulped, though, in the old coffee days in Ceylon, one would have been in a great state of mind if any had to be left over even to the next day. 10 per cent. of the cherry was immature and the beans of such cherry are bound to shrivel in drying, and not turn out a good glossy sample (and I imagine it is more likely to go bad in transport). I remarked at the time that it was a very good sample of cherry. From the cherry loft, I went to the pulper, which was sending some 40 per cent. of pulp into the receiving cistern, we have not yet got a pulper which can do anything approaching good work in separating the cherry from the bean, no matter how well set it is; however, I think one will soon appear which I have seen do really good work.

From the pulper I went on to the receiving and fermenting cistern, and there I got a shovel and turned up some of the parchment which was being fermented. The stench was something horrible from enormous

percentage of pulp being fermented with the parchment; when I was looking at it, I said to myself, "No wonder our coffee is getting a bad name in the market." This treatment does not much interfere with the appearance of the coffee when it has been pulped, polished, and made ready for market; but I am absolutely certain that it must give the coffee a bad sour taste. I consider this fermenting of the parchment with the pulp the worst of all the evils I have mentioned, and the simple and cheap remedy for it is as follows:—

Pulp into the washing cistern, in which have two men washing and separating the pulp from the parchment, and this can be done to the large extent of 90 per cent: throw the pulp (which still contains a little parchment) alongside the cistern to be washed again the next day to get the rest of the parchment out, and the parchment into the fermenting cistern (it will then be minus 90 per cent. of the pulp it first had). If any one should say that this is expensive, I am prepared to prove that the curing per picul of clean coffee on the estate on which it is done is about the cheapest curing done in the Peninsula. On looking over the sides of the fermenting cisterns; I saw flakes of nasty, sour, half-dry saccharine matter, and at the bottom in a pool at one end was some white looking stuff, which smelled very much like bad bread barm that had a dead rat in it for some days, and this horrible stuff, I know, is left there until the next lot of coffee is put in to be fermented and get its flavour; whereas with the water turned on for 5 minutes one man with a brush would make it as sweet as a nut.

I would not write the above if I did not realize that the planters have to do something to produce a better sample of Liberian coffee than they now produce, and I know they can produce one very much better at a cost of less than 60 cents per picul of clean coffee.

I am a strong supporter of doing something; but I do not think that the planters should look for any direct profit out of it, and I think that a travelling agent in America would be more likely to advertise our coffee than a place of business in London: but, before we had advertise our coffee better see and turn out a better sample than the present one.—*British North Borneo Herald*.

CURING VANILLA BY THE CALCIUM CHLORIDE PROCESS.

The cultivation of vanilla is the largest secondary industry in the French colony of Reunion, near our own possession of Mauritius. Indeed, the profits yielded by it have more than once helped the farmers in the island to tide over a bad sugar season, although on an average the value of the vanilla production is only one-third of the 500,000*l.* which represents the sugar output. A great deal of the Reunion (or Bourbon, as it is often called) vanilla is consigned to London, and passes through our drug-auctions. About two seasons ago attention was called in the sales to some packages of Reunion vanilla which had just been received as having been "dried by a new process," but no information was given wherein that new process differed from the old. We were afterwards enabled (see *C. and D.*, September 12th, 1896) to give a short outline of the process, which consists, in the main, in the substitution of calcium-chloride as a drying-agent for the free air or hot-air stove formerly relied upon.

Consul C. W. Bennett, in a recent report, gives further particulars of the calcium chloride process, which appears to have thoroughly established itself in the island by this time. The preliminary treatment of the fruit is the same as that of the older method. The pods should be picked as soon as their lower portion begins to turn yellow. If picked too green their aroma does not fully develop; if too ripe they will split in the drying, which lowers

their commercial value. Within twenty-four hours after gathering the pods should be dried in tins not too large to prevent all the vanilla from being heated evenly; old petroleum-tins do very well. The tin is lined all through with wool, a quantity of vanilla-pods placed vertically at the bottom, and a horizontal layer laid on the top of the first one. A number of tins are then put in a halved wine-barrel, and hot water poured into the barrel up to the lid of the box; but no water must penetrate it. The barrel is covered with a piece of sacking and left overnight. The pods are then taken out, dried for a while in the air, and then indirectly exposed to sunlight, covered with a woollen cloth, and spread on shallow wooden boxes placed upon trestles. This first drying generally takes two or three days, and is completed when the pods have acquired uniformity of colour.

At this point the calcium-chloride process comes into operation. This is carried on in a galvanised-iron box, 40 inches long and broad, provided with a hinged door with indiarubber edging—airtightness being a necessary condition for the success of the process.

The apparatus, as will be seen, is the same in construction as an ordinary hot-air chamber. The sliding hurdle frames rest on side brackets, a calcium-chloride tray being placed in the centre, and at the bottom. The vanilla-frames should not be made of resinous wood; split rattan is the best. The calcium-chloride vessels should be double-bottomed, the upper bottom being perforated, in order to allow the liquid (CaCl_2 is extremely deliquescent) to escape. As a rule, the process of drying takes from twenty-five to thirty days. The box should be opened every two or three days, and all mouldy pods removed. The usual charge for a whole box is 40 lb. of calcium chloride and 100 lb. of vanilla-pods. Any mouldy pods removed during the process of drying should be sunned, collected, and dried in a separate box.

When sufficiently dried, the vanilla-pods are exposed on small frames for several days in a covered and well-ventilated place, and then put in tins holding from 30 to 50 lb. each. The pods are kept in these tins for several weeks, well closed, and are examined every few days, all pods showing traces of mildew being carefully wiped. When the pods appear to have reached full perfection of aroma the last stage but one in the treatment is reached. It consists in washing the pods in a receptacle containing clean water of a temperature of 60°C . (140°F). About three pints of water should be used for every pound of vanilla-pods, and the pods well stirred by hand during the washing-process. They are then lightly wiped and put to dry in the shade. In a few days they are ready for sorting according to length and quality, bundling, and boxing. Vanilla ought not to be shipped until at least a month after being boxed. Every few days it should be examined, and all pods showing traces of moisture removed.

The action of calcium chloride is of course due to the avidity with which it absorbs moisture. The advantages of the calcium-chloride process are that the loss of aroma almost inseparable from the old curing-processes is avoided, and that there is a great saving of hand-labour (which, in Réunion, costs about 1s 6d a day). Vanilla has realised very high prices recently, and its culture is extending in various parts of the Tropics. In Réunion there is now hardly a sugar estate which has not more or less land under vanilla. Many large planters cultivate nothing but vanilla, and in the parishes of Ste. Rose, St. Philippe, and St. Joseph the little plots of ground round the huts are covered with vanilla-creepers. When the pods are ripe they are sold green to neighbouring merchant, realising quite a small fortune for the grower. The only drawback to the crop is that it gives rise to a great deal of theft. Many small fortunes have been made by illicit vanilla buyers, but the detection of the culprits is almost as difficult as that of diamond-thieves at the mines.—*Chemist and dyer, Oct. 30.*

COCA (*ERYTHROXYLON COCA*, LA M

BY J. F. BAILEY.

CULTIVATION.—The Coca is cultivated very largely in the Andes of Peru, Bolivia, Columbia (especially in the very moist mild climate met with at from 2,000 to 5,000 feet above sea-level), parts of Brazil, and many other countries of South America. The plants are propagated from seed, which should be sown as soon after gathering as possible (as like many other seeds in this climate, they do not keep well), in a plantation set apart for the purpose. When the seedlings are about six inches high they may be transplanted to their permanent situations.

COLLECTION, PREPARATION, ETC.—Great care must be taken in the gathering, drying and preservation of coca, as its activity and value depend in a great measure on its mode of preparation. The leaves should be gathered as soon as they have arrived at maturity, at which period they are bright-green on the upper surface and yellowish-green on their under surface, and have an agreeable and somewhat aromatic odour. The leaves are gathered separately and carefully by hand with the twofold object by preventing them being crushed or bruised in the process; and also so as not to injure the young leaf buds which are left behind for the purpose of obtaining a second crop of leaves. They are then spread out and dried slowly in the sun. This operation must be performed with great care, for if the leaves be dried too rapidly, they lose their odour and green colour; and if stored away before they are thoroughly dried their colour is also changed, and they acquire a disagreeable odour and taste.—*Queensland Agricultural Journal* for October 1897.

PLANTING NOTES.

EUCALYPTUS OIL.—The trust in the therapeutical efficiency of this oil has passed its zenith and is evidently much on the decline. Most of the oil is still coming from Australia whose total export of the various eucalyptus oils amounted to the value of £5181 in 1895. As the average value per pound is about 1s 6d this amount represents about 69,080 lb. of oil. Algeria is still producing considerable amounts of oil; however, it cannot successfully compete with Australia. More recently the distillation of eucalyptus oil has also been introduced into Northern Portugal. The leaves used are from *Eucalyptus globulus* La Billardiere and *Eucalyptus resinifera* Smith. The latter species is remarkable for its rapid growth; the oil obtained from the same consists mainly of a hydrocarbon of turpentine oil odor, so that it hardly will meet with much favor. We expect soon to receive samples of the oils of both species for estimation.—*Schimmel & Co.'s Report.*

LEMONGRASS OIL.—The shipments from the coasts of Malabar have been considerably greater than those stated in our last Report. They amounted to:—

Season of	1891/92	1450 cases.
" "	1892/93	1863 "
" "	1893/94	2332 "
" "	1894/95	2370 "
" "	1895/96	3079 "
" "	1896/97	3000 "

These figures show that the production keeps in a close ratio with the increased consumption. Each original case contains 12 wine bottles filled with oil. Small instalments of oil of inferior quality are regularly shipped from Ceylon, but the production of this oil seems to be constantly on the decrease in Ceylon as is to be seen from the blue-books of the Straits-Settlements, while that of oil of citronella is very considerable. The demand for lemongrass oil was brisk and most of the recent crop has been sold in advance and for delivery in fall. We are booked for 500 cases. In consequence of this demand, the prices have advanced from 2d per lb. to 2½d, and may go still higher during the time of delivery and use.—*Schimmel & Co.'s Report.*

THE LANKA PLANTATIONS COMPANY, LIMITED.

DIRECTORS.—George Allen, Esq. (Chairman), William Austin, Esq., Henry Bois, Esq., Edward Pettit, Esq.

AGENTS IN COLOMBO.—Messrs. J. M. Robertson & Co. SECRETARY.—Mr. Charles M. Robertson.

The following is a copy of the report presented at the seventeenth ordinary general meeting of the Lanka Plantations Company, Limited, held at the office of the Company, on Wednesday, the 17th November, 1897, at twelve o'clock noon precisely.

1. The Directors now submit their report for the twelve months ending 30th June last, together with the balance sheet and accounts of the Company made up to that date and duly audited.

2. The coffee crop shipped to London was 572 cwt., against 605 cwt. last year and realized £2,688 15s. 8d. net. The acreage under coffee alone is nominally 187 acres.

3. The total crop of cocoa gathered on Yattawatte amounted to 1,272 cwt., against 1,355 cwt. last year, and realised £3,735 8s. 4d. During the season 46 acres were planted with cocoa, 24 acres of which have been interlined with liberian coffee, and 58 acres of available land adjoining the estate have been purchased, making a total of 250 acres new land. The cost of the land and the new planting are charged to capital cocannt.

4. The tea received from the Company's estates amounted to 701,112 lb. and has been sold at an average of 7-53d. per lb. net, realizing £22,002 8s. 4d. Last year the Company received 646,161 lb. which was sold at an average of 8-15d. per lb. net, and realized £21,967 10s. 2d. The cost of production has, however, been increased by the rise in the sterling value of the rupee, consequent upon the closing of the Indian Mints, and by loss on the sale to the coolies of imported rice, owing to the famine in India. A fully equipped factory has been erected on the Rillamulle Estate, and the cost charged to capital account.

5. The following statement shows the acreage and state of cultivation of the Company's estates on the 30th June last:—

Estate.	Coffee.	Tea.	Cocoa.	Grass.	China and Patcha.	Forest and Timber Trees.	Total.
Ampittia-kande, and Arnhall ..	50	414	..	4	167	70	705
Fruit Hill Fordyce, Garhawn, Gona-galla and Paramatta	227	10	..	237
Rappahannock	784	..	17	..	185	936
Rillamulle	322	..	31	30½	90	473¾
Thotulagalla	232	6	20	258
Yattawatte	235	..	4	83	96	555
	*717	95	503	82	1,197
	187	2214	717	151	599½	493	4361¾

* 63 acres interlined with liberian coffee.

6. The net profits for the past year amounted to £8,281 0s. 4d., to which must be added the sum £2,060 7s. 11d. the balance brought forward from the year 1895-6, making together £10,341 8s. 3d.

7. Having already paid a half-year's interim dividend on the six per cent. Preference shares to the 31st December, 1896, amounting, less property tax, to £426 6s. 0d., the Directors recommend payment of the dividend on these shares to the 30th June last requiring, less property tax, a similar amount, and having deducted £1,493 8s. 0d., being one-tenth of the sums charged to suspense account during the 10 years ending 30th June, 1896, they further recommend a dividend of 10/- per share, being 5 per cent. free of income tax on the ordinary shares amounting to £7,500, carrying forward a balance of £495 8s. 3d. to the next account.

8. The Directors who retire on this occasion are Mr. George Allen and Mr. Edward Pettit, who being eligible offer themselves for re-election.

9. Mr. John Smith, the Auditor, also retires, and being a shareholder offers himself for re-election, —By order. C. M. ROBERTSON, Secretary.

12, Fenchurch street, London, E.C., 5th November, 1897.

THE KANAN DEVAN HILLS PRODUCE COMPANY, LIMITED.

NEW ISSUE OF SHARES.

CAPITAL ... £1,000,000.

DIVIDED INTO

25,000 Six per cent. cumulative preference shares of £10 each.

75,000 Ordinary shares of £10 each.

(Of which £500,000 of ordinary shares have already been issued to the Consolidated Tea and Lands Company, Limited, and the Amalgamated Tea Estates Company, Limited.)

PRESENT ISSUE—

10,000 Six per cent. cumulative preference shares of £10 each.

15,000 Ordinary shares of £10 each.

DIRECTORS.

Sir John Muir, Bart., of Deanston; and of Messrs. James Finlay & Co., 22 West Nile street, Glasgow, and 34 Leadenhall street, London; and of Messrs. Finlay, Muir, & Co., Calcutta and Colombo —Chairman. Sir Robert Drummond Moncreiffe, Bart., of Moncreiffe, Bridge of Earn, Perthshire. P. R. Buchanan, Esq., of Darleith, Cardross. William Allan Coats, Esq., Director of Messrs. J. & P. Coats, Limited, Thread Manufacturing, Paisley.

A. B. Murray, Esq., 33 Renfield Street, Glasgow, and Rosebank, Partick; A. M. Brown, Esq., of Messrs. James Finlay & Co., 22 West Nile Street, Glasgow; William Walker, Esq., of Messrs. James Finlay & Co., 22 West Nile Street, Glasgow; Robert Scott, Esq., of Messrs. Morgan & Scott, 12 Paternoster Buildings, London; R. H. Sinclair, Esq., 19 Kelvinside Terrace, Glasgow.

PROSPECTUS.

This Company was formed in May, 1897, for the purpose of acquiring and developing the lands and estates which originally belonged to the North Travancore Land Planting and Agricultural Society, Limited, particularised in section A of the accompanying schedule. The purchase price was fixed by Mr. W. Milne and Mr. L. Davidson, as follows:—

Value of Land, .. £102,775
Value of Estates, .. 43,750

£146,525

The purchase price has been paid, possession has been given, and the transfer of the property to the Company is in course of completion.

Since its formation, the Company has succeeded in securing the following further and adjoining lands and estates:—

The property of the Aneimudi Tea Company, Ltd.,	R159,600	
The property of the Toliar Valley Planting Coman.Ltd.	70,000	
The property of the Chittavarrai Planting Company Ltd.	7,000	
The Benmore Estate, ..	38,000	
The Cuddalaralle Estate ..	30,565	
The Kanniamallai Estate..	100,000	
The Hanbath Estate ..	29,000	
The Peria-Kanal Estate ..	37,500	
The Puli-Vassel Estate ..	25,000	
	<u>R496,665</u>	
	exchange, say 1/3=	£31,041 11 3
The Parvithi Estates, ..		8,500 0 0
The Vagavarrai Group of Estates, &c., ..		19,000 0 0
		<u>£58,541 11 3</u>

Particulars of these are given in section B of the accompanying schedule.

The Directors have also recently purchased—

The Estates of the Noakcharee Tea Company, Limited, Assam for ..	£100,000
The Lynsted Estate, Bogawantalawa, Ceylon	30,000
The Maddegedera Estate, Kalutara, Ceylon	35,000
	<u>R165,000</u>

Particulars of the last-named Estates are given in Section C of the accompanying Schedule.

In regard to these last three purchases (Section C), it may be explained that the Directors thought it desirable to secure the property of the Noakcharee Tea Company, as, in their opinion, a combination of good Assam estates with high country estates, such as the Company's property in the Kanan Devan Hills, North Travancore, will secure the most permanently successful results. In addition to this, the Directors considered it, as a favourable opportunity offered, advisable to secure some estates capable of earning a dividend on the whole paid up capital during the period in which the Company's lands and young estates in North Travancore were being opened up and developed.

To complete the purchase of the properties named in Sections B and C, and to develop the same, some additional capital is required, and the Directors have accordingly resolved to make a new issue of £250,000, viz. :—

10,000 six per cent. cumulative Preference shares of £10 each,	£100,000
15,000 ordinary shares of £10 each,	150,000
	<u>£250,000</u>

all of which are now offered for subscription to the Shareholders of the Consolidated Tea and Lands Company, Limited, to the Shareholders of the Amalgamated Tea Estates Company, Limited, and also to the employes of the Kanan Devan Hills Produce Company, Limited.

The Directors are of opinion that it is to the benefit of the Company to encourage the Managers, Superintendents, and Assistants (on whose work so much depends) to become Shareholders. They also think it fair that the Shareholders of The Consolidated Tea and Lands Company and of The Amalgamated Tea Estates Company, who as such Shareholders are now so largely interested in The Kanan Devan Hills Produce Company, should have an opportunity of becoming personally interested in it if they so desire. As, however, it is essential that this Company should, during the period of its development, be worked as a private Limited Company, Shares will only be allotted to those who desire an investment. The Company will be worked on some-

what similar lines to those on which The North and South Sylhet Tea Companies were so successfully conducted. * * *

With the addition of the new purchases, the Company possesses :—

	Uncultivated Land.	Tea.	Coffee	Cin- chona	Total acres.
In Travancore,	92,200	2,131	606	926	95,863
In Assam,	10,326	2,442	—	—	12,768
In Ceylon,	141	778	—	—	919
	<u>102,667</u>	<u>5,351</u>	<u>606</u>	<u>926</u>	<u>109,550</u>

TRAVANCORE.—A considerable proportion of the land in Travancore is of the very finest description, and is capable of yielding large crops of fine quality tea, and also coffee. It will be seen that there are 2.131 acres of tea, 606 acres of coffee, and 926 acres of cinchona, at present under cultivation. With the exception of the cinchona, and 515 acres of tea and coffee in bearing, the whole of this area consists of young tea and coffee, principally planted in 1894, 1895, and 1896, which will not yield much crop for two years. A further area of 2,000 acres of tea and 300 acres of coffee is being brought under cultivation in 1897. The whole of the Company's land in Travancore under tea cultivation is at an elevation of from 4,000 to 6,000 feet above sea level, and it is estimated that there are still 16,000 acres of forest and good grass land at a similar elevation, and suitable in every respect for the profitable growth of good quality tea and coffee. The lands at a lower elevation are also very rich, capable of producing large crops of coffee and medium tea, and suitable, it is believed, for the growth of rubber. To the last-named industry the Directors proposes to turn their special attention. Important roads are in course of construction on the Company's Travancore property, to connect it with the east and west coasts, and these will greatly add to the value of the lands. There is a large permanent Coolie force, and labour is easily procurable. There is a good staff of European Managers and Assistants, under the supervision of Mr. W. Milne, the Resident Superintendent. It is proposed to extend as rapidly as possible the cultivation of high-grown tea as well as coffee and rubber in Travancore.

ASSAM.—The estates of the Noakcharee Tea Company, now acquired by the Company, are very valuable. They are situated in the district of Jorehant, Sibsagar, Assam, a locality of proved excellence in the production of high quality tea. There are 2,300 acres of tea in bearing, which are estimated to yield a profit of £7,000 per annum. But the feature which makes the purchase more particularly attractive is the possession of 7,600 acres of valuable freehold forest land, which will be rapidly developed.

Mr. Mann, the Visiting Agent for The Consolidated Tea and Lands Company, Limited, places the value of the whole property at £116,000, and the Directors succeeded in securing it on behalf of the Company for £100,000. In writing of this land, Mr. Mann remarks :—"The forest land is very valuable. If extensions are contemplated on a large scale, and at no distant date, the jungle forest would not be prohibitive, even if valued at R150 per acre, which would raise the value another £24,000. It must be borne in mind that this property is all practically freehold, which is now scarcely to be had in Assam. What still remains to be opened up is well timbered, and, were it now taken up under Government lease, there would be, at least, R80 per acre demanded by Government on account of Timber."

There is always a good demand for good Assam teas, which are in comparatively limited supply.

CEYLON.—The Lynsted Estate is a first-class high country estate, and is estimated by Mr. F. W. Clements, Visiting Agent, Ceylon, to yield a profit of £2,870 per annum.

The Maddegedera Estate is a specially attractive low country property, and is estimated by Mr. L. Davidson, Visiting Agent, Ceylon, to yield a profit of £3,200 per annum. Taking the profits of 1897 and 1898 of the bearing area in Travancore at £2,000,

the profits of the Company for those two years from all sources should be about £15,000 per annum, which will provide a satisfactory dividend on the called up capital. A large increase of profit may reasonably be expected when the young cultivation in Travancore comes into bearing. This point should be reached in 1899. The encouraging prospects of this Company will be immediately recognised from the fact that it possesses a total area of 100,000 acres or thereabouts of land, which, as will be seen from the Schedule, is practically Freehold, and a considerable portion of which is exceptionally rich, and suitable for the growth of tea, coffee, and other Eastern products.

THE SCOTCH TRUST AND LOAN COMPANY OF CEYLON, LTD.

Capital	£250,000
First issue (fully subscribed) ..	£150,000
Of which paid up	£45,000
Reserve Fund	£10,000

DIRECTORS.—James Haldane, Esq., C.A., Edinburgh John Wilson, Esq., of Messrs. Honeyman & Wilson, Edinburgh; Henry Johnston, Esq., Q.C., Advocate Edinburgh; and J. H. Beilby, Esq., 10, Clarendon Crescent, Edinburgh.

SECRETARY.—Francis A. Bringlee, C.A., 123 George Street, Edinburgh.

The following is the report by the Directors of the Scottish Trust and Loan Company of Ceylon, Ltd., to the Twentieth ordinary general meeting of shareholders, held within the Company's Registered Office, No. 123 George Street, Edinburgh, on Wednesday, the 27th of October. The Directors present their Twentieth Report, being for the year to 31st August, 1897.

ESTATES IN THE COMPANY'S POSSESSION.—The yield of tea from the estates continues satisfactory, both the crop and the net proceeds having been in excess of those of last year. The adverse factors during the past season have been the rate of exchange, the enhanced cost of rice, and a slight fall in the price of tea.

The coffee crop was slightly shorter than last year, but better prices made it equal in value. This product will be coming forward in diminished quantity, and the fields are by degrees being planted up in tea. The new clearings are well advanced, and further small extensions will be made during the coming season.

FACTORIES, BUILDINGS AND MACHINERY.—Special attention has been devoted to these. The machinery is in efficient working order, and the buildings are maintained in thorough repair. The New Factory on Sarnia is almost finished and forms a valuable addition to that estate; it has, however, cost more than was originally expected.

The Directors have pleasure in recording their appreciation of the work of the staff in Ceylon, who have been successful in arranging their labour supply to suit the needs of the estates, with only a moderate increase in the advances to coolies.

MORTGAGES HELD IN CEYLON BY THE COMPANY.—The loans have been increased during the year by the sum of £1,600 in a further purchase of Terminable debentures of the Tonacombe Estates Company of Ceylon, Limited, bearing interest at 6 per cent. A loan of £9,000 over Lawrence estate is to be repaid in November, and the proceeds will be applied in meeting debentures maturing at Martinmas, and in reducing the temporary advance from the Company's bankers.

DEBENTURE DEBT.—The debentures have been reduced by £2,300 during the year, and the directors propose to pay off at Martinmas the sum of £3,600 falling due at that term.

As the Company's debentures have now been practically redeemed, the directors propose, in response to a very generally expressed feeling among the shareholders, to take the necessary steps to reduce the liability on the Company's shares by writing off £5

per share of uncalled capital, thus making the shares £5 shares, with £3 paid. Before the Company can proceed to the matter of reduction of capital, it is necessary to alter the Articles of Association of the Company. The necessary motion to that effect will be submitted to an extraordinary general meeting to be held after the close of the Company's annual general meeting.

ACCOUNTS.—The balance at the credit of profit and loss account is £8,395 12 0

And the Directors propose—

To pay a dividend of 5 per cent per annum, free of Income Tax £2,250 0 0

Note.—Two and a half per cent of this was paid as an Interim dividend at Whitsunday 1897.

And a Bonus of 7½ per cent free of Income Tax £3,375 0 0 £5,625 0 0

Thus leaving £2,770 12 0 to be carried forward to the next account.

The directors desire to record an expression of their regret at the loss they and the Company have sustained by the death in December last of their valued colleague. Mr. Thomas Dickson, who, from the inception of the Company in 1878, occupied the important post of Managing Director, and since 1880 that also of the Company's Agent in London. The directors have appointed Mr. W. Bowden Smith of Colombo, who will shortly be resident in London as Agent there, in place of Mr. Dickson, and Mr. A. Gordon Dickson as Assistant Agent. Until Mr. Bowden Smith's return from Ceylon, the duties of London Agent are being discharged by Mr. W. Herbert Anderson. The late Mr. Dickson was, in ordinary course, the retiring director, but the Board do not recommend that the vacancy caused by his death be filled up.

The Auditor for the current year falls to be appointed.—By order of the Board.

FRANCIS A. BRINGLEE, Secretary.

EDINBURGH, 19th October, 1897.

PLANTING NOTES.

COCONUTS AND PADDY AT THE STRAITS.—The District Officer, Kuala Selangor (Mr. A. Hale), reports:—

A customary holder refused \$200 for an acre of coconut trees, half in bearing, half too old or too young, at Jeram. I assessed a lot of land at Dungun for Jeram people, who want to extend their coconut plantations.

The District Officer, Ulu Selangor (Mr. R. C. Grey), reports:—

The most important event of the month was the receipt of an application from Towkay Loke Yew for some thirty-two square miles of country in the Ulu Bernam district for the purpose of padi-planting. The Towkay came to see me on the subject on the 9th, and we then discussed some of the details of his scheme. He intends to import an army of Chinese agriculturists, and he and his partners in the enterprise are prepared to spend a large sum of money in irrigation. I have not yet visited the place as Towkay Loke Yew has not been able to accompany me, but as soon as we have had an opportunity of seeing the country I shall be in a position to report more fully on the matter. In the meantime the scheme seems so commendable that I think every possible assist ance should be given to the Towkay. The greatest difficulty with which miners, and probably also planters, have at present to contend, is the high price of rice, and the most pressing want of the time is that rice planting should be undertaken on a really large scale. For these reasons the initiation of a scheme of this sort should rank among the most important events of the history of the Native States. If the price of rice in the country were definitely reduced, labour would become cheaper, and probably more plentiful.

SCIENTIFIC PLANTING.—Dr. Leather, Agricultural Chemist to the Government of India, has addressed the planters of Northern India through their representative body, the I. T. A., stating that his engagement was about to terminate, and enquiring whether it would be worth his while to commence practice as an Agricultural Chemist in connection with Tea, Indigo, &c. Unluckily, sufficient inducement could not be offered him at the present time, as there is “practically no work for an Agricultural Chemist.” No work indeed! Rather should it be said that the necessity for such work is not recognised. Madras the Benighted will soon, we hope, give North India a lead, and a long one, in this matter.—*Ibid.*

TEA PLANTING IN REUNION: A POSSIBLE OPENING FOR A CEYLON MAN.—A Reunion sugar planter—whose name (Scottish) is not unknown in the past banking and surveying annals of Ceylon—is anxious to have tea tried in his neighbourhood. Writing to a relative acquainted with Ceylon he says:—

“Can you give me some good information as to the culture and manipulation of tea as it is cultivated in Ceylon; above all as to the price of labour. You will render me a service because here in Reunion tea grows admirably and is of very good quality, and I think if we could meet with an Englishman who would come to try it here, he would be well received by my family and neighbours, because you know our land is, as in Ceylon, 5,000 feet high and even more. If you know any one who would come and see for himself I would receive him with pleasure and show him much suitable country for growing tea.”

We learn that the writer's place is easily got at being about three hours' journey from where the steamers from Mauritius land, and it is only 14 hours from Mauritius. The climate is delightful; but the doubt will be as to a sufficiency of labour for tea culture. Any one interested can have the address on application.

TEA IN JAVA.—Mr. J. H. S. Davidson, who went to Java some four months ago, in the interests of the firm of Messrs. Davidson & Co., has returned to Colombo with a very good impression of tea growing prospects there. He says that, though tea has been grown for a long time past in Java, the success of the place as a tea growing country undoubtedly lies in the future. Enormous tracts of land are being opened up, and there is a great demand for the newest kind of machinery. Mr. Davidson has had good opportunities of seeing tea cultivation in India, Ceylon, and Natal, and he says, he never saw a place better fitted for the industry than Java. From what he could see the soil is excellent and there is very little trouble in regard to labour. It is all Malay labour, of course, and it is free; that is to say there is no such thing as coast advances. He was also much struck with the facilities for travelling in Java. The gradients are not so steep as in Ceylon and he says that, besides a railway which runs into the heart of the tea-growing district, they have remarkably good roads. A kind of tea they go in for there to some extent is known as “white tips.” It is a very delicate, light liquoring tea made without fermentation. He only met two English planters in Java, but both were doing well. One is Mr. Bingley, who was in Ceylon for a time, and the other Mr. Evans. Mr. Bingley has with him Mr. Adams, who went out from Ceylon at the recommendation of Mr. Wright not very long ago. According to Mr. Davidson, when all the newly opened estates in Java come into bearing, it will make an appreciable difference on the tea market.

CINNAMON OIL, CEYLON.—The result of the last cinnamon auction, which took place on May 3rd, was not as satisfactory as the preceding ones. Only about one-half of the bark offered was sold and prices declined by about 3d to 1d per lb. The prices realized for both commodities, bark and chips, seem to be profitable to the planters; and for the issue of the 2nd of August of the “Tropical Agriculturist” published in Colombo contains an urgent warning against the contemplated extension of cinnamon plantations, correctly arguing that the consequence would be over-production and low prices.—*Schimmel & Co.'s Report.*

“THE AGRICULTURAL GAZETTE” of New South Wales, issued by direction of the Hon. Sydney Smith, M.P., Secretary for Mines and Agriculture. Vol. VIII. Part 9. Edited by W. H. Clarke. The following are the contents for September 1879:—Useful Australian Plants, J. H. Maiden; No. 43—*Tripholis micradon*, Benth; No. 44—The Reflexed Panic Grass (*Panicum reversum*, F.v.M.); Botanical Notes—Note on two so-called Madagascar Beans—No. 1.—A variety of the Lima or Duffin Bean (*Phaseolus lunatus*, Linn.; var. *inamamus*); No. 2.—The Lablab or Sim Bean of India (*Dolichos lablab* syn. *Lablab vulgaris*). Weed eradication on a Canadian Railway. A note on the Lulla or French Honeysuckle (*Aledysarum coronarium*); Melanose of the Orange—Results of Experiments at Castle Hill, G. B. Owen; Agricultural Education, F. B. Gutbrie; Plant Diseases and Legislation, B. T. Galloway; New Labour saving Implements, J. L. Thompson; Influence of Bees on Crops, Albert Gale; Profitable Poultry Breeding for the Local and London Markets, Geo. Bradshaw; The Keeping of Grapes, P. Monillefert; Rules for Tuberculin Test issued by Board of Health; Trees for Shelter and Break-winds, H. V. Jackson; Bee Calendar for October, Albert Gale; Orchard Notes for October, George Waters; Practical Vegetable and Flower Growing for October, W. S. Campbell; General Notes; Replies to Correspondents; List of Agricultural Societies' Shows; Label for Specimens.

PETER LUND SIMMONDS, F.L.S.—The Society has lost an old and well-known member by the death of Mr. P. L. Simmonds, on the 3rd October. Mr. Simmonds' real name was Lund. He was born at Aarhuus, Denmark in 1814, and was adopted by Lieutenant George Simmonds, R.N., whose name he took. Mr. Simmonds was a voluminous writer on technical and commercial subjects. In 1853 he published a volume on “The Commercial Products of the Vegetable Kingdom,” and from that date, until within a few years of his death, he continued to produce a constant succession of books, which, if they were sometimes deficient in minute accuracy, were always full of useful information. Perhaps his best known works were “Waste Products and Undeveloped Substances,” 1862, and “Tropical Agriculture,” 1877. He became a member of the Society of Arts in 1855, and in 1862 he was elected a life member, without payment, in recognition of the work he had done for the Society, and his services in the application of sciences to the arts. His contributions to the *Journal* have been very numerous, and include a great deal which does not bear his name. He read no less than sixteen papers before the Society on a variety of subjects. In spite of his constant and laborious work he was never prosperous, and as advancing age rendered him incapable of the journalistic work which formed his main support, he fell into pecuniary difficulties. About five years ago some of his friends were successful in obtaining for him admission to the Charterhouse, a refuge which few can have better deserved. His end was hastened by an unfortunate accident. About a fortnight before his death he was knocked down and run over by an omnibus in the Gray's-inn-road, the result of which was that one leg was fractured and he received scalp wounds on the back of the head and forehead of a serious character. He was buried on the 7th October, in the Charterhouse burying ground, Bow Cemetery, after a funeral service in the chapel of the Charterhouse.—*Journal of the Society of Arts,*

JARRAH WOOD FOR CEYLON.

Amongst the many passengers on their way from England to Australia by the O.R.M.S. "Orotava," is Mr. William Traylen, J.P. of Guildford, Western Australia, who is travelling between Australia and England for the sixth time within eighteen months and six times he has landed at Colombo. Mr. Traylen is an ex-member of the Legislative Assembly of Western Anstralia and while in the house occupied the responsible position of Chairman of Committees. He is much interested in the introduction into Ceylon and India of Jarrah wood, the principal indigenous timber of Western Australia, and has been the means of bringing to Ceylon specimens of the timber for the purpose of making a definite trial with them. One of these—a pile 35 feet in length—he is offering through Messrs. Whittall & Co., to the Colombo Harbour Works with the view of it being employed (as a test of its staying capacities) in the new breakwater: other timber he is offering to the Public Works Department with the view of it being used as railway sleepers on the Ceylon Government Railways: further specimens deposited with Messrs. Whittall & Co. are to prove the superiority of the wood for other purposes, especially as shingles, for the roofing of bungalows, etc. Though more costly, Mr. Traylen claims that the Jarrah shingles would prove far more economical in the long run than the country-grown ones now in use. Further, the wood resists the attack of white ants and the terredo in the tropics, and so far as marine purposes is concerned it is not affected seriously by the attacks of the chilura. In one respect at any rate Jarrah is a reversal of the English oak, inasmuch as the best timber is on the outside.

"I believe," said Mr. Traylen, to our representative, "you will be well satisfied with its life, and in years to come you will find it work out cheaper than teak. At present I have no idea what you pay in Ceylon for Moulmein teak, but I understand that it is getting scarcer and dearer."

"And what," asked our representative, "is the price you ask for Jarrah?"

"We ask £3 10s. per load of fifty cubic feet in Western Australia. There we use the wood for every thing, but what interests you most, is that it is very largely used for marine work and for railway sleepers. For the latter purpose I think I can fairly say no other wood is now used by us. Messrs. Whittall & Co. have specimens of Jarrah, which have been used for thirty years in the water and you can see how it stands everything. Remember you must have well grown Jarrah. Here is what Mr. Ednie Brown, our Conservator of Forests, says:—

In all cases, this tree delights in an ironstone formation, and it would almost appear as though the rougher and the more the site is composed of ironstone rocks and barren of almost any other vegetation, the better the tree will grow. It is certainly beyond a doubt that, under such circumstances, the timber attains its greatest degree of soundness, strength, and general durability. There are, it is true, some belts and patches of Jarrah forest to be found upon many of the lower-lying portions of the district referred to, where the geological formation of those is composed of ironstone—as for instance in the country lying between Quindalup and Ksrridale—the timber is good in every respect; but where these lower-lying portions have fairly good sandy-loam soils the timber is sure to be more gummy and less durable than that on the higher ranges,

Some of this jarrah was sent some years ago to India and there was an unfavourable opinion formed of it: but of the hill-grown Jarrah we have received none but good accounts and I am sure it will suit Ceylon well. We have eight millions of acres of it and much of that is actually untouched yet."

THE FOOCHOW TEA IMPROVEMENT COMPANY, LIMITED.

(Extracts from Prospectus.)

Capital.—\$250,000, Hongkong Currency.

Dividend into 5,000 shares of \$50 each, of which it is proposed to issue at present the sum of \$125,000, in 2,500 shares of \$50 each, and the balance of \$125,000 in 2,500 shares, as may be hereafter determined on. Of the 2,500 shares now to be issued, 500 shares, which will be fully paid up, will be taken by the Vendors, in full payment of the properties, business, goodwill, machinery and effects purchased from them by the Company, and the remaining 2,000 shares are now offered to the public.

Directors.—Mr. Gustav Theodor Siemssen of Messrs. Siemssen and Krohn, Foochow, Merchants; Mr. Ernest Joseph Moss, of Messrs. Dodwell, Carrill & Co., Foochow, merchants; Mr. William Graham, of Messrs. Jardine, Matheson & Co., Foochow, merchants; Mr. Richard Henry Wallace Fraser, of Messrs. Fraser, Ramsay & Co., Foochow, merchants; Mr. Michael Gabriel Cisselef, of Messrs. Tokmakoff, Molotkoff & Co., Foochow, merchants; and Lui Yueh Yen and Huang Pai An, of Foochow, merchants. Secretary.—Mr. William Pitcairn Galton, Foochow.

The Company is being formed to acquire as a going concern the business of Tea Planters and Tea Merchants heretofore carried on by the Association called "The Foochow Tea Improvement Company," at Foochow and Pehling in the Fohkien Province of China.

Recent experiments in the manufacture of tea carried out by the Association at Pehling with the aid of machinery have been attended with much success, inasmuch as teas of greatly improved character and quality have been produced, and it is therefore considered that the time has now arrived when capital on a larger scale can be successfully employed in various parts of the Fohkien Province. In this connection, it should be stated that the Chinese Government officials have shown themselves favourably disposed towards the Company, and have expressed their intention to protect and assist it in every way.

The property to be acquired from the Association, in consideration of the allotment of the 500 fully paid up shares, comprises the goodwill of the business and all trade marks and chops used in connection therewith; the lands and premises in the Fohkien Province of China used for the purpose of the business, with a two-storied factory, 100 feet by 48 feet, and a house for the Chinese manager, an office, and coolie quarters; also machinery, consisting of a new "Venetian" firing machine, and three new rolling tables, the largest being a Jackson's 24 inch; also a sifting machine; the whole being worked by a water wheel, 12' in diameter and 2' broad, also the following machinery, namely:—1 Campbell's oil Engine, 10 horse-power; one Davidson's Sirocco, two Blackman's Fans and one Davidson's cutter; also 4,400 withering trays and stands, and scales and requisite godown appliances. The Company is also purchasing a cash balance at the credit of the Association, amounting to \$1,795.16. It is proposed that as the lands are situate in China they shall be vested in two Chinese shareholders as Trustees for the Company. This course is necessary, because doubts exist as to the legality of Foreigners holding land in China.

The Chinese growers in the vicinity of the Factory, who are extensive growers of tea, have always been willing sellers of green leaf, of which an ample supply is at all times available for manufacture at the same price as the price which they can obtain from their own

countrymen, and from the first they have always welcomed foreigners.

As regards the prospects of the financial success of the Company, the Directors would particularly draw attention to the advantage China now has over India and Ceylon in cheap silver, the exchange value of the rupee exceeding that of silver by fully twenty-five per cent.—This fully compensates for the taxation which China tea has at present to bear. The cheapness of land; the low scale of wages, and the excellent quality of Chinese labour are likewise facts which cannot be overlooked.

The machinery has been erected by, and is in charge of an English Engineer, who is the manager of the Company's property and resides at the Factory, and who has for some years been in charge of a tea factory in India. The Chinese manager resides at the Factory, and was recently sent to Ceylon by the Association, where he had practical experience in tea making on several large estates. It is proposed to take over the business as a going concern as from the 10th July 1897. The present intention is to enlarge the existing factory at Pehling, and to establish other factories in suitable districts.

COFFEE IN BRITISH CENTRAL AFRICA.

The following list will give an idea of the extent of the estates in Cholo:—

Mr. Adamson 200 acres of young and old coffee. Mr. McKinnon 200 acres, in bearing. Mr. Hunter 200 acres, 80 in bearing. Mr. Cox 250 acres, 80 in bearing. Mr. Whyte 200 acres, young coffee. Messrs. Buchanan 150 acres, in bearing. Mr. Noits 200 acres, 80 in bearing. Messrs. Pettitt 400 acres, 200 in bearing. Clamp & Stroud 100 acres young coffee, and 50 acres ready for planting. Mr. Taylor 140 acres young coffee and 60 ready for planting. Mr. Sinderham 250 acres, 60 in bearing. Mr. Kaesar 200 acres, 50 in bearing. Mr. Boyd 120 acres, 40 in bearing. Mr. Blair 100 acres young coffee. Messrs. Sharrer 150 acres young and old coffee. do. 200 acres ditto.

The following estates are on the Blantyre-Katung's road:—

Mr. Sharrer 120 acres of young coffee. Mr. McClaggan 120 acres in bearing. Messrs. Lamagna 700 acres in bearing. Mr. Hunter 100 acres, 20 in bearing. Mr. Sinderham 100 acres, 20 in bearing. Messrs. Pettitt 100 acres in bearing. Mr. Lloyd 50 acres of young coffee.

COFFEE IN ZOMBA DISTRICT, B.C. AFRICA.

Mr. R. Ross Stark has supplied us with the following information. Songani estate, which is situated about 6 miles north of Zomba, (the headquarters of the Administration), has a total extent of 1,787 acres. 250 acres of this have been cleared, and 200 are planted. 100 acres came into bearing this season, yielding a crop of 18 tons (or 3 cwt. per acre). Next year, as more land come into bearing, a crop of 25 to 30 tons is confidently expected. The plantation was opened some 4 years ago and a small crop of 3 tons was taken off a small acreage in bearing last year. The Zomba-Liwonde road passes within two or three minutes of the estate and this gives us direct communication with Blantyre and the lower river on the one hand, and Liwonde and the Lake on the other. The prospects of coffee in this district are excellent. At first the elevation of Songani, (about 2,500 feet), was considered by some to be rather low for successful coffee planting, but this has been proved to be a mistake. As shade is now becoming the rule in B.C.A., the lower elevation estates will benefit the most from it, and should give more remunerative crops, than those at the higher elevations of over 3,000 feet.

PLANTING NOTES.

THOUGH CEYLON has not been subjected to seismic disturbances I read that the planters there are erecting factories entirely of iron; this certainly is a step in the right direction and worthy of emulation on the part of Assam people, one or two of whom, I am concerned to hear, are about to reconstruct their buildings of masonry.—*Cor., The Planter.*

CACAO HUSKS AS CATTLE FOOD.—The *Indische Mercur*, of Oct. 30, says, that at the recent gathering of German chocolate manufacturers held in Hamburg it was stated *inter alia* that experiments in the use of cacao husks as cattle food had yielded favourable results. This is good news for cacao planters, and ought to cause a rise in the price of the beans!

COFFEE CULTIVATION AT THE GOLD COAST.—During the last two years the Government has introduced machinery for pulping and curing coffee, and consignments of both coffee and cacao from the Gold Coast have been forwarded through the Crown Agents for sale in the London market. This plan afforded the best means for testing the commercial value of the produce, and the result shows that coffee and cacao can be grown in West Africa capable of realising good prices in European markets. Much, however, still remains to be done to induce the natives to cultivate and cure their produce in a satisfactory manner.—*H. and C. Mail*, Nov. 5.

WEST AUSTRALIAN JARRAH.—We call attention to the interview on this subject on the preceding page. We visited the chief Jarrah Forest of Western Australia in 1895, and have ever since watched the development of the use of the timber. Mr. Traylen has left a copy of a valuable work with us:—

Report on the Forests of Western Australia, their Description, Utilization, and Proposed Future Management, with Plan and Illustrations, by J. Edmie-Brown, F.L.S., F.R.H.S., Conservator of Forests for Western Australia, Late Conservator of Forests for South Australia and Director-General of Forests in New South Wales).

ARE BANANAS BENEFICIAL?—In an exchange we read that a boom in bananas, baked bananas, has been started in the United States, the well-known fruit being now said to be an "ideal food" for the nervous, the anæmic, and for brain-workers. Strange to say, the raw fruit is said to be dangerous, as it contains "germs"; but when baked it acquires properties never heard of before. In this country we cannot get bananas in perfection; but they have them in fine condition in New York, to which city and other places on the Atlantic seaboard they are quickly transported from the Bahamas. Fruits of *Musa paradisiaca* and *M. sapientum*, the banana and the plantain, have long been known as a staple article of food in tropical countries, where they are cultivated just as the cereals and the farinaceous tubers are in temperate regions. In fact, cultivation has produced considerable variety in form, colour, and flavour. Humboldt and Bous-singault estimated that in a suitable climate, and well cultivated, a banana plant will produce on an average three bunches of fruit weighing 44 lb. each per annum, and that in hot climates more than 130,000 lb. of good food could be grown per acre—an amount greatly in excess of the yield of potatoes, which are, moreover, said to be less nutritious. That has, however, been disputed; but all travellers and investigators aver that the banana is an excellent food baked, roasted, fried, or boiled. In this country bunches weighing as much as 80 lb. have been grown in hot-houses.

COFFEE-GROWING IN NEW SOUTH WALES.

The following note has been submitted by Mr. C. Skelton, who recently visited the northern districts to report on the prospects of coffee-growing:—

Since my article on coffee-growing appeared in the *Agricultural Gazette* for January last, I have, at the instance of the Minister for Mines and Agriculture, inspected the Clarence, Richmond, and Tweed Rivers districts, with a view to ascertaining their capabilities for the production of coffee. In all three districts I saw large tracts of land, cleared and uncleared, well suited for the purpose; soil and climate are all that could be wished for, as also are the specimens of coffee trees I saw growing in the different districts, strong healthy, well-grown trees; in many instances, at the time of my visit, laden with crops. With the wonderful fertility of the soil and the general suitability of those parts of the Colony for the purpose, it is surprising that the industry has not progressed beyond the experimental stage; for, with the exception of a small plantation of 800 or 900 trees made by Mr. Bale, at Chatsworth Island on the Clarence River, and groups of two or three trees in gardens in the different districts, coffee, to any appreciable extent, has not been tried.***

In the northern rivers districts, I learned the usual rates for felling are from £1 to £1 2s 6d per acre; lopping will probably cost 10s an acre more, but it will be found after the fire to be 10s well expended, as it will, to a very great extent, do away with the usual piling and clearing up after the fire. To attain the same end, always set fire to the lee side of the clearing, and let it burn up against the wind; it will burn more slowly, but more effectively.**

The conditions for planting here being somewhat different from India and Ceylon, where cheap coolie labour is obtainable, I believe it would be an advantage to set out the coffee trees wilder apart than 6 feet, as formerly stated; say, 7 feet by 7 feet, or even a foot more; this would admit of the use of a one-horse light scarifier between them to keep the ground clear of weeds; it must be a very light scarifier, as the roots of the coffee are very near the surface. This space would also allow of the passage of some sort of vehicle to pick up the bags of cherry coffee in crop-picking time for transport to the curing works.***

Where the plantation is a considerable one, and pulping machinery, fermenting and washing cisterns, &c., have to be employed in the curing of the crop, it is scarcely possible to give directions that could be successfully carried out by a novice. When it is taken into consideration that in Ceylon, no man was deemed fit to take charge of a plantation until he had served for at least three years under an experienced planter, it will be understood there is a good deal to learn, and the proper conduct of curing operations is by no means the least part of it. The variations in the prices of coffee in the European markets—as much as 80 per cent and even more—are almost wholly due to the manner in which the curing of the different parcels has been carried out. It was principally for this reason, that in my report to the Minister, I suggested the opening of two demonstrative plantations by the Department of Agriculture, as object lessons to intending planters in the districts referred to. I can see no other way, with any hope of success, of imparting the requisite information.—*Agricultural Gazette*, for Oct.

COCA CULTIVATION IN BRITISH INDIA.—After consideration, the Government of Madras has decided not to engage actively in the manufacture of cocaine, but to do all in its power to foster the cultivation of coca in British India. The Curator of the Government Gardens, Nilgiris, has therefore been requested to obtain a small supply of seeds every year and to offer for sale the plants reared therefrom.—*Chemist and Druggist*, Nov. 6.

DRYING PEACHES FOR HOME USE.

MR WILLIAM ANDERSON, of East Kempsey, sends the following note on drying peaches for home use:—"Peel the peach. Cut it into about five pieces, cutting from the outside into the stone. Take a strong needle and a piece of cotton a yard and a half long (No. 16 sewing cotton will do), make a small slip-knot at the end of the cotton and thread the peaches on, putting the needle from the outside of the peach to the inside. Hang up the strings of fruit in a verandah, or where the wind and sun will get at them (I do not take mine in at night unless the weather is wet). Two or three days will dry the fruit, when it should be removed from the cotton, and placed, a few at a time, in the oven, being allowed to remain there till very hot, but not scorched or burned. Pack away in tins or some airtight vessel till required for use."—*Agricultural Gazette*, for Oct.

NATAL TEA INDUSTRY.

It is satisfactory to learn that, notwithstanding the much-talked-of trade depression, the Natal tea industry appears to be making steady progress. The fact that Messrs. J. L. Hulett & Sons, Limited, have found it necessary to erect new premises, warehouses, offices, &c., in Durban, is an indication of the gradual advance of this industry. The total output of the season just commenced is expected to amount to 1,000,000 lb., of which the firm under notice will probably produce about two-thirds. The trade secured with the Cape Colony and the Transvaal is gradually increasing, and when the free interchange of Colonial products is agreed to between the States and Colonies of South Africa, Natal tea growers and manufacturers hope to find a much larger and more appreciative market. It is noteworthy that Messrs. Hulett & Sons have recently established offices in London, and are doing their utmost to push Natal teas in the Old Country. The opinion recently pronounced by a tea expert at Johannesburg that Natal teas are now so well manufactured that they are equal in appearance to those of Ceylon and India, augurs well for the success of the efforts being made to obtain a footing in the Home market, and it will be interesting to watch the result of the experiment.—*Natal Mercury*, Oct. 29.

COMMERCIAL OIL OF CITRONELLA.

Citronella oil, which is now extensively used in perfumery and for other purposes, is chiefly obtained from Ceylon and Singapore. It has been noticed for some time that the native-distilled oils have an aroma much inferior to those distilled by two English firms, viz.: Messrs. Fisher, of Singapore, and Messrs. Winter and Son, of Galle (Ceylon), and that these two classes of oils also show very marked differences in physical characters, as the following average figures indicate:—

The oils of the first class, i.e., native-distilled, have a high specific gravity, .910 at 15° C. an optical rotation of -14° in a tube of 100 m.m., and yield a slight deposit upon treatment with five volumes of 80 per cent. alcohol.

The oils of the second class have a specific gravity of .886 to .889 at 15° C., a rotation of from -4° to -6° in a tube 100 m.m., and are readily soluble in 80 per cent. alcohol.

No details are known of the method of distillation adopted in the two cases, but it is stated that there is no difference in the variety of grass from which the oil is obtained. It has been suggested that the observed differences are due to the sophistication of the oils of the first class, but the nature of the adulterant, if any, has never been determined, and this view of the matter has been questioned.

To clear up the existing uncertainty, Messrs. J. C. Umney and Swinton have examined a number of commercial samples of both classes of oil, and their results were communicated to the recent British Pharmaceutical Conference. The following are the most

important of these:—On submitting the oils to steam-distillation considerable differences were observed. In the case of oils of the second class practically the whole readily passed over, whereas those of the first class gave a residue amounting to about 37 per cent. of the total quantity. This behaviour would suggest that the oils of the English firms are steam-distilled, while those prepared by the natives are obtained by fire heat. The residue, after purification, distilled between 245° and 280° C. at ordinary pressure, and had a high specific gravity. It is stated to possess all the characters of a sesquiterpene, but differs in physical properties from any previously-described bodies of that class. It is odourless and therefore a valueless constituent of the oil, and as it is only fairly soluble in alcohol, it affects the solubility in that liquid. Its high specific gravity accounts for the differences shown by the two classes in this respect, but as it is optically inactive its presence does not explain the higher optical activity of the native-distilled oil. To determine the cause of this, the first fractions of the oils were examined, in order to ascertain the nature of the terpenes present. After refractionation the first 6 per cent. of each was collected. In the case of the native-distilled oils this boiled below 170° C., and had a rotation of -42° in a tube of 100 m.m., its specific gravity was .859 at 15° C. These characters do not correspond with camphene, the only optically active terpene hitherto found in citronella oil, and, by acetylation and subsequent saponification, camphene was proved to be almost entirely absent. The corresponding fraction of the oil of the second class had a rotation of only -11° in a tube of 100 m.m., and its boiling point rose to 190° C. It was proved to consist chiefly of camphene, the active terpene of the former class being absent. There can be no doubt, therefore, that the high optical activity of the native-distilled oils is due to the presence of this terpene, which does not exist in, or has been removed from, the oils of the second class. The authors conclude from this that the native-distilled oil is in no way sophisticated, but is a genuine natural oil. Its high specific gravity and rotatory power are due to the presence of the above-mentioned sesquiterpene and terpene, which also affect the solubility in alcohol, and, by acting as diluents, impair the odour value.—*Imperial Institute Journal*.

BRAZIL COFFEE NOTES.

A telegram of the 17th inst. from Ceará says that the Baturité coffee crop is expected to be large.

Dr. André Werneck says that at the present cost of growing coffee the price of 12\$ an arroba does not pay expenses. He accordingly suggests that whenever the price falls below that rate coffee shall be exempt from export duty, which should moreover, he thinks, be regulated by a sliding scale when prices are higher.—*Rio News*, Oct. 19.

CEYLON AND INDIAN TEAS.

An old Ceylon friend in London writes again to hint at improvement in the 'make' of Ceylon teas:—

"So far as I can understand from the brokers the Ceylon samples I last sent you were high grown teas, but what I wished to impress upon the planters was the *make* of the teas and it did not matter one fig whether they were high or low. Any one would observe the superior finish of the Indian teas and it a very exceptional thing to see Indians manufactured like the undesirable teas I sent. I must say I think Ceylon people are not inclined to take suggestions that would result to their own benefit. Teas of the kind I refer to must be classed with low classed teas as they are not suitable for blending with teas well made and an improvement of 1d. a lb. would well repay a little extra care. Of course the present position of the market blinds then to

the fact that the present price will not long continue and it is only attention to manufacture that will keep up their average to a paying point."

THE CACAO CANKER—II.

Shortly after the publication of the last Circular in this Series, the reports on specimens sent to Kew were received through the Colonial Office. These, with the covering letters, are given below, with such footnotes as are needed to make them more readily intelligible. * * *

[Mr. Chamberlain's letter is simply a formal covering letter in which he states no specialist will be sent out, in view of what Mr. Thiselton-Dyer writes:—

"I enclose a report upon these specimens, which I think leaves little room for doubt that the disease is due to a fungus, the growth of which has been promoted by unsuitable methods of cultivation. I further enclose a memorandum by the Assistant Director as to the remedial measures which the circumstances suggest. With this information before him the Director of the Royal Botanic Gardens, Peradeniya, ought to be able to deal with the problem. I am not therefore prepared to recommend that a specialist should be sent to Ceylon as suggested by the Governor."—Ed. T.A.J.]

Memorandum from the Assistant Director Royal Gardens Kew, to the Director.

The probability is that the canker in cacao trees in Ceylon is caused by a fungus, the nature of which is at present imperfectly known.

2. It is understood that since the attack of the *Helopeltis Antonii* some change has taken place in the method of cultivating cacao in Ceylon. More shade is used than formerly, and the trees are covered in to such an extent that the ground underneath is constantly kept moist and covered with a heavy layer of damp dead leaves. There is no definite information in regard to the amount of drainage provided. This is a vital point. In all damp situations and those liable at any time to the lodgment of water during heavy rains there should be drains cut two feet or more deep between every row of trees. In fact, the bottom of the drain should be below the level of the feeding roots of the tree.

3. In Trinidad and Grenada draining cacao has lately received considerable attention. Where the soil is "sour" through accumulated moisture the trees have died over considerable areas. The only cure for this is deep draining, turning over of the soil, and the application of a small quantity of lime or other suitable ingredient.

4. Everywhere young cacao appears to require some shade, but the extent to which mature trees require shade depends very much on the locality. In Trinidad the trees are usually shaded all over the island. In Grenada, on the other hand, the trees have little or no overhanging shade, but are usually protected by shelter belts planted or allowed to grow on the ridge.

5. The Ceylon cacao planters would do well (1) to examine the drainage of their estates very carefully; (2) to break up the soil where the trees have died and treat it with lime to kill the mycelium* in it; (3) to isolate the healthy trees from the unhealthy by deep trenches, and give only the amount of shade absolutely necessary.—D. MORRIS.

Report by Mr. G. Massee, Principal Assistant (Cryptogams) in the Herbarium, Royal Gardens, Kew.

The material sent for examination is insufficient for the determination of the fungus, but the exact agreement in structure, &c., of the mycelium* pre-

* The body of a fungus, made up of fine colourless threads, as may be readily seen on examination of a piece of mildew or mould with a good lens.

sent in the different pieces of bark suggest a fungus as the cause of the disease, and furthermore, that the fungus belongs to the group causing root disease. If the roots of a diseased tree are removed and portions kept moist under a bell-jar, the characteristic snow-white nodulose mycelium would in all probability cover the roots in a few days.

The sporophores* of such fungi are only produced on dead and thoroughly decayed host plants.

The two conditions favouring the spread of root disease are: (1) accumulation of humus,† &c., on the ground, which retains moisture and favours the spread of the mycelium from tree to tree; (2) overhead shade.

Diseased trees should be isolated by narrow trenches, 8 to 10 inches deep. These retard the spread of the mycelium. The removal of the roots of dead trees and sterilization‡ of the soil (by fire, &c.) is most important.

Ascertain if the disease attacks native trees, may be in a modified form.—G. MASSEE.

It will be seen from the above that the home authorities regard the fungus as one of the class of root-disease fungi. Without the reproductive organs, the exact identification of a fungus is all but impossible, and until quite lately no sign of such organs has been discovered on any of the diseased cacao.

It is obvious that if the canker on the stem be merely an indication of diseased roots, the treatment recommended in the preceding Circular will have to be modified: mere removal of diseased parts of the stem will be evidently only a temporary measure.

Most observations made in Ceylon seem to contradict the supposition of its being a root disease, and the publication of this Circular has therefore been delayed for further investigation of the subject. It so happens that the group of fungi causing many of the bark cankers of trees is very closely allied to the group causing root diseases.

These bark canker fungi as a rule can only enter the stem by way of wounded surfaces on the bark, but a very slight wound is often sufficient. The frequent connection of the cacao canker with wounded places has been pointed out in the preceding Circular.

Reproductive organs which appear to belong to the fungus causing the cacao canker have recently been discovered on the bark of the stem, and indicate that the fungus does belong to one of the two groups just mentioned. As no sign of these organs can be found on the roots, and the mycelium mentioned in Mr. Massee's report has not been seen on roots treated in the way there described, it seems more probable that the canker is only a bark and not a root disease. Again however the final decision of this question requires experiments in the infection of healthy trees, &c., which are now being carried on at Peradeniya, and also further reference to the authorities at home, it has been decided to publish this Circular without further delay.

The presence of the disease, as stated in the preceding Circular, is largely connected with insufficient drainage, and Dr. Morris's recommendations on this subject deserve careful attention. In many cacao plantations in Ceylon the soil has become sour through insufficient drainage, and the application of lime in some of these cases has been most beneficial.

Besides its action in removing the sourness of the soil, the application of lime helps to kill the fungi that may be present, and is therefore much to be recommended.

* The spore-bearing organs of the fungus: the spores are the detached portions which reproduce the fungus; placed under suitable conditions a spore germinates and gives rise to a new mycelium.

† Decaying organic matter, whether of animal or vegetable origin.

‡ The killing of all living matter: spores, mycelium, &c.

Dr. Morris's remarks on shading should also be noted. Mature cacao can do with very little shade from the sun, but requires protection from wind. In the Botanic Garden at Anurādhapura the *Forastero* cacao does excellently with practically no overhead shade at all, hot and dry though the climate is. The shade in most Ceylon plantations was provided to avoid the attacks of *Helopeltis*, and now that the trees have grown very large it is probably denser than is necessary for that purpose. The reduction, if made, should be very gradual, otherwise the sudden increase of the crop will tend to weaken the trees. This reduction would act upon the fungus causing the canker in two ways: by drying the soil and thus helping to prevent its getting sour and so weakening the trees, and by the direct action of the sunlight, which checks the growth of fungi and is often fatal to fungus spores upon which it acts. Care should be taken to see that cacao is well sheltered from wind: not merely is wind harmful to the plant itself, but it also carries the spores of disease from one plant to another.

The period at which further spread of the disease usually takes place is now approaching, viz., the wet weather of the north-east monsoon, and especial care should be taken to destroy as far as possible all diseased trees, and parts of trees, to prevent the disease extending. The reproductive organs both of root and bark diseases are produced only on dead and decaying parts of diseased trees, and if these reproductive organs can be destroyed, or prevented from forming, as the case may be, the disease will thus be prevented from spreading to fresh trees.

To this end it is essential that the destruction be by fire, which alone is certain to kill the fungi. Also, the destruction should be on the spot where the diseased tree grew. If infected trees or parts of trees are carried about the estate, they will spread the disease as they go by scattering the fungus spores. For the same reason coolies should be prevented from going amongst healthy trees immediately after working amongst diseased ones. They should wash themselves before doing so. It would be advisable to employ a separate gang of coolies in working with diseased trees.

All diseased trees should be cut down to the ground, or better rooted up, and burnt upon the spot, and at the same time all the dead leaves and other rubbish lying round about them should be burnt. The surface soil should be turned over and treated with lime and the ground left fallow for some time. If planted again in cacao, *Forastero* varieties should be employed (see remarks on pages 10 and 11 of the preceding Circular).

On estates where the disease is widespread it would be well to burn all the dead leaves and lime the soil, as there will probably be fungus spores lying on the ground ready for germination in all parts of the estate.

In dealing with diseases caused by parasitic fungi, the aim is prevention rather than cure. Once a tree is fairly attacked cure is usually impossible, and it is best to kill and destroy it.

In the neighbourhood of diseased trees not merely the soil, but also the surrounding healthy trees (including of course the shade trees) will be more or less covered with spores of the disease. Those on the soil may be killed by the lime treatment above described, but considerable danger remains from those on the trees, which under favourable conditions will germinate there and produce further attacks of the disease. These spores may be killed by the application of various fungicides. The best

DEAFNESS. An essay describing a really genuine Cure for Deafness. Ringing in Ears, &c., no matter how severe or long standing, will be sent post free.—Artificial Ear-drums and similar appliances entirely superseded. Address THOMAS KEMPE, VICTORIA CHAMBERS, 19, SOUTHAMPTON BUILDINGS, HOLBORN, LONDON.

general fungicide is Bordeaux mixture. In Europe this can be applied to leaves as well as stems, but as it is said to cause damage to the former in wet seasons, it would be well in Ceylon to apply it only to the stem. This, however, is of less moment, as the disease does not appear to attack leaves or young shoots, and if all the leaves that fall from the plants are raked up and burnt the danger from the spores that may be resting on them will be lessened.

The composition of Bordeaux mixture is:—

Copper sulphate (blue vitriol) ..	6lb.
Quicklime	4lb.
Water	45 gallons.

The vitriol should be dissolved in a little water and boiled; to it should be added, while hot, the lime which has been slaked in a small quantity of water and stirred into a paste. The two should be thoroughly mixed and the mixture diluted to 45 gallons. It should be tested by holding a clean steel knife in it for two or three minutes. If a raddish stain of copper is formed on the knife there is not enough lime present, and more must be stirred in until the mixture is neutral and no longer produces any stain. Before use, and while in use, it must be kept thoroughly stirred, as the important part of it is the sediment rather than the fluid. The mixture may be applied with a brush or a spraying apparatus. The latter, if used, must be thoroughly cleaned with hot water immediately afterwards, or the tubes and taps will be clogged.

Another useful fungicide is the lime and sulphur wash, but it must not be applied to the leaves. Its composition is:—

Unslaked lime ..	25 to 40 lb.
Salt ..	15 lb.
Sulphur ..	20 lb.
Water ..	60 gallons

To mix, take ten pounds of lime, twenty of sulphur, and twenty gallons of water, boil till the sulphur is thoroughly dissolved; take the remainder of the lime and fifteen pounds of salt, slake, mix with the first lot, and add enough water to make up to sixty gallons. Strain and use when milk-warm.

Either of these mixtures will kill the spores on the bark, but if the disease is already established on the tree it is useless to apply them, and the tree should be killed.

Of course the stems of the shade trees should be treated with the mixture as well as those of the cacao itself.

Heavy rains will soon wash off most of the fungicide, and a new coating should be given every month or so.

If care is taken to destroy all dying and dead stems, leaves, &c., on which the fungus might develop its reproductive organs, and if fungicides are applied regularly for at least six months, there would seem to be a fair chance of eradicating the disease to a large extent. The completely exterminate it may be regarded as all but impossible. All that can be done in cases like this is at best to reduce the prevalence of disease to a large extent by killing and burning diseased trees, applying the preventive measures to the survivors, disinfecting the soil as far as possible, and taking more care in cultivation to keep the trees in good health, and thus render them less liable to disease.

The chief causes of ill-health among cacao trees have already been mentioned in the preceding Circular, and attention may again be drawn to the recommendations there made, especially those relating to the treatment of wounds and the planting of *Forastero* varieties.

There is a good deal to be said in favour of the method employed by some planters of allowing the suckers to grow. Unskilful removal of them affords openings for disease to attack the trees. Probably on estates where there is much disease it would be better to leave them on the trees.

JOHN C. WILLIS,
Director, Royal Botanic Gardens,

THE CACAO DISEASE.

The Director of the Botanical Gardens continues his good work and the receipt of Reports from Kew Gardens enables Mr. Willis (in his circular No. III) to discuss at some length and in a way marked by practical good sense, the pest affecting so many of the Ceylon cacao fields especially in the Wattegama and Matale Districts. It is clear as the outcome of the discussion which is reproduced above—that there is no royal road to a cure—no heroic remedy;—but planters will find some good advice and suggestions which are well worth trying. More can be done by the planters themselves by intelligent experiments in the fields affected, than in any other way, and if results are carefully reported, the whole community concerned, cannot fail to be benefited. We need do no more now than direct special attention to what is written on the subject by Messrs. Morris and Willis given above.

MINOR PRODUCTS :—DRUG REPORT.

(From the *Chemist and Druggist*.)

London, Nov. 11th.

CARDAMOMS.—A fairly large supply (211 packages) was offered today, of which about 130 found buyers at barely steady prices, and in some cases a slight reduction in value. Ceylon-Mysore, fair long round medium palish, realised, 3s 9d to 3s 10d; fair medium brownish 3s 6d; small palish 3s 4d; very small ditto 3s 1d; medium brownish split and dull 2s 6d to 2s 8d per lb. Tellicherry cardamoms were all bought in. Fair to good bright Seeds sold at 3s 7d to 3s 8d per lb.; dull ditto 2s 6d; really fine seeds are help 4s per lb.

COCOA-LEAVES.—The cocoa-leaves offered on our market nowadays are of much poorer appearance than those which we were accustomed to see a few years ago. At today's sales 86 bales were shown. They consisted mostly of ordinary partly broken greyish Truxillo leaves, which are held at about 6d per lb., and of Huanoco leaves of dark colour, which were bought in at 8d per lb.

CROTON SEED.—The only parcel of East Indian croton seed offered at auction was one of four bags very dark mixed seed from Colombo. This was bought in at 50s per cwt. nominally. Another parcel of 10 bags dark grey small seed from Shanghai, which has been offered before, was also bought in at 50s per cwt.

KOLA-NUTS.—Steady. At auction today a fairly large quantity was offered. Good washed African are held at 6d to 7d per lb., dark to fair at 4d per lb. No sales were made.

OILS (Essenti l).—Citronella oil is quieter at 1s 4½d per lb. nominally on the spot. To arrive 1s 2½d per lb., c.i.f. is asked for drums, although recently as much as 1s 4½d per lb., c.i.f. was paid. Lemongrass oil still rising. Cajuput oil still remains very scarce and dear. At auction 2 cases of 60 bottles each were offered. They were imported as far back as 1880, and sold at the high figure of 1s 1d per bottle, showing a decided advance in price. Two cases white Jamaica Oil of bay (each 28 quart bottles) were bought in at 7s per lb. Cinnamon oil of fine quality is scarce. Two cases fair (T Perera) oil were brought in at 1s 6d per oz., and 2 cases "sweet" oil at 5s per oz. Eucalyptus oil was plentifully represented at today's public sales. The chief consuming season is now at hand, but nevertheless the market shows no life. Nine cases pale yellow oil of good aroma from Melbourne were bought in at 1s 2d per lb., four cases pale "Cygnet" oil at 1s 7d per lb., eight cases fair "K.M.C." Tasmanian oil at 1s 8d per lb., and ten cases (two 35-lb. tins) fine globulus oil from Lisbon at 1s 9d per lb. For ten cases fair quality oil from Adelaide 1s 1d per lb. was suggested as the price. Twenty-five cases "Lubra" brand were bought in at 2s per lb., and for ten cases nondescript of fair appearance a bid of 9½d per lb. was refused. Distilled W.I. Lime oil is still plentiful. At today's auctions four cases of good quality from Jamaica and Dominica were shown, and sold at 3s 4d per lb., which shows an advance of 1d on the recent figure. There were also two cases of expressed lime oil, of nice appearance, each containing twelve 16½-oz. bottles. One realized 4s 3d per lb., a considerable reduction on the last price.

VANILLA.—862 packages of mostly new crop Bourbon and Mauritius will be offered at auction tomorrow (Friday) when lower prices are expected.

COLOMBO PRICE CURRENT.

(Furnished by the Chamber of Commerce.)

Colombo, Dec. 7th, 1897.

THE
AGRICULTURAL MAGAZINE,
COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for December :—

Vol. IX.]

DECEMBER, 1897.

[Nos. 6 & 7.

SAESON REPORTS.

ESTERN Province.—Paddy. Yala harvest over; Maha cultivation begun, and some damage caused by rain, but a fairly good crop is expected.

Central Province.—Paddy. Yala harvest nearly over, prospects of yield good; Maha sowing and transplanting going on. Rainfall in Matale 7·67 in. Health of cattle good.

Northern Province.—Paddy. Sowing practically over, and most of the plants are up. More rain wanted. Rainfall in Jaffna 1·88 in. Health of cattle satisfactory.

Southern Province.—Paddy. Maha crop sown, weather favourable on the Galle side, but rain wanted in the Hambantota district. Rainfall in Galle 1·76 in.

Eastern Province.—Paddy. Late pinnari being harvested and in some places threshed; Munmari cultivation for 1898 progressing. Rainfall in Batticaloa 1·14 in., in Trincomalee 2·81 in. Cattle murrain still in the Batticaloa district.

North-Western Province.—Paddy. Maha crops progressing, and prospects fairly good. Cattle murrain reported to be on the increase since September in the Kurunegala district. Rainfall at Puttalam 1·64 in.

North-Central Province.—Paddy. Yala crops reaped, cultivation began for Maha in some places. Murrain prevailing in some villages in Eppawala and Kalagama Korales.

Province of Uva.—Paddy. Preparations for Yala going on, and in some parts sowing commenced. Fruits and vegetables plentiful and cheap.

Province of Sabaragamuwa.—Paddy. Yala harvested, reaped and stored; the yield on the Ratnapura side not good. Maha prospects good in Kegalle district, but unfavourable in Ratnapura. Health of cattle good, saving some cases of foot-and-mouth disease.

OCCASIONAL NOTES.

Erratum.—In the November number, on page, 41, the mean rainfall for October at the School of Agriculture should be 139 and not 19 in.

Early in November the students of the School of Agriculture and Training School were taken by the Superintendent over Messrs. Vavasseur's Coconut mills by arrangement with the Manager and saw the various operations in connection with the desiccation of coconuts and the preparation of coir fibre. Our thanks are due to Messrs. Vavasseur & Co. for permitting the students to go over their works.

Mr. E. Roosmalecocq, Instructor in Surveying and Levelling at the Technical College, has been appointed teacher in surveying to the students of the Forestry School, and has already taken up duties.

In his address on the opening of the new session of the Legislative Council on November 5th, His Excellency the Governor made the following statement:—"An endeavour is being made to bring the Gardens into closer touch

with the public by the publication of periodical circulars on important subjects. Mr. Willis (the Director of Botanic Gardens) intends to arrange for personal instruction by members of the Staff, whether by lectures away from Peradeniya, or by demonstrations in the Garden and elsewhere. The latter branch of work, however he thinks should be connected with the School of Agriculture, and he proposes to bring it before the Committee dealing with that institution."

Arrangements have been made for the appointment of a "Scientific assistant" to the Director of Botanic Gardens. For the first occupant of the post the Director is trying to get a man with sufficient training in the study of fungi to enable him to work out the life histories of the fungi of the cocoa and betel diseases and others. Another man might be afterwards obtained who would study rubber thoroughly, then perhaps a skilled viticulturist to teach vine-growing in Ceylon, and so on.

Tous-les-mois, St. Vincent arrowroot and Queensland arrowroot are different names for *Canna edulis*. The farina from the tubers of this plant, which has been more than once referred to in the Magazine, [vide vol. VI., No. 3, page 28, and vol. IX., No. 4, page 35] is considered to be equal to or more valuable than ordinary arrowroot, though not so white. In 1894 a crop of *Canna edulis* was raised on the School of Agriculture grounds. We may mention that the preparation of arrowroot from this plant is not unknown to the natives. In Badulla and the Rayigam Korale it is cultivated for this purpose.

We read in the Government Resolution on the report of the Agricultural Department of Bengal for 1896 the following reference to *Agricultural Education*:—"The Agricultural Conference held in Calcutta in 1896 recommended (1), that the course of study in primary and middle schools should be revised so as to include a graduated series of lessons in agriculture and in other subjects of elementary science; (2), that agricultural classes should be opened in connection with the Seebpore Engineering College; and (3), that a certain number of appointments in the public service should be reserved for those who have received an agricultural education. The sanction of the Government of India has recently been received for the opening of agricultural classes at Seebpore, and the details of the scheme, which will soon be published, for giving effect to these recommendations of the Conference, are now being worked out. We also note in the same connection that agricultural exhibitions were held in no less than 15 centres during the year, and that they were all assisted by Government with grants of money which were chiefly spent in prizes. The expenditure of the Department on *agricultural enquiry and improvement* alone (excluding pay of superior establishment, silk experiments, veterinary work, &c.) was Rs.10,354; and the Lieutenant-Governor expresses his opinion that the expenditure which is spoken of as *small* is more than justified by the information collected and practical results achieved.

We would draw special attention to the recommendations referred to above, especially to that by which a certain number of appointments will be reserved for those who have received an agricultural education. It is to be hoped that the Ceylon Government will also come to recognise the necessity of holding out some inducements in order to draw to the School of Agriculture each year a number of students of fair intelligence and respectability, so that the teachings of modern agriculture might find in them a good nidus, and eventually leaven the whole mass of our rural population.

Among the visitors at the School of Agriculture during November was Professor J. L. Janson, Professor of Agriculture in the Imperial University of Japan, Tokiyo. Prof. Janson spent a couple of hours on the premises, in going over the grounds, and visiting the Government dairy in which he was particularly interested. It would appear that while the work of the Japanese Agricultural College has developed in the direction of agricultural chemistry, little or nothing is being done in the way of dairying and cattle breeding. Altogether the Professor's visit was a most interesting one, and having done a great deal of travelling, his agricultural experience is both extensive and valuable.

The Colonial Veterinary Surgeon left for the Kurunegala district during the latter part of November, as cattle plague was reported to be prevailing there. Mr. Sturgess, who made some serum inoculation experiments on the last occasion he visited an infected district, intends to carry out further experiments, this time with bile, on the lines recommended by Dr. Koch.

By the time the present number of the *Agricultural Magazine* reaches the hands of our readers, the Christmas season will have begun, and we therefore take the opportunity afforded us here of wishing each and every one of our supporters and well-wishers a bright and happy Christmas and the prospect and a prosperous New Year.

As usual, the present issue of the Magazine appears as a double number at this season. Subscribers will please therefore note that Nos. 6 and 7 appear in a combined form.

We would draw attention to the advertisement on the cover referring to bee hives.

Tagasaste or Tree Lucerne (*Cystisus proliferus*) which has been so much written about as a fodder plant would not seem to have much chance of extended cultivation in the Island. Mr. Nock, of the Hakgala Gardens, writing about the tree says: "The *Cystisuses* generally do not do well here, being very uneven in growth,"—one year making long shoots and the next scarcely any at all, and then going right out during the heavy rains or drought. However, *Cystisus canariensis* has done fairly well for some years, and last year we raised a few plants of the Tree Lucerne (*C. proliferus*). They did well for a time, and then most of them

suddenly died. We have now one plant over 3 feet high which is perfectly healthy, and the foliage looks soft and tempting as a fodder. I am afraid it would never thrive in the lowcountry." The Superintendent of Government Botanical Gardens, Saharanpur, writing to us says: "I have several times tried Tagasaste. It succeeded very well during the cold season, but always died off in the rains. I should say it has no chance with you on the plains, but it might thrive at one of your hill stations."

What is known as "Jarrah timber" is got from *Eucalyptus marginata*. We note that *Timber*, of May 20th, 1893, published a letter from Cathcart W. Methuen, Engineer-in-Chief of the Natal Harbour Board, in which he describes experiments made with Madagascar timber as compared with Australian Jarrah wood, and states that the Madagascar timbers were practically untouched while Jarrah was much worm-eaten.

Recorded by A. R. JEREMIAH.

THE VALUE OF PLANT ROOTS AS TILLERS OF THE SOIL.

This is the title of a communication to the last number of the Royal Agricultural Society's Journal, made by a writer (Robert H. Elliot) who states that he began life as an agriculturist in Mysore, and has since then been farming in Scotland. The object of the communication is stated at the outset to be to show how, in the face of foreign competition, farmers could produce more cheaper than now, and at the same time largely improve the fertility of their soils. But we will let the writer speak in his own words.

To clearly apprehend how both these objects can be carried out, it is necessary in the first instance to remark on the causes of the decline of fertility in most soils. And, first of all, let

us examine the conditions when the soil is taken in from forest lands, or from the original turf which has never been disturbed from time immemorial. If, then, we clear down the former, as I often have, we find that, partly from the land not having been exposed to the elements, but mainly from its being interpenetrated with the rootlets of jungle, shrubs, and tares, the soil is in the most perfect physical condition. But as time advances the rootlets of course decay, and the soil then loses its original condition and becomes a bad nidus for the plant; and so much so, that while in newly-opened land the young coffee plants flourish exceedingly, in the land that has been long ago opened the plants cannot be successfully grown without much cattle manure, or with the aid of virgin topsoil taken from the adjacent forest land. And many years ago we had excellent proof that the failure of the young plants was not owing to the decline of the, strictly speaking, chemical condition of the soil; for on comparing an analysis of the original soil with an analysis of soil from which sixteen crops of coffee had been taken without manure, we found that the soil was little the worse, and only showed a slight deficiency in lime, the leaves which annually fall from the large trees which shade the coffee having evidently supplied the exhaustion caused by the crops. The examination was carefully conducted by the late Professor Anderson, of Glasgow, and a brother-planter who called on him to hear the result very naturally asked how it was that, if the soil was only so slightly impaired, we could hardly grow young coffee plants in it, or but very unsuccessfully. "Simply," replied the Professor, "when turf land is first ploughed up, it being deeply interpenetrated with grass roots, is in the same condition as a new forest soil, and no fertility is apparent till after the lapse of a greater or less number of years. Then as the vegetable matter becomes exhausted the soil solidifies and becomes not only tough but shallow, as it is no longer thickened and disintegrated by roots, a decline in fertility being the result; and though tillage may lessen the evil for a time, the particles of soil, being no longer kept apart by vegetable matter, soon run together, and thus the land becomes a bad nidus for the plant. There are of course exceptions to every rule, and I may mention one of them, which after all proves the vast importance of a fine physical condition of the soil. . . . A small quantity of manure on land in good physical condition, such as a fine sandy loam, goes much further than in another of inferior physical condition, because the soil is continually a good nidus for the plant, and the roots can always readily ramify through it in search of food." Sir John Lawes says with reference to his own great work: "All our experiments tend to show that it is the physical condition of the soil, its capacity for absorbing and retaining water, its permeability to roots, and its capacity for absorbing and radiating heat, that is of more importance than its, strictly speaking, chemical composition."

-We have now seen the value of roots in maintaining the physical condition of the soil. To further extend our view of their importance,

we must next consider the value of roots of certain classes of plants for bringing up nitrates, ash constituents and moisture from below, and look upon them besides as sub-soil ploughing agents.

With certain crops (parsnips) it is found that though the land was worked only a foot deep, that the soil immediately below the part dug is in finer physical condition than the cultivated land above, due to the roots penetrating and minutely subdividing the hard subsoil. We give another illustration from India, where the same result is seen when forest gradually extends itself into adjacent grass land, and the roots of the trees permeate the land below the roots of the grass, and so turn the whole soil to a considerable depth into beautiful cultivated condition. Again, agriculturists in France, in order to improve certain arable lands, are known to sow on them a mixture of gorse and grass (to be cut for hay) with a view to improving the depth and texture of the soil which after some years is again ploughed up. We have now taken account of (1) the action of roots in dis-integrating the soil, and (2) their power to act as subsoil ploughs, and so to enable the roots of grasses and clover, and other plants, not only to supply themselves with moisture from great depths in the soil, but also to retrieve and bring to the surface nitrates and ash constituents which are far beyond the reach of ordinary plants at present used in agriculture, and thus, I need hardly say, add enormously and without any special outlay, to the manurial resources of the farmer. We have lastly to consider the direct manurial action of roots as they decay in the soil.

Humus, or decayed vegetable matter existing in the soil, is well known to be one of the most important constituents in all fertile soils, and it is this which largely gives great value to newly-cleared forest lands and freshly broken up old pasture. Through two agencies of cultivation, cropping and drainage, it is gradually partly consumed and partly washed out of the land, and I think I am correct in saying that, in the opinion of our most experienced agriculturists, one of the greatest difficulties is the exhaustion of the soil, mainly arising from the decline of this most necessary agricultural agent. And this is proved by the fact that if we put back on the soil as large an amount of vegetable matter as it contained originally, the poorest soil, will again and for some years, produce good crops, with the addition of little or no manure.

SCIENTIFIC MANURING. COCONUTS.

Communicated.

It will be a happy day for Ceylon when manuring is carried on generally on scientific lines. If we find a friend use a manure with satisfactory results, we take it for granted that it will yield like results if we use it ourselves, quite regardless of any difference there may be in the soil. We have not advanced sufficiently far in the path of agricultural progress to employ a chemist to analyze and report on our soils before

we use any manures. So far as the tea industry is concerned, thanks to Mr. Hughes, a complete analysis of the tea plant enables planters to apply manures to replace the elements of fertility removed by a tea cup.

Coconut planters unfortunately are not so highly favored. They do not count amongst their members men of sufficient progress who have a complete analysis of the coconut tree, and they have no Association to undertake what the individual has not the public spirit to do. "All about the Coconut Palm" has a series of analyses undertaken by Mr. Lepine of all parts of the coconut tree. The correctness of this table of analysis was taken for granted till Mr. Cochran recently undertook the analysis of the husk of a coconut. The disparity between his figures and those of Mr. Lepine was so startling as to shake confidence in all the figures of the latter. With this single reliable analysis of the husk, a system of scientific manuring for coconuts is recommended. This may strike one as not very scientific, but it is the best course to follow under the unfortunate circumstance in which coconut planters are placed, or rather have placed themselves.

Messrs. Freudenberg & Co. have with praiseworthy enterprise introduced into our market the chief manures which have been known to yield good results, and which are in general use in European agriculture, and they have with equal enterprise enlisted the services of Mr. Cochran to introduce them to the public with analyses of their composition and essays on the methods of applying them.

In Mr. Cochran's analysis of the husk of a coconut grown by the sea-shore, he found salt the dominant mineral constituent. He is not sure whether on this account he should recommend its application to coconut trees with other manures. It will be safe for him to do so, especially in situations removed some distance from the sea, and where in consequence the tree is not grown under natural conditions. On sandy, non-retentive soils it will be best to apply salt in grains on the surface of the soil towards the end of each monsoon. In the absence of reliable analyses of the products of the coconut tree, the plant food contained in manures, the application of which is known to yield good results in most soils, is taken as a basis to calculate the manurial ingredients of a coconut tree.

Nitrogen	...	1	lb.
Phosphoric Acid	...	1.25	"
Potash	...	$\frac{3}{4}$	"

Thomas' Phosphate Powder being more soluble than the phosphate in bone meal, Mr. Cochran has thought fit to reduce the quantity of phosphoric acid in the mixture he recommends. Whether this is wise is a question. Perennials do not want so highly soluble and readily available manures as annuals. What the latter fails to take up during its limited life means in the first place a corresponding shortness of crop, and secondly a pecuniary loss. Chemical research has proved that drainage water has been found to contain manurial substances in solution. Not so with perennials, especially with the vast network of roots of the coconut palm. Hardly anything goes to waste. Everything is greedily sucked up. And

too readily available manure stimulates the tree to too heavy bearing and the natural reaction follows. For the cocconut palm the available plaut food ought to be continuous. The quantity of potash for each tree has been increased and rightly. The mixture recommended is:—

Castor Cake ...	15 lb.
Phosphate Powder...	3 "
Sulphate of Potash ...	2 "
which is equivalent to	
Nitrogen...	1.05 lb.
Phosphoric Acid ...	1. "
Potash ...	1.18 "

This dose is to serve for two years, but if husks are removed for the estate 1 lb. of Sulphate of Potash ought to be added in the year following the application. Not knowing the price of Sulphate of Potash, Mr. Cochran cannot say whether it will be more economical to sell husks and buy and apply Sulphate of Potash or to burn the husks on the estate for the Potash they contain. Only few estates are so situated as to be able to sell their husks, and whether it is wise even for them to do so is a question, for according to Mr. Cochran's own analysis the ashes of husks contain besides Potash, Salt, Phosphoric Acid and Lime, all very valuable manurial agents.

KAINIT.

This is a Potash Salt that Mr. Cochran expects to yield very good results when applied to cocanuts:—

	COCONUT HUSKS.		KAINIT.
Potash ...	31%	...	12.8%
Salt ...	38 "	...	34. "
Magnesia...	3.6,	...	10. "

As the other products of the cocconut tree do not contain so much Potash as the husk, Mr. Cochran is of opinion that Kainit will be found to contain sufficient Potash for the requirements of the tree. As one ton of Sulphate of Potash has as much Potash as 4 tons of Kainit, the question is suggested as to whether it will be cheaper to apply the one or the other. Four tons of Kainit has, besides the Potash it contains, 1.28 tons of common salt, a very necessary manure for cocanuts. To form an opinion one requires the relative prices of the two manures. To price will have to be added transport of 3 tons extra and cost of application of same. Where transport is concerned, the more concentrated a manure is the better. No fear need be entertained about Kainit containing salt in excess of the actual requirements of the cocconut tree as indicated by analyses, and no necessity will arise to balance it by the addition of Sulphate of Potash. The natural conditions under which the cocconut palm grows, on the salt-saturated soil of the sea-shore and in an atmosphere heavily laden with salt, should not be forgotten. Besides, salt plays a very important part in altering the chemical and mechanical condition of soils.

CALOTROPIS GIGANTEA.

This plant known in India as Madar or Mudar, and among the Sinhalese as *wara*, is the subject of investigation by Messrs. Macdonald, Boyle & Co., the patentees of machinery for treating ramie

fibre. The bast fibre of the wara has attracted considerable attention in the past, and has been often referred to as one of the best of eastern fibres. The difficulty so far has been the inability to rapidly and cheaply separate and clear the fibre. If the ramie fibre machinery is found to do this as well as it has proved to do with ramie itself, a great success will be attained, and the wara which is a hardy weed in many parts should prove a dangerous rival to ramie.

Mr. Liotard, who has devoted much time to the study of Indian fibres, has, however, expressed a very unfavourable opinion with regard to Calotropis fibre, and that on two grounds, (1) the small percentage of fibre, and (2) the shortness of the fibre. Other observers, curiously enough, are loud in praise of it. The following statement contains the results of Dr. Wight's experiments as to the comparative strength of the fibre:—

Name of Fibre.	Weight in lb. the fibre can sustain.
Coconut... ..	224
Hibiscus Cannabinus ...	290
Sansiviera Zeylanica ...	316
Cotton	346
Agave Americana	362
Crotalaria Juncea	407
Calotropis Gigantea	552

A decided recommendation for Calotropis is the fact that it is not particular about the soil in which it grows, and flourishes in poor dry sandy situations as is well seen along the seaside railway line. It has been suggested that the plants should be employed to reclaim waste lands with poor soil.

In India the leaves and twigs are much sought after as a manure for paddy-fields, and wet lands so manured are found to yield a much superior crop. Another use to which the herbage is put is to reclaim lands impregnated with salt. The decomposition of the leaves somehow or other "kills the salt" as the natives say. So that in growing the plant for fibre, if nothing but the fibre be removed off the land and the leaves and rejected parts of the stem be returned to it, there should be little exhaustion of soil. As regards the value of the floss or silky coma got from the pod there has been much speculation, but Dr. Watt mentions that at the time of the last Indian and Colonial Exhibition held in London, he had an opportunity of discussing with manufacturers the prospects of Mudar floss, and that a Lancashire spinner had declared that he had completely overcome the difficulties offered by this floss and was prepared to purchase any quantity. The spinner referred to is said to have put some money into the hands of a missionary for the experimental cultivation of a few acres. Dr. Watt reports that the results have been encouraging, and hope is even held out that by careful selection of seed and attention to cultivation it might be possible to change the character of the floss and improve its length. Mr. Cameron of Mysore states that a demand has lately arisen for Mudar floss, Messrs. Collyer & Co., of London, offering 5d. a lb. for it.

In 1895 a letter from Messrs. Thirkell & Co., London, addressed to the editor of the *Observer*, was published in that paper, and there the

following passage occurs:—"In conclusion we would ask for samples of the silk cotton or flax from the seed-pod of the *Calotropis gigantea*, or Mudar for which a demand appears to be springing up again, present value about 6d. per lb. landed in London." Among the other products of *Calotropis gigantea* may be mentioned a dye, gutta-percha, liquor and "manna," and wood for charcoal, while the medicinal properties of the lant are well known and widely reputed.

DR. WATT ON COCONUT OIL.

While a brief abstract has been given of coconut oil, it is necessary to deal with this subject in greater detail. Enquiries are frequently addressed to the Government of India by merchants interested in the trade in this substance, so that it has become necessary to put on record as complete an account as can be collected from the scattered publications that exist, even should that prove but a statement of the littleness of our knowledge. One of the earliest, and to this day the most satisfactory descriptions of the Indian coconut oil industry is that written by Lieutenant H. P. Hawkes, and published in 1857. Gazetteer writers have contented themselves with treating the subject as too well known to call for any detailed description, and at most only the meagrest accounts have been given to the merchant desirous of starting a new or extending an existing trade, the question of primary importance to which he calls for a reply being the province or district with which he should open up dealings. The chief products of the coconut are coir fibre, oil, and toddy, or the juice from which sugar and spirits may be prepared. We know that in Bombay the juice is largely extracted from the tree, that in Mysore the fibre is the chief preparation, and that in Madras and Travancore enormous quantities of both fibre and oil are exported; while Bengal, on the other hand, imports immense numbers of coconuts and a large quantity of copra, but exports very little of the products of the palm. It can nowhere, however, be discovered whether any two of these primary products, or all of them, can be derived from the same trees or even prepared by the same cultivators—certain plants or portions of the plantation being periodically set apart for these several industries. Under coir fibre it has been said that green or unripe coconut is alone used for that purpose, while most writers seem to agree that the ripe kernel is necessary for the oil. It would be most instructive to know if cultivation had resulted in the production of certain races of coconuts famous for their oil-yielding properties, just as the inhabitants of the Laccadive Islands appear to have developed a small fruited one with a specially good fibre. In connection with commercial reports on coconut oil it is generally stated that the finest qualities are obtained from "Cochin." (Spon places Cochin after Ceylon.) It will be recollected that this same statement occurs regarding the fibre derived (or supposed to be derived) from that Native State. The writer has failed to discover any account of the Cochin oil industry, and is almost

forced to the opinion that by "Cochin coconut oil" as with "Cochin coir" may be meant the superior qualities of the oil derived from the Madras Presidency. If ripe coconuts are essentially necessary for the preparation of the oil, then the Maldive and Nicobar Islands might be looked to as the great seats of the oil industry. But while these islands export perhaps little short of from 15 to 20 million ripe coconuts a year, they do not appear to manufacture coconut oil, and the ripe husks are of no use for fibre. So, in a like manner, the Laccadives would not be looked to as a source of oil; these islands are famous for their coir, the inhabitants growing a peculiar coconut that would seem to be inferior to the Malabar either as an oil-yielding or an edible nut. The imports from the Maldives and Nicobar Islands into Madras are very unimportant as compared with those recorded against Bengal, yet Madras, and not Bengal, appears to control the coconut oil market. This fact would lead to the inference that the locally-grown nuts of Madras were largely employed for the expression of oil—the very considerable imports from the Laccadives affecting mainly the coir industry. But if this inference be correct there remains the difficult position that the ripe nuts, serviceable for oil-making, yield no fibre. The presumption would therefore appear to be that a very much larger amount of the Madras coir comes from the Laccadives than we have any definite knowledge of at present, or that a large preparation of the coast coconuts or those of certain localities only are always or periodically set apart for oil-yielding. It may, of course, be the case that the trees are, so to speak, pruned by the removal for coir of so many green nuts from each tree, the remainder being allowed to ripen for oil purposes or as articles of diet.

This brief review, from want of definite information, may be accepted as indicating the direction that future reports might assume; but it may safely be concluded that, as with coir, so with coconut oil, Madras is the chief seat of the trade. Certain writers familiar only with Bengal (with the waving feathery clumps of coconuts dispersed through its suburban jungles or surrounding its mango topes) have advocated the claims of the Lower Provinces as a future region of oil-production. This would appear to be a pure hallucination which the enormous imports of ripe nuts should have prevented. It is extremely doubtful if Bengal is ever likely to do more than meet the local and internal demand for ripe nuts and oil. The European oil merchant, if he finds the suggestion impracticable which has been offered in an early paragraph, viz., to call in the aid of the Maldive and Nicobar Islands,—will do well to concentrate his attention on the Madras Presidency.

BANDAKAI FIBRE.

Enquiry has been made through the *Ceylon Independent* as to the possibility of extracting fibre from the plant locally known as "Bandakai" (its botanical name being *Hibiscus esculentus*),

and we therefore give the following references to the subject:—

The bast yields a strong useful fibre of a white colour, which is long and silky, generally strong and pliant, and composed of very strong individual fibres. It is employed economically in some parts of India, but in many districts where the plant is much grown as a vegetable, the excellence of the fibre seems to be unrecognised. It is undoubtedly valuable and seems to possess qualities specially fitting it for the purpose of paper-making. According to Roxburgh its breaking strain is 79 lb. when dry, 95 lb. when wet. It contains 74 per cent of cellulose, and in Messrs. Cross, Bevan & King's experiments it was found to lose 9.8 and 14.2 per cent of its weight when boiled in 1 per cent solution of caustic soda for five minutes and one hour respectively. The average yield of fibre by Death and Ellwood's process was found to be 84½ lb. per acre, while by retting it amounted to 6 maunds and 17 seers. (The acre yield of fibre by the same process from *Hibiscus abelmoschus*, Sinhalese "Kapu Kulisssa" was 800 lb. by retting 12 maunds and 17 seers; the average breaking weight of the fibre whether wet or dry being 107 lb.). Liotard in his *Paper-making Materials of India* notices the fibre, mentioning that it is very fine and well suited for paper making, and in another passage says that paper has been made with it, though only on a small scale, in the Lucknow Central Jail.

In France the manufacture of paper from this fibre is the subject of a patent; it receives only mechanical treatment and affords a paper called *banda*, equal to that obtained from pure rags. In Burma, Madras and other parts of India, the stem is allowed to rot unused. This valuable fibre which could thus be obtained very cheaply does not appear to attract the attention that it merits. (*Dr. Watt.*)

The okro (*Hibiscus esculentus*) has long been known to yield a long silky fibre. Specimens of Indian okro fibre in the Kew Museums resemble hemp in colour and texture. It is evidently well adapted for making ropes, twine, and sacking, while the residual portion can be utilized for paper-making.

Recently the preparation and use of okro fibre has been revived in the Southern United States, where the plant is largely grown during the summer season, and also in Cuba. In a report by Mr. Consul Ramsden the following information is furnished: "The fruit is well-known in the English West Indies under the name of 'okra' and is used as a vegetable, but although Pichardo, in his 'Diccionario de Voces Cubanas' mentions the plant as being applicable to rope making, I am unaware that it has been used as a fibre, and, therefore, refer to it here. Last year Messrs. Bosch & Co., of this city, made an experiment with some, and sent 400 pounds of the dried fibre to London, where they say it was much liked, and found to be worth £40 per ton. Three crops are obtained in the year, and its preparation by maceration gave very little trouble. The stem produces a fibre of fine quality, and about 4 feet in length, and apparently strong. Further trials will probably be made here. I send sample of it with this

report." With regard to the commercial value of this Cuban fibre, Messrs. Ide & Christy of 72, Mark Lane, E.C., to whom it was referred reported as follows: "The sample shows the fibre to be only moderately stronger than jute, imperfectly cleaned and very yellow in colour. We value it at £18 to £20 per ton today in London. It is possible that the colour could be greatly improved by more careful preparation, and that in that case its value might be increased by £4 or £5 per ton. We cannot imagine it possible that fibre of this type could have been found worth £40 per ton last year in London as stated to the Consul and mentioned in his report." (*Kew Bulletin*, No. 46.)

We find the following reference made by us to Bandakai fibre in our issue of September 1893: Within the past few years, says the *Auckland Weekly News*, much attention has been given to okra as a fibre plant in the Southern States of America. Mills are said to have been erected in England as well as in Germany and France by a Mr. Sadlow, for working up the raw material, which he says he can produce at ½d. per lb. This information came originally from an American source, and may of course be overdrawn, but one fact is clear, and that is that the fibre referred to is a valuable one and its production, cost and value are worth careful enquiry. In an official report on the cultivation of jute and other fibres, *Hibiscus esculentus* is referred to thus: The fibre is harsh and brittle for which reason it is not manufactured to any large extent in Bengal, but in Myren Singh and Dacca it is occasionally prepared for adulteration with jute. The defect in the fibre it would seem is due to the process adopted in making it, for in the Southern Presidency it is so manufactured as to retain considerable strength and pliancy, well-suited to the manufacture of rope, string, gunny bags and paper, and bearing considerable resemblance to the true hemp of Europe. The quantity prepared annually is large, and there is an exportation calculated many years ago at between 6,000 and 7,000 cwt., and valued at between £27,000 and £28,000.

SERUM INOCULATION FOR RINDERPEST,

Of the two methods recommended by Prof. Koeh—the serum treatment and the bile treatment—for inoculating cattle with the object of rendering them immune against rinderpest, it would appear that the former will prove to be the most effective. Space does not admit of our referring to the difficulties which stand in the way of carrying out Koeh's method of treatment with bile, or of describing Dr. Edington's improved method of using glycerinated bile (both of which when properly carried out have without doubt been the means of saving much loss of life), but we must not omit to quote the important communication made by the Colonial Veterinary Surgeon of the Cape with reference to the serum treatment:—

Professor Koeh, in the early stages of his experiments at Kimberley, verified the fact already discovered, that serum obtained from salted cattle gave an immunity from rinderpest when injected

in large doses of 100 c.c., but that immunity conferred was only "passive in its nature and temporary in its effects." In order, therefore, to increase the immunising power of the serum, and at the same time reduce the necessity for so large a dose, he added to it 1 per cent. of rinderpest blood. This mixture acted more satisfactorily, but at that time he considered that it was neither so safe nor so effective as the gall obtained from sick animals. Contemporaneously experiments with serum were conducted conjointly by the chief veterinary surgeons, Mr. Pitchford, of Natal, and Mr. Theiler, of Transvaal, on similar lines. Since then Drs. Danysz and Bordet, the French scientists, have devoted their attention principally to the perfection of the serum method of treatment both as a preventive and curative agent. As they express it, "their main object was to procure a serum which could be successfully applied to a herd in which the disease had already made its appearance, and where the employment of methods which brought on the disease in a light degree could only aggravate the condition of the animals already affected," and the results of their numerous experiments show that this object has been attained.

With respect to the manner in which herds inoculated with serum should be treated, they say: "It is known that the blood of salted oxen does not give permanent immunity from rinderpest, but that animals injected with this blood acquire the property for a limited time of withstanding the attack of the disease more easily. If they are brought in contact with rinderpest after the injection with blood, they contract the disease but recover, and become salted. When the animals are already sick, or if they already possess the germs of rinderpest at the moment of injection, nothing else remains to be done than to inject blood to make the disease less serious for them. On the other hand, the animals that are not affected by rinderpest at the moment of injection must become infected, so that they can catch the disease in a light form which the blood will help them to get through, but which is also sufficient to thoroughly salt them. Rinderpest can be transmitted either by allowing the animals to mix with sick oxen, or by injecting rinderpest blood, and it must be known which of the two means is the better. We are convinced from the trials that infection solely and exclusively developed through rinderpest blood cannot be regarded as good, as it is impossible—within the range of our knowledge—to apply it in practice in such a manner as to obtain good results."

From the foregoing it will be observed that the principal advance which Drs. Danysz and Bordet have made in the application of the serum treatment to rinderpest consists in the method which they have devised for communicating the infection to the serum-inoculated cattle; so that they contract a modified form of the disease from which they recover and become salted. Other scientists, but principally Semmer, Neucki, Sieber, and Wyznikiewicz, had previously discovered that the serum of animals which have recovered from the pest has immunising properties, but these experts trusted to repeated injections

of the serum while the animals were liable to the disease rather than to one large injection followed by immediate exposure to infection, so that the inoculated animal should contract a mild form of the disease at once, under the modifying effects of the serum, from which they would recover. This is the most important point in Drs. Danysz and Bordet's application of the serum method of treating rinderpest.

It has to be noted, however, that these French experts do not consider the serum treatment so suitable for dealing with clean herds as with herds already infected, or herds which can be exposed to infected animals immediately and continuously after inoculation. They say: "The injection of small quantities of rinderpest blood into animals that have been previously inoculated with the blood of salted animals is not sufficient to infect a beast in such a degree as to secure for them a continuous salting after the cure. . . . To attain a good result a carefully regulated quantity of blood must be injected, large enough to occasion a small degree of sickness, small enough to guard against serious sickness or death. But the correct measure of such a quantity of infected blood cannot be determined in practice, as it depends on how much strength the preventive blood previously injected possesses. Two samples of preventive blood never have the same strength. . . . It happens differently with animals which have received an injection of preventive blood, and coming into contact with animals infected with rinderpest immediately afterwards. Such animals always get an attack of rinderpest, which is not deadly, when the preventive blood used is good, but which is sufficient to well salt the beast." Further, if healthy animals which have been inoculated with preventive blood or serum are exposed to infected cattle immediately and continuously afterwards, it is of little importance whether the dose of serum injected is unnecessarily strong or not, so long as it is sufficiently strong to give complete immunity at the time; because the subsequent infection being continuous each animal contracts a mild form of the disease as the strength of the immunity conferred by the serum gradually admits. This cannot be accomplished satisfactorily by an injection of rinderpest blood, which has to be made at a definite time after the serum inoculation, because if the dose of serum is very strong the majority of the animals may resist the after-blood inoculation and manifest no signs of fever, and consequently will not become salted. On the other hand, should the dose of serum be comparatively weak, and the after-blood inoculation be too long delayed, the animals inoculated would be liable to contract a virulent form of rinderpest, from which many would die.

In like manner if a healthy herd of cattle is inoculated with a strong dose of serum, and at the end of 24 hours they are driven in amongst an infected herd, and kept there from 12 to 24 hours and then withdrawn, this has been found to give very unsatisfactory results, because during the short exposure many of the inoculated cattle did not contract the disease but caught the infection subsequently from their companions (since the immunity had passed off by that time) and died of

virulent rinderpest. Experience indicates therefore that the plan which gives most promise of success is to inoculate with a large dose of good serum or defibrinated blood obtained from a salted animal which has been fortified by several injections of rinderpest blood, and to expose the inoculated cattle immediately and continuously for several days afterwards, until every one has contracted a mild form of disease from which very few will die. While this is the position at present, "we have every hope," says Dr. Hutcheon "of being able to devise a method by which clean herds which cannot be exposed to infected cattle may be successfully inoculated with serum. Drs. Turner and Kolle have recently been directing their attention to this matter, and in a telegram which I received from these gentlemen on the 8th inst. (Sept.) they state that "there is no longer any doubt that the best way to immunise cattle is by injecting into them one cubic centime of virulent blood, and directly after infecting them with serum." Should their confidence in this matter be confirmed by extended experience, the inoculation of healthy herds with preventive serum will become a comparatively simple matter, which it is not at present."

Dr. Hutcheon cautions cattle owners against the indiscriminate use of serum; for it is a mistake to think that to bleed a salted animal and inoculate healthy stock with the blood is all that is necessary, since the result will be useless and disappointing.

FRUIT CULTURE.

Let us suppose that the land intended for the orchard has been thoroughly broken up and converted into mellow well-aerated soil, and the drains also laid out in the manner described. Open drains are in many ways objectionable; they are so much space wasted, the side-slopes inevitably become gardens of weeds and harborers for pests innumerable.

The next consideration is the laying out and locating places for the trees. The question of how many trees to put to an acre, is one about which there are many opinions. The question, however, should not be "How close can I stick my trees without being considered mean to them?" but rather "what distance apart would be best for their healthy growth?" The tendency is naturally to put them far too near each other, because they come to the ground as mere plants and we have little idea of the proportions to which they will grow in 5 or 6 years. It is best to remember in allotting the space that the foliage-head of two adjoining trees must go halves for the space between them: and what is true of the branching head is also true of the branching roots which must share the feeding ground between them. The smallest distance which can be allowed between tree and tree is 20 feet; set squarely, this will give 109 trees to the acre. The more liberal allotment of 22 feet apart, giving 90 trees to the acre, will probably pay better in the long run. The device of planting by which any one tree in a row is between two trees of the next is now universally adopted as the best. The underground feeding

space of the roots is thereby more evenly divided, and the effect of high wind much diminished.

In planting, the holes should be dug out before beginning, one among other advantages being that the earth thrown out is all the better for being exposed to the sun and air, and particularly so where the land is inclined to be heavy. It is best for two men to attend to the actual planting out of the trees. A little of the upcast earth should be thrown into the bottom of the hole and the soil is then loosened up by a chopping action. More earth is then added until it is found by trial that the tree will sit easily on the loose contents and the collar stand a little higher than the level of the surface in which the hole has been dug. The contraction of the filling will take up that surplus and leave it true. The roots are then carefully looked over, all broken roots are cut off with a sharp sloping cut facing downwards, and the fibres distributed evenly upon the cushion of soil in the hole. They must be divided evenly around the circumference of which the stem is the centre. Little by little the attendant should shovel in small quantities of loose earth, and this is packed and worked in by the planter's hands, so that close contact, and above all the absence of hollows, may be ensured. At the same time the planter should see to the accurate setting of the tree both for line and uprightness. Then both men shovel in the earth to the surface. Neither immediately on the roots nor even on the surface soil is there any need for the ill-considered tramping and jumping which is often practised. The contact of earth and root system should be firm yet gentle. The ramming in of earth which may be necessary when planting a post will not do when dealing with a living organism from which we expect delicate rootlets to grow and for which we desire to prepare a suitable feeding ground. It is far better to manipulate the first additions of soil around the roots should be by the hands instead of the foot, so that the proper degree of firmness and closeness may be insured without losing the open texture of the soil. Then even if rain is falling at the time the final operation must be watering, and from 1½ to 2 gallons of water, according to the size of the hole, should be gently and slowly poured in through the rose of a can. It will not do to slush it from a bucket. The effect desired is to settle the particles of soil finally in their places and establish average and equal pressure round the root. A sudden dash of water will convert the top and layer into mud which will dry into an impervious caked surface, whereas after watering the soil round the tree should be as open and porous as before. If the time could be chosen, the planting should be done in cool overcast weather, without bright sunshine or much wind. In a few days' time the callusing of the cut roots should be over and new white feeding fibres spring forth. Then the tree will have caught on to its new situation.

PRESERVATION OF GRAIN BY WEEVIL.

(Note by Prof. Churck.)

The only cheap and perfect application of the prevention of the attacks of weevil upon

corn and grains consists in the employment of bisulphide of carbon. The quantity required, provided the grain is kept in closed vessels, is very minute—not more than $1\frac{1}{2}$ lb. to each ton of grain—so that 8*d.* is the cost of preserving a ton of wheat. The bisulphide leaves no disagreeable taste or smell behind, and the quality of the grain remains unimpaired. When bags are used instead of the iron cylinders specially prepared for use in the bisulphide process, the protective influence of this chemical soon ceases, and a fresh application of the bisulphide must be made. In either case the liquid is applied as follows. A ball of tow is tied to a stick of such a length that it can just be plunged into the middle of the vessel containing the grain. The tow receives the charge of bisulphide like a sponge and is then *at once* plunged into the sack or cylinder and left there, the mouth being closed tightly. When necessary the stick may be withdrawn and the charge (1 oz. bisulphide to 100 lb. grain) renewed.

(Note by F. W. Cabaniss, Asst. Director of Agriculture, Burma, on the Prevention and Destruction of Black Weevil.)

I have been trying for several years a number of experiments, with the object of finding a cheap and simple method of preventing the ravages of this weevil. I think that I have found it in the use of naphthalene powder. My method of using the powder is here given for the benefit of the grain dealers of Burma. It is best to place the naphthalene powder at the bottom of the bin or bulk of grain. To accomplish this take a bamboo, about $1\frac{1}{2}$ inches in diameter and long enough to reach from the top to the bottom of the bulk of grain. Punch the joints out of the bamboo, so as to be able to pass a stick through from one end of the bamboo to the other. Have the stick made to fit the cavity in the bamboo. Pass the bamboo, with the stick in it, down through the bulk of grain from the top to the bottom. Withdraw the stick, and drop into the top of the bamboo about half a teaspoon of naphthalene powder. The bamboo can then be drawn out, as the naphthalene is safe at the bottom of the bulk of grain. If the bulks are large this should be done once to every 10 feet square of the bulk. Repeat the application every 15 or 20 days as the powder evaporates.

The weevil that can leave the grain will do so, and those that cannot leave are killed by the odour of the naphthalene. I do not believe that naphthalene thus used can cause any injury whatever to grain. For seed purposes the germinating powers appear not to be affected in the least. For marketable grain the colour is not affected, and the odour will leave in a short time if fresh naphthalene is not applied to it. The quantity of powder used is infinitely small in proportion to the quantity of grain, and the powder is entirely destroyed by evaporation, so that for food purposes the effect is *nil*.

Naphthalene powder can be procured at the Medical Halls in Rangoon at Rs. 2-8-0 per ounce, and a few ounces of it will be sufficient for one season for any grain dealer in Burma.

[There are two species of weevil (*Curculionidae*) belonging to the division *Rhyncophora* which attack stored wheat and other grain. One is *Calandra (Sitophilus) Granaria*, and the other *Calandra (Sitophilus) Oryzae*. The former is found principally in Europe America and Canada. The latter which requires a high temperature is chiefly confined to India and other hot climates.]

GENERAL ITEMS.

Good coca leaves yield 75 per cent or more of cocaine, but the average is less, and if fermented often *nil*. The London market price of cocaine in July 1897 was 9*s.* 3*d.* to 9*s.* 6*d.* per oz. Great care must be taken in the gathering, drying and preservation of cocoa, as its activity and value depend in a great measure on its mode of preparation. The leaves should be gathered as soon as they have arrived at maturity, at which period they are bright-green on the upper surface, and yellowish green on their under surface, and have an agreeable and somewhat aromatic odour. The leaves are gathered separately and carefully by hand with the two-fold object of preventing them from being crushed or bruised in the process, and also so as not to injure the young leaf buds which are left behind for the purpose of obtaining a second crop of leaves. They are then spread out and dried slowly in the sun. The operation must be performed with great care, for if the leaves be dried too rapidly, they lose their odour and green colour; and if stored before they are thoroughly dried their colour is also changed, and they acquire a disagreeable odour and taste. Commercial coca either consists of the leaves more or less pressed together in compact masses or of the leaves in a loose state. In either case the leaves are not curved or rolled in any degree, but perfectly flat. The properties in the leaves are injured by transportation and often by keeping; they should therefore be packed in tin-lined cases.—(J. F. Bailey in the *Australian Tropiculturist*.)

Hygrroryza aristata (Sin. Gojabba) is what is commonly known as "wild rice." It is an aquatic grass found floating on the surface of water or creeping on wet land. The grain, which in India ripens in September, is there eaten by the poorer classes who collect it by sweeping the heads of the grass with baskets. According to Roxburgh, cattle are fond of the plant. We have not heard of the grain being consumed in Ceylon.

There are three varieties of gingelly (*Sesamum indicum*) from which oil and poonac are got, viz., the white, black, and red-seeded varieties. All are extremely rich in oil, but especially the first mentioned. According to analyses Dr. Leather, Agricultural Chemist to the Government of India, white gingelly contains 48.13 per cent of oil, black 46.50, and red 46.20 per cwt. of oil, while the percentages extracted by the country mill were 38.1, 30.9, and 30.9 respectively.

Artificial Indiarubber, the most recent product of the laboratory, which is a mixture of

rape oil and sulphur dried down to solidification, though to a certain extent successful, has not by any means the requisite durability.

It has been well-known that a solution of iron sulphate has long been employed for the destruction of ground mosses which overrun plantations during damp weather. It has also been found that the same solution will cleanse the trunks and branches of trees of the numerous lichens which infest them, and may also be employed with success against the numerous colonies of *Agaricus campestris* (the common mushroom) which spring up in cultivated spaces. This peculiarity of iron sulphate has led to new efforts being made with it against parasitic fungi on plants in general.

On orders received from the Viceroy of India, Messrs. Carter & Co., the well-known seedsmen, shipped no less than 108 tons of carrot seed, which were collected and despatch within

nine days of the receipt of the Viceroy's telegram ordering the seed. The original order was, however, for 200 tons at a rate not exceeding £80 per ton delivered in Bombay. The seed which was brought over during the famine crisis was deemed sufficient to sow about 42 square miles of land.

There is a demand for cow-pea seed among the Queensland sugar growers who have come to recognise the merits of the plant as a nitrogen gatherer. Of leguminous crops the cow pea matures most rapidly and occupies the ground at the shortest time, and produces perhaps the greatest amount of nitrogen. When grown and ploughed into the land just before it reaches maturity, a manure is thereby added to the land containing about 100 lb. of nitrogen, equivalent to that produced by the addition of 4 cwt. of sulphate of ammonia or 8 cwt. of dried blood per acre.

[No. 7.

BUITENZORG BOTANICAL GARDENS, JAVA: A LESSON TO INDIA AND CEYLON.

We have to acknowledge receipt of copies of "Hand-Guide to the Botanic Gardens, Buitenzorg with a plan published under supervision of the Director in Batavia, by G. Kolff & Co., 1897"—all printed in English

and all very interesting. It includes besides the "introduction," a walk through the Botanic Gardens; a visit to the Agricultural and Experimental Gardens (which we must copy in full into our next *Tropical Agriculturist*); and "an index of scientific and vernacular names." The Guide is clearly modelled on the one drawn up for Peradeniya by the late Dr. Trimen; but the Java Gardens are far more diversified—although the Buitenzorg Botanic Garden itself at 145 acres is almost exactly the same area as Peradeniya which includes 150 acres. The Dutch Director has, however, a virgin forest reserve of 700 acres, as may be seen later on. Meantime we transfer the introduction as follows:—

The Botanic Gardens at Buitenzorg were established in April 1817, at the suggestion of Reinwardt, who was afterwards a Professor at the Leiden University. During Reinwardt's stay in Netherlands-India there was no special director for the new hotanical establishment, he took over the superintendence himself. On his departure from Java Dr. C. L. Blume was appointed the first Director of the Buitenzorg gardens.

Blume proved to have remarkable abilities for natural science; in a short time he got great renown as a botanist and so the gardens seemed to have under his direction, a very satisfactory prospect. But, after a stay of four years, Blume was obliged to go home on account of his bad health; there was no director appointed as his successor, the gardens were left in charge of a curator.

The curator James Hooper, an able man, who came originally from the Royal Kew-gardens, returned to Europe in 1830. A young gardener just arrived with a new Governor-General was selected as his successor.

The young man's name was J. E. Teysmann; devoid of the slightest scientific notions, lacking even ordinary general instruction, and having had but a very superficial training in horticulture, he seemed rather an unqualified person for filling up the post of curator. Happily the Buitenzorg gardens belong to the institutions which have good luck. Teysmann turned out to be a most energetic man, with a bright intelligence and greatly gifted for natural science. By self-training and hard work, guided by a clear insight and supported by a keen aptitude for organization, he became, in fact, a second founder of the gardens, with which his name will always be inseparably connected.

In the course of his career as a curator Teysmann was assisted by two very clever men, J. K. Hasskarl, and S. Binnendyk. Hasskarl, afterwards famous as a botanist, was the man who suggested a new plan for the gardens, in order to have all the plants, even the trees and shrubs arranged after the natural system. That idea, once grasped by Teysmann, was pushed by him, often under great difficulties, with fierce energy. The arrangement after the natural system, in some parts already sixty years old, constitutes now one of the prominent features of the Buitenzorg botanic garden. It makes it still comparatively easy to study the plants and especially to compare the species belonging to the same natural order, though the number of species under cultivation is now some 10,000, covering an area of 145 acres.

Binnendyk was appointed assistant-curator in 1858. His services were of great value, not only because he was a very able horticulturist, but also because he had had a fair training in systematic botany at the Leyden hotanic garden. And so as Teysmann resigned (in 1869) Binnendyk was of course, selected as his successor.

In the mean time the whole institution was re-organized, on a plan drawn up long before by Teysmann.

There was to be a Director again, and it was Dr. R. H. C. C. Scheffer who in 1868 was appointed the second Director of the Buitenzorg gardens. Having made thorough studies in botany under Miquel's direction at the Utrecht University Dr. Scheffer although young, was well prepared for the post. Devoting as much of his time as possible to research and original scientific work, he had the good idea of starting in 1875, the *Annales du Jardin Botanique de Buitenzorg*, a scientific periodical still existing. Beyond all other things the Buitenzorg establishment is most indebted to the late Dr. Scheffer, for establishing, in 1876, a special garden, on a large scale (an area of more than 180 acres) for agricultural and experimental purposes. He added also an agricultural school to this experimental garden. This school lasted only a few years. Without time to go on furlough to Europe to restore his health, Dr.

Scheffer died, of overwork, in the beginning of 1880, only 36 years old.

Dr. Treub was selected as his successor. This gentleman, who has been in charge since 1880, still continues the extensions begun in 1876 by Dr. Scheffer.

The institution still called "s Lands Plantentuin" consists of the following nine Divisions:—

- Division I. Herbarium and Museum.
- II. Botanical Laboratories.
- III. Agricultural and experimental garden (181 acres) with Laboratory for agricultural chemistry.
- IV. Pharmacological Laboratory.
- V. Botanic Garden (145 acres) and Mountain Garden (77 acres and 700 acres of virgin forest) with Laboratory.
- VI. Office, Library and Photographic Laboratory.
- VII. Forest flora collections.
- VIII. Laboratory for the study of Deli Tobacco.*
- IX. Experimental station for coffee.†

The second division has special laboratory accommodation for 8 foreign visitors, the institution acting, since 1885, also as an international botanical station that has already been visited by a great number of foreign naturalists.

It is hardly necessary to point out that the name of "Botanic Garden," does not give a fair idea of what the "Buitenzorg Institution" actually is. What is now the 5th division, corresponds, in general lines, with what was "the Botanic Gardens" till 1876.

In Dutch the difficulty arising from a no longer appropriate name, is partially avoided by keeping for the whole institution the original name "s Lands Plantentuin" and giving the name "Botanische tuin"† to the Botanic Garden belonging to the 5th division.

The Buitenzorg institution is working now with a staff of 27 Europeans, and over 200 natives.

The immense extent and variety of the Java Gardens must at once strike the reader; but still more conspicuous is the scientific as well as the practical enterprise of the Dutch Government in the staff of 27 Europeans and 200 natives attached to the Buitenzorg institution. It is useless to compare this with the three Europeans and handful of coolies given to the Gardens in Ceylon; but we believe it may be compared (to the advantage of Java rather than India) with what the Government of India does for the opposite Continent in this department. Ceylon ought at least to have a scientific staff of half-a-dozen Europeans—Director and Assistants, Entomologist, Cryptogamist, Analyst, &c.

THE "DURIAN" AS A NEW PRODUCT.

Now that tea prices are low, exchange high, cacao attacked in some places by a fungus disease, and perhaps other adversities looming before us,—the question of "New Products" is again being freely mooted by planters, and among other resources, at such a time, the durian as a fruit-tree may well claim our attention.

Fruit culture in Ceylon as a profitable industry, as well as for local consumption, has been frequently discussed in the columns of the *Tropical Agriculturist*, but notwithstanding it is still looked upon only as a prospective venture. The obstacles that lie in the way of such an undertaking are not all imaginary, it is true. The prospects of a local market are not sufficiently encouraging, and the variety of really good fruits that have so

far been found suited to our climate and soil is somewhat limited. Orange and lemon cultivation has not made the strides that were predicted some years ago; neither have pineapples and plantains yet tempted cultivation on any considerable scale. The mangosteen and avocado-pear have not been entirely overlooked; but the durian so far is somewhat of a *rara avis* with us. Observant visitors to our shores are quick to observe that if we are *fruges consumere nati*, our choice of locally-grown table fruit can hardly be said to redound to the credit of the planters whose reputation as the best agriculturists in the tropics has travelled so widely.

Although the durian (*Durio zibethinus*) may in one way or another be known to many of us, yet the opportunities of becoming acquainted with it in Ceylon are very few. This is much to be wondered at considering that in our comparatively near neighbourhood—the Malay Peninsula and islands—the tree is met with plentifully, both in its natural growth and in its cultivated state. Any one who has lived for any length of time in the countries mentioned must perforce be acquainted with the name of durian, and probably also with its flavour. There all the natives are born durian-eaters; even the dogs, cats, and tigers are said to be fond of it, and especially the civet cat, to entrap which it is often used as a bait: hence the specific name.

The durian fruit to the Malayan inhabitants has many wonderful attributes, however adversely its odour may be classified by people inclined to be delicate in the olfactory sense. Irrespective of drawbacks in this way—which in time may be considered trifling—the craving of the natives for the fruit is simply insatiable; and, when in season, many families, not content with the local supply, remove from their homes and fix their abode temporarily, in fact camping out, in areas where the durian is found to be plentiful. One of the chief attractions of the fruit to them is the aphrodisiac properties which they invariably believe it to possess. That it is in a measure exciting is scientifically admitted. Europeans also, notwithstanding the smell which is at first rather offensive, (being likened unto putrefying rats combined with rotten onions!) soon come to regard the fruit with peculiar favour, and when once they acquire the necessary taste, which is usually after the third or fourth trial, it is said to replace all other delicacies in the way of fruit. In fact, it has been said that the sensation of eating durians is in itself worth coming to the East for; and some writers on the subject describe it as being "beyond question the finest fruit in the world." It might be supposed too that it is also somewhat of a brantonic, for Governors of Ceylon—notably Sir Arthur Gordon, and others performing mental work of a responsible character—have declared that there is nothing to beat a good durian.

The Dutch ladies in Java are credited with having developed a considerable liking for it, and to be reported "eating durians" is often sufficient excuse for their non-appearance to visitors. A durian in general appearance is not unlike a small jak fruit, though of course differing widely in its natural affinities. The chief point of resemblance between the jak and durian is found in the peculiar angularly-marked rind surface common to both, and which in the latter forms a complete covering of stout spines or prickles. In both cases the fruit is borne on the older branches and trunk; but this is also characteristic of very many other tropical trees. In shape, a

* The divisions VIII and IX work at the expenses of private committees of persons interested in the culture of Deli tobacco and of coffee.

† The Dutch word "tuin" means gardens.

durian fruit is somewhat oval, and about the size of a large coconut. So the danger of walking under durian trees when laden with fruit can be readily appreciated. Fortunately, however, the fruits usually fall at night, seldom during the day. The edible portion is the cream-coloured fleshy pulp in which the seeds, which are about the size of nutmeg seeds, are embedded. The very mention of this pulp is enough to bring water to the mouth of durian epicures! The flavour is certainly all its own and apparently defies adequate description. A combination of cream-cheese, Sherry wine, and onion sauce, and other similar incongruities, seems to convey the most general conception of it. Various notions exist as to

WHEN THE FRUIT IS BEST FOR EATING.

Some say it should be left on the tree till ripe enough to drop or until it opens naturally (dehisce*). Very often, however, many of the fruits fall before reaching this stage either on account of their weight, wind, or heavy rain. But in many opinions this does not in the least detract from the quality of the fruit—provided the fall is not too early, of course—for it can be kept from a week to ten days to ripen.

For a novice to know whether a durian is fit for eating, it is only necessary to press the foot on it: if ripe, it opens at the growing end, showing five separate divisions. Those who are better accustomed to it, however, are guided more by the intensity of the odour which it emits, and of course, by the yellow tint the fruit assumes when ripe. Like almost all tropical fruits, the durian can also be used in the unripe state in a variety of ways as a vegetable: not even the seeds need be wasted, if not required for sowing. The conventional way of eating a durian is to retire to the bathroom or godown, with only nature's knife and fork (the fingers) to deal with it. But those who stand on scruples of etiquette may find the following recipe more to their taste:—

Extract the pulp from the fruit and leave it standing (in the back verandah) for a few hours, so that the offensive scent may escape; then place in a basin, and pour on it some fresh milk or cream; add a table spoonfull of sugar, or more if needed; beat well together to the consistency of thick cream; if the odour is still objectionable, add a few drops of rose-water; whisk the whole well, taking out any strands of fibre there may be, and serve the ambrosia. Unfortunately the durian does not readily recommend itself as a regular table fruit, for reasons already indicated. But the chief consideration for the present is

WILL DURIAN CULTIVATION IN CEYLON PAY?

The following facts justify a reply decidedly in the affirmative. Judging from what one sees in the markets of Colombo, Kandy, and Galle, the production of durian fruit in Ceylon is practically nil. In July and August, a few fruits are irregularly brought there and readily disposed of at prices varying from 50 cents to R2 each, Europeans often paying more than this when an opportunity of buying offers. Probably the largest and best fruits never find a place in the local markets, being sold to regular customers and given as presents to friends. A few trees on one favoured estate a few miles from Kandy supply all the fruit that reach the market of that town. More or less in consequence of this, many of the wealthier

Malays, we are told, leave Ceylon for their native country annually when the durian season there is approaching. From the prices mentioned, and the fact that even the ordinary Malay, Chetty, and Moorman—or for the matter of that all well-to-do inhabitants of the tropics, for the Sinhalese, Tamils, and Bengalees, have exhibited an indomitable desire for the fruit—is “fit” for anything between 50 and 200 durians in one season, it is evident that large quantities of the fruit could be profitably disposed of every year, in Ceylon. Unfortunately however the tree does not come into bearing until at least 14 or 15 years after planting. Nevertheless it warrants at any rate, a share of the patience that tropical planters are wont perforce to exercise, not unfrequently. It may therefore be placed on a par with the coco-palm; and the planter of durians in the island may feel assured his property will yearly increase in value. When in bearing each tree will mature from 50 to 300 fruits. Planted at 30 feet apart, an acre would contain about 50 trees, which at the low average of 100 per tree would give 5,000 fruits; these if sold at 50 cents each (now the minimum rate) would give the appreciable return of R2,500 per acre. This forms a contrast with the best record returns from tea or coffee, especially when it is understood that hardly any outlay is necessary on the cultivation of the durian tree, and that it can be grown from sea-level to 1,500 feet altitude in the humid Central and Southern districts of Ceylon. Of course, 50 cents per fruit is not a rate to base an orchard or estate estimate on; but put it at 10 cents each and where else can we look for a gross return of R500 per acre? We have

AN ADVANTAGE OVER OUR INDIAN NEIGHBOURS, for despite many meritorious trials at Calcutta, Madras, &c., they are not yet able to revel in their own durians. The variableness of that climate is quite unsuited to the plant, and even in the southern parts of India the durian can only be grown as a matter of curiosity. Consequently with the latest improvements in the system of cold storage, the development of an export trade in durians with India and other countries seems eminently feasible. The durian, though a fruit-tree, does not on that account lack in being

AN EXCEEDINGLY ORNAMENTAL AND GRACEFUL TREE.

It is the tallest fruit-tree in the world, reaching a height of 90 feet or more, is evergreen and always symmetrical in shape and well-proportioned in growth, so that it cannot readily be surpassed as an avenue tree. As a wind-belt and shade-tree for lowcountry estates, it would also no doubt prove a valuable acquisition, for the older trees afford good fuel, and the trunks being remarkably straight and of large girths would, if required, make excellent planks, etc. As to cultivation, the tree thrives in deep marly loam. It might be described as a deep feeder, there being no tendency to develop buttressed roots above ground, as might be expected from its size. When planting, unless the ground has been deeply tilled already, it is best to dig holes four or five feet deep by five feet wide, which should be filled in with such soil as mentioned above. Once the plants reach a height of nine or ten feet, which they do in three years in a favourable situation, practically no care is needed beyond keeping down undergrowths and protection from cattle, which are often fond of the young twigs and leaves. The fruits set independently of any

* Dehisce=to get open as the pods of plants.

artificial agency; that is, the flowers are *complete* (the two sexes in one). Plants can be raised by means of "cuttings," but propagation is best from seeds, which are remarkable for their power of quick germination, taking only about seven days to germinate. As a natural consequence, however, they soon lose their vitality, so they should be sown immediately on being taken from the pulp. In three or four months' time the seedlings are ready for transplanting to their permanent places.

VARIETIES :

Considering that the durian has been cultivated, though not on any systematic principle, for some centuries now, we cannot be surprised to find there are a few varieties, some being more prolific than others. It is difficult however to discriminate between them till they reach the fruiting stage. Closely allied to the durian is the "Katuboda" (*Cullenia excelsa*) of the Sinhalese known also as the "wild durian." This tree is fairly common in Ceylon, at low and medium altitudes in moist districts. The fruit is not eatable, but monkeys are very fond of it. It resembles durian proper in foliage and structure of fruit, and in fact the two are sometimes confused by botanists unacquainted with living specimens. The "Katuboda" however can easily be distinguished by the leaves being narrower, the fruit much smaller and covered with thickly placed, long, slender, recurved spines, and of course by the absence of a pronounced odour. [The "Katuboda" fruit is variable in the character of prickles: a specimen just under examination shews these to be rather closely set and sinuated, not regularly recurved.]

THE CULTIVATION OF INDIA-RUBBER IN NICARAGUA.

There has been a revival of interest in Nicaragua in the future of the India-rubber industry there, due to the decreasing yield and the resulting fear that the methods practised by the gatherers hitherto will lead to the extinction of the trees. The government has manifested its interest by means of the decree, published lately in *The India Rubber World*, prohibiting the exportation of other than cultivated rubber for the next ten years. This decree was preceded by laws for the encouragement of rubber-planting, and something has been done in this direction. But how far any law can prevent the exportation of native rubber remains to be seen. The United States consul at San Juan del Norte reported recently that, "notwithstanding the law made in Costa Rica some years ago prohibiting the cutting of rubber, much of the rubber shipped from San Juan del Norte comes from Costa Rica. It is estimated that Costa Rica has contributed between 35 and 60 per cent. of all the rubber shipped from San Juan del Norte."

Recently many persons in western Nicaragua—the Pacific-coast section—have declared their intention to plant and cultivate India-rubber in the eastern portion of the republic, investing some of the money which they have accumulated during several years past from their profitable coffee estates. Likewise many requests for information have been received in Nicaragua from citizens of the United States, bearing upon the whole subject of rubber cultivation, the impression evidently existing in many minds that India-rubber is becoming a scarce commodity. These circumstances have led to the preparation of some reports of interest published recently by the department of state, at Washington—one by Thomas O'Hara, the efficient consul at San Juan del Norte, and one by J. Crawfords, of Managua, the author of a paper, included in the volume of

special consular reports prepared at the instigation of *The India Rubber World* in 1890, which forms the most valuable contribution to our knowledge of Nicaragua rubber.

Consul O'Hara first calls attention to an extract from the Bluefields, *Recorder*, of June, 6, 1896, as follows:—

"On this subject of agriculture, we may add that a great deal of attention is being given to the cultivation of the India-rubber tree. Several of our banana growers on the river, while cultivating the product of the more rapid growth (the banana), devote some of their time to the India-rubber tree, which has the advantage of being a product full of staying qualities, yielding handsome profits after it has attained its full development, and which has not that baneful influence on the soil which is the peculiarity of the banana. We do not believe that we are beyond the mark when we say that there are to be found on several plantations on the Escondido more than 75,000 rubber plants, vigorous and promising, ready for transplantation. Ten or twelve years after these shall have been planted, bananas will be nowhere; the very places where they are now grown will be exhausted and allowed to lie fallow for the subsequent cultivation of other and less ephemeral products."

The consul has undertaken an inquiry respecting the details of such plantations, and he reports having learned through Vice-Consul Henry E. Low, at Managua, of two rubber plantations in western Nicaragua, with a producing capacity not to exceed 5,000 pounds a year. Further information on this head is promised to the department.

Mr. Crawfords writes in his report that localities in Nicaragua south of latitude 15° north and between longitudes 84° 10' and 85° 35', in low valleys where the soil is deep alluvial or deep vegetable humus and sand and capable of being rapidly drained and in a climate that is almost uniformly warm and humid, are best suited to the rubber tree. Many such valleys in central and north eastern Nicaragua supported groves of large-sized trees yielding rubber until about fifteen years ago, when nearly all the trees had been killed by too frequent tapping, or by being cut down by irresponsible collectors. There are, by the way, several species of rubber trees in Nicaragua, some of which are indigenous to a higher, drier climate and soil. Mr. Crawfords uses the term "elastic rubber" throughout his report, because some varieties, as the "tuno," for instance, are but slightly elastic.

Next to the *Castilloa elastica*, the second best rubber producers, in quality and quantity, are of the *Ficus* family, a variety locally known as 'matapala,' an epiphyte having numerous bodies from aerial roots (like the banyan tree). It is also an inhabitant of low, fertile, well-drained lands. By cultivation, this tree would, most probably, fully equal the other low-valley varieties in quality and annual output of rubber. It has the advantage that if one of its trunks or bodies is deadened by excessive bleeding or drainage of the sap, it has several other live trunks from which to obtain supplies of rubber." Evidently the tree thus described by Mr. Crawfords is not unlike the rubber tree of Assam and Burma.

"The quantity of the annual yield of elastic material depends," says Mr. Crawfords, "the soil and climate being suitable, on the bulk of the bast or lactiferous tissues that exist or that can be developed in the tree or vine. Some trees of two to three feet diameter and thirty-five to fifty feet tall will give annually twenty to forty pounds of good rubber. The quality of the rubber depends largely upon the shape or form of the cells and spaces composing the bast, or lactiferous tissue, and in part in the process used to separate the elastic material from the emulsion-like sap. Quality and quantity, therefore, are responsive to cultivation—to be increased or decreased."

Cultivation begins with sowing the seeds in beds and transplanting to a nursery at the end of the first year, and to the permanent plantation at two

and a half or three years. The planting is at such distances apart as to allow sixty-four "matapala" or 100 *Castilloa* trees to the acre. "Cultivation consists in ditching the land so as to drain it slowly or rapidly at will, keeping it moist without permitting water to stand in pools or low places. During the rainy season, drain rapidly. Keep all undergrowth cut down and the land 'hilled up' around the trees in cone shape to about six inches higher than the general level within five feet of each tree. Deaden or fell other varieties of trees and vines until they shade but a very small part of the surface of the land."

Tapping may begin during the sixth or seventh year of the tree's age. If the tree has matured properly it should yield from eight to twelve pounds of rubber every second year until it is twelve years old, after which ten to fifteen pounds of rubber should be obtained annually. "The coagulation of the milk and the separation from it of the elastic material can be effected by heating to 167° to 175° F. and stirring in a hot decoction or hot, strong tea of the leaves and twigs from some species of *Convolvulaceæ*—as morning glory or bindweed, or, stirring into the emulsion, when fresh and hot, the smoke from burning palm-nuts or other oleaginous nuts—all of which are abundant in districts where the rubber trees grow."

Secondary crops which may be grown profitably between the rows of rubber trees until they reach a productive age are Liberian coffee and bananas, the latter of which would afford a large percentage of the food required by all the animals on the estate.

As for profits, Mr. Crawfords estimates that sixty-four trees to an acre, at nine years of age and thereafter, should yield an average of ten pounds of rubber, or 640 pounds to the acre. At 30 cents net per pound, this would yield \$192 per acre, which should give considerable profit, the cost of cultivation being so slight. The net profit from an acre of coffee trees in Nicaragua is given at \$65.

Consul O'Hara's attempt to compile statistics of the production of India-rubber in Nicaragua has not been entirely successful. For example, the customs recorded at San Juan del Norte extend back only to 1874, and the invoices on file since that date do not, for most of the years, specify the quantities of India-rubber shipped, but only the values. He is now trying to collect the figures for the other ports, but even if these can be obtained, it will be impossible to say how much of the total represented the product of neighbouring states.

The India Rubber World happens to have at hand the details of Central American rubber imported by Great Britain and the United States for the years 1870 to 1885, inclusive, the greater part of which was the product of Nicaragua. The larger share was taken by Great Britain, until 1878, when the United States took the lead in the importation of Nicaragua rubber, which it has since maintained.

	Pounds.
Taken by Great Britain ..	6,654,780
Taken by the United States ..	13,789,499

Total for sixteen years .. 20,444,279

This without doubt practically embraces the whole production of Central American rubber for the years named, though a small amount may have gone direct to Germany. More than half this rubber was exported during the last four years (1882-85), and by far the greater part of this half was taken by the United States.

Nicaragua rubber then began to be entered separately in the United States customs returns, and the imports from that country alone have since been as follows, by fiscal years ending June 30:—

YEAR.	Pounds.
In 1885-86	1,552,574
In 1886-87	1,575,837
In 1887-88	1,545,121
In 1888-89	1,573,331
In 1889-90	1,209,730

YEAR.	Pounds.
In 1890-91	1,146,727
In 1891-92	1,027,232
In 1892-93	958,703
In 1893-94	892,908
In 1894-95	907,243

Meanwhile Great Britain has begun to record imports from Nicaragua separately, with this result, for calendar years: In 1892—7952 pounds; in 1893—37,072 pounds; in 1894—75,936 pounds; in 1895—33,264 pounds. There have also been unimportant shipments from Nicaragua to France, Germany, and Holland.

Just what has been the rate of decline in the output of Nicaragua rubber can only be conjectured, but that it has been great is proved by the following table showing the receipts of all Central American rubbers by the two great importing countries:—

	United States [a]	Great Britain [b]	Total Pounds.
In 1885 ..	2,079,278	237,552	2,316,830
In 1895 ..	1,300,802	33,264	1,334,066
Decrease ..	778,476	204,288	982,764

[a, fiscal year; b, calendar year.]

Nicaragua has not so long been a produce of India-rubber as many other countries. Its output suddenly more than doubled about 1880, continued at the figure then reached for a few years, and then began to decline at a rate which justifies the fears of the trade and the government that without protective measures the rubber tree will soon disappear from Nicaragua.—*The India Rubber World*.

INDIA RUBBER IN ASSAM.

A brief account of how rubber trees (*Ficus elastica*) are grown in Assam. By Mr. D. P. Copeland, Deputy Conservator of Forests, Darrang Division.

1. *Ficus elastica*.—The Indian rubber fig or caoutchouc tree, is indigenous to Assam, where it is found a dominant tree in the evergreen forests. It requires an exceedingly damp atmosphere, and the best natural rubber trees are met with in the forests at the foot of the hills, or on the hills themselves up to an elevation of 2,500 feet.

2. *Natural germination*.—In its natural state the rubber tree starts from seed dropped by birds in the forks of other trees, often 20 or 30 feet or even more from the ground, where it germinates, and the young plant remains an epiphyte for years until its aerial roots touch the ground; as soon as this takes place the little epiphyte changes rapidly into a vigorous tree, throwing out numerous aerial roots which gradually envelope the tree on which it first began life and often kills it out.

Having started life so high up it soon throws out branches which overtop the surrounding trees, and the numerous aerial roots which fall from these and establish connection with the ground, in a few years enable it to dominate the forest growth around it.

3. *Seed*.—The seed of this tree is contained in a fig-shaped fruit about 75 seeds being found in one good sound fig. The fruit first begins to form on the trees in March and ripens from May onward to December. On some trees the whole crop ripens and falls off by June, but as a rule the rubber tree has fruit on it from April right up to December, the figs forming, ripening and falling off the whole of the rains.

After collection the figs have to be carefully dried and mixed with pounded charcoal, which preserves the seed for several months.

4. *Seed beds*.—In the Charduar rubber plantation nursery, for a seed bed 40' x 3½', two to three seers of pulverized rubber seed, 10 seers ash and 20 seers of vegetable loam or good soil, are well mixed in a half cask and spread evenly over the bed, and then lightly stamped down and watered. Such a bed should yield with good germination, 2,000 seedlings and should be sufficient for putting out 100 acres of rubber planted 70' x 35'. The beds must be

well raised and drained, the soil being prepared in the same way as for vegetable or flower seed. If sown in boxes these should be put under the leaves of a house; if in beds light removable shades must be put up to keep off the direct rays of the sun. The shades should be removed during rainy or cloudy weather and at night.

Light sandy loam is most suitable for seedbeds, if the soil is stiff, charcoal dust should be mixed with it to make porous and prevent caking. The beds or boxes must never be allowed to get dry.

5. *Sowing*.—This should be done exactly in the same way as for vegetable or flower seed which requires transplanting after germination. The figs are broken between the hands. As the seed is very minute the particles of the fruit are left with the seed and sown with it, no attempt being made to clean or separate the pulverized figs. In order to distribute these minute seeds evenly over the seed beds or boxes, a certain quantity of ash and soil is mixed with them.

6. *Germination*.—Germination takes place from the end of April to the end of rains. Seed sown between October and January requires daily watering and screening from the sun, and will not germinate before the end of April or the beginning of May but seed sown any time during the rains will germinate in a few days (from five days to a fortnight). It follows the best time for sowing seed is during the rains that is from June to September.

The embryo appears on the germination of the seed as a seedling having a pair of opposite cotyledons with an entire margin destitute of incisions or appendage of any kind, with the exception of the notched or emarginate apex, oval in general outline, green in colour and of a glassy smoothness. The second pair of leaves shew a tendency to the alternate arrangement on the stem but appear at the same time. Their shape and venation are very different from those of the primary leaves for they have a central midrib and a distinctly coarsely crenate margin. The third pair of leaves do not appear simultaneously, and are distinctly alternate with a marked reddish colour. After this the plant is easily recognized.

7. *Pricking out*.—When the seedlings are two inches high in the seedbeds or boxes they should be transplanted into nursery beds, and put out in lines about a foot from each other. The nursery beds should be well raised and drained but the soil need not be so carefully prepared as for the seed beds. Here the plants are kept till the following rains when they are dug up and taken to stockaded nurseries in the forests and put out 5' x 5' on raised well drained beds; where they remain for two years till they are required for planting operations.

8. *Forest Nurseries*.—Almost every animal will eat the young rubber plants, it is therefore impossible to plant out small seedlings in the forest owing to the destruction by wild elephants and game, unless each individual plant is carefully fenced in. As this is too costly and the rubber after it is 1-2 feet in height is very hardy and can be transplanted with ordinary care, at any time of the year (the best time in Assam is between May and July), the seedlings are kept in stockaded nurseries in the forest where planting operations are to take place, and remain there till they are 10 or 12 feet high, that is about three years after germination, when they are dug out and the roots are cut back 18 inches right around the plant and planted on the mounds in the forests.

9. *Planting operations*.—In artificial planting it is found that the rubber grows best on mounds. Lines are cut through the forest 20 feet wide and 70 feet apart from centre to centre; in these lines 15 foot stakes are put up 35 feet apart. Round each stake a mound is thrown up 4 feet high. The base of the mound is about 10 feet in diameter and tapers to 4 feet on the top; on this mound the rubber tree is planted, care being taken that the roots are carefully spread out before they are covered up

with earth. To prevent animals pulling the plant and wind blowing them down they are tied to the stakes.

10. *Cutting*.—The rubber tree can readily be propagated from cuttings, it only perfectly ripe young branches or shoots are used, but the tree raised from cuttings does not appear to throw out aerial roots, and as the future yield of the tree probably depends on its aerial root system it is questionable whether trees raised from cuttings ought to be used except where required only as shade givers, such as in an avenue. In the Chardaar rubber plantation propagation by cuttings were given up very early, that is about 1876, the plantation having been commenced in 1879. The best time to take cuttings is May and June.

11. *General*.—The rubber grows equally well on high land or low land, in forest land or grass land, so long as it is planted on a mound and its roots are not exposed to the sun. It is a surface feeder, but as soon as its roots appear above ground they must be covered with fresh earth until such time as the tree has formed sufficient leaf canopy to protect itself.—*The Indian Forester*.

THE EXTRACTION OF GUTTA-PERCHA FROM THE LEAVES OF THE ISONANDRA GUTTA-PERCHA TREE.

Mr. Bourdillon has sent as a copy of an interesting report on the above subject by Professor W. Ramsay, Ph.D., F.R.S., of University College, London, from which we make the extracts given below. Could not a somewhat similar process be applied for extracting India rubber from the leaves of *Ficus elastica*? Perhaps some of our readers who are in charge of rubber forests would make experiments in this direction and let us know the results.

"The existence of a gum of a plastic nature in certain of the trees found in the Malayan Archipelago was first indicated by Montgomery, in 1832; but it was not until 1847 that Mr. Thomas Lobb sent specimens to Sir William Hooker. The material extracted from this tree was named "Gutta-percha" or the "Rag Gum," to translate the word literally. The word "rag" refers to the appearance of the gum before it has been kneaded into the usual compact form in which it is known in commerce. In 1848 the material was patented as an insulator for telegraphic wires by Messrs. W. H. Barlow and T. Forster, and in the following year by Dr. Siemens; so that its value for the purpose for which it is now in ever-increasing demand was early recognised. In 1849 Mr. Walker Brett laid the first cable, two miles in length, in the English Channel. It consisted of wire, insulated with Gutta-percha; and at the present date, with the exception of a small consumption for bottles and stop-cocks to resist the action of strong acids almost all the Gutta-percha produced is used to cover the wires of submarine cables. But the supply is far behind the demand. There is in existence to-day no less than 162,000 nautical miles of cable, and in 1884 over 3,000 tons were exported to England, involving the destruction of 12,000,000 trees of thirty years old. Owing to this great destruction of trees, the quantity of Gutta-percha in the market has been greatly diminished, and the price has risen accordingly, while the material is no longer of such good quality as it used to be. Indeed, it is stated ("Le Caoutchouc et le Gatta-percha," by E. Chapel, Paris, 1892) that the Chinese merchants are so much in the habit of adulterating the pure gum with resins from other species of trees, that it is not possible to find a pure specimen of Gutta in the market. The gums from species of Euphorbia are frequently used for this fraudulent purpose."

"There is great need to increase the supply of genuine Gutta-percha; and there is every prospect that a rich reward would recompense a successful effort to do so."

"The present process of producing Gutta-percha is, as has already been indicated, wasteful in the extreme, and very costly. The trees are either ringed, so as to cause a flow of sap, or felled, and in either case the tree is destroyed. Moreover the gum is mixed with impurities of vegetable matter, such as pieces of bark, and even with mineral matter, like sand and earth; to say nothing of the adulterations fraudulently added by the Chinese merchants. This necessitates a costly purification, which is achieved by softening and kneading the gum, or by squeezing it through wire gauze or some similar process, the results of which are, at the best, not very satisfactory. Solution in bisulphide of carbon, or in benzine, has also been tried as a means of removing these impurities, but the quality is thereby deteriorated. After the impurities have been mechanically removed, the gum is rolled between grooved or spiral rollers to expel water and air."

"The yield from a single tree, too, is by no means great. A tree of fifteen to twenty years old gives only three to three and three-quarter ozs. of Gutta, one of thirty years old gives some nine ozs., according to Serullas; and Burck gives about ten ozs. as the yield of a dichopsis tree twenty-six years old."

"The juice as it flows from the tree is white, on standing, it solidifies spontaneously, forming a sort of pellicle on the surface. On boiling or heating the juice, the Gutta collects into a more or less coherent lump."

"The Gutta as it comes into the market has usually a brown colour, which, however, does not belong to the pure gum, but is due to a trace of colouring derived from the bark; in some specimens the colour is dirty-white or pinkish, but the pure gum is really colourless. After being kept in the air for some time, the gum changes spontaneously to a brittle resin; this change does not occur if light be excluded, nor is the gum changed by light if air be excluded. Under water it is quite stable, whether the water be fresh or salt. It is found, too, that specimens differ in their power of withstanding the action of the air, and it is believed that the purer the Gutta the better it will resist the action of the air. It is found, indeed, that pure Gutta is only slightly attacked even after a very long exposure to light and air."

"In what is usually termed "Gutta percha" three distinct chemical substances are to be found. On boiling the gum with absolute alcohol a quantity of resinous matter is dissolved, varying with the specimen of Gutta employed. Even the purest gum in the market yields some 18 to 20 per cent. of its weight to boiling alcohol; and only what is left can be considered to be the chemically pure compound. Of worse varieties of gum, 40 or even 50 per cent. may be thus dissolved. These dissolved resins, although possessed of good insulating properties, cause the Gutta to deteriorate very rapidly if they are present in large amount; it becomes friable and easily disintegrated owing to oxidation. It is their presence in poor qualities of Gutta which renders them unsuitable for telegraphic purposes. But up to 18 or 20 per cent, they do not appear to act injuriously. The resins are named "albane" and "fluavile" respectively; the former, when quite pure, forms white crystals, the latter is a yellow gum. Both appear to be products of oxidation of the pure Gutta, albane containing twice as much oxygen as fluavile. Oudemans gives the formula of albane as $C_{20}H_{22}O_2$, and that of fluavile as $C_{20}H_{22}O$. But the chemical nature of these bodies, including Gutta-percha, has hardly been explored."

"M. Serullas has been led to devise a method of extracting these mixed gums from the leaves, instead of from the trunk of the Isonandra Gutta-percha. This tree used formerly to flourish in the Malay Peninsula in the neighbourhood of Singapore, but until it was re-discovered in 1837 by M. Serullas, it had not been utilised as a source of Gutta for thirty years, and it was supposed to have become extinct. It is the product of this tree which M.

Serullas says is best adapted for telegraphic purposes, for it yields gums containing the highest percentage of pure Gutta, mixed with the smallest proportion of albane and fluavile."

"In the best Gutta, the following are the proportions of these constituents:—

Pure Gutta-percha..	.. 75 to 82 per cent
Albane 19 " 14 "
Fluavile 6 " 4 "

"The process of extracting Gutta-percha from the leaves is an exceedingly advantageous one. To quote from the *Sarawak Gazette*, of the month of April, 1895:—"A tree of twenty-five to thirty years old yields one catty (one and one-third lb.) of pure dry Gutta, the same amount can be obtained by two pluckings of the leaves." The *Gazette* goes on to say that the stumps of trees which have previously been felled have now become covered with shoots, bearing rich crops of leaves; and that M. Hourant has induced the natives to collect these leaves, and that they are now exported in considerable quantity."

"M. Serullas states that a tree thirty years old yields 25 to 30 kilograms (55 to 66 lb.) of green leaves, or about 11 kilograms of dried leaves (24 lb.), from which it is possible to extract, by methods to be described, no less than 1,000 to 1,100 grams (over 2 lb.) of Gutta-percha, while the felled tree yields only 365 grams as a maximum. It would thus require that a tree should yield only 7 kilograms of fresh leaves per annum in order to give as large a supply as the whole tree felled, and with much less expenditure of labour."

"It now remains to describe the method of extracting the Gutta-percha from the leaves. The process is due to M. Serullas.

"The leaves, either fresh or dry, contain Gutta-percha. The process of drying, whether artificial or natural makes no difference to the percentage of Gutta, if the latter be reckoned on the dry leaves. The leaves, after being dried, are ground to a fine powder, and then mixed with one-tenth of their weight of caustic soda dissolved in water, and heated to boiling, or indeed digested under a slightly increased pressure. The liquor turns dark brown in colour, owing to the solution of a brown colouring matter, to which the Gutta-percha which usually comes into commerce owes its colour. The weight of the leaves, and also their bulk, is materially decreased by this process. The power is then dried by heating to 212°F.; a solvent is added, in a closed vessel, so as to hinder loss by evaporation. The mixture is heated so as to effect the solution of the Gutta-percha more quickly. The mixture is placed in a filter press, and the solvent is separated as completely as possible. The residue of leaves is washed with fresh solvent so as to extract the whole of the Gutta. The solution is of a greenish-brown colour, owing to the solvent dissolving out some chlorophyll—the colouring matter of leaves. As some solvent remains adhering to the powdered leaves, a current of steam is driven through this residue, which carries off the solvent and permits of its recovery. The extract is next placed in a still, and the solvent is partly removed by distillation, the pressure being somewhat reduced, so as to cause its boil at a temperature lower than that of boiling water. The concentrated extract is then run into a tank and mixed with twice its bulk of a volatile liquid. On mixing this liquid, which is done in a closed tank, there is produced a flaky or "raggy" precipitate of Gutta-percha. This precipitate is filtered off again by means of a filter press and the mixed liquids are run into a retort where they are submitted to distillation and are thus separated.

"The cakes of Gutta-percha from the filter-press are dried at a low temperature; they are then heated so as to soften them, and in presence of water they are moulded into lumps."

"The process is thus seen to be a very simple one. The products are easily prepared, and there is no loss except the unavoidable one, which always occurs when any substance is put through a round, and which is unlikely to be considerable."

"The next question is as regards the yield of Gutta-percha from the leaves and twigs. The following table is extracted from the valuable work on "Caoutchouc and Gutta-percha," by Seelgmann, Lamy, Torrilhon, and Falconnet, published by Britach, of Paris, 1896:—

	10	per cent
"Old dry wood	9.15	"
"Dry twigs	10.20	"
"	10.50	"
"Dry leaves	10.02	"
" imperfectly dried	9.06	"
" imported in water	10.05	"
" "	9.00	"

"I have myself extracted Gutta from the leaves of the tree, by the process of Serullas, some six or seven times. Even on a small scale, where the difficulties of extraction, filtration, &c., are much more considerable than on a larger, I have obtained a theoretical yield. The following is a typical analysis of a sample of leaves, chosen at random from among many:—"

Water in the naturally dried leaves	19.92	per cent.
Extractive matter removed by caustic soda	55.00	"
Gutta, reckoned on the thoroughly dried leaves	9.61	"

"The statements made by M. Serullas are therefore thoroughly borne out."

The following letter from the Director, Gardens and Forest Department, Straits Settlement, to the Director, Royal Gardens, Kew, which is printed in the Kew Bulletin for May and June 1897, gives a somewhat different account of the process. "I have just been to inspect the little factory where Mr. Arnaud makes his gutta-percha. Serullas has gone back to Paris with endless patents of different kinds, and Mr. Arnaud alone keeps up the business. The leaves are imported in sacks dry, from Borneo and Johore. Most of the trees are overcut in Singapore, and there are no more leaves left, I hear. The leaves and twigs cost four dollars and half a picul (133 lb). They are then put, damped with hot water, into a rolling machine, two rollers working against each other, which grind them to powder. The powder is thrown into tanks of water and shaken about. The gutta floats in the form of a green mealy-looking stuff, is lifted out by fine copper gauze nets, put in warm water and pressed into moulds. I have samples of the gutta as it comes from the leaves, and the pressed out finished article. It is really a very curious little manufactory. I do not know how long it will last, on account of the difficulty of procuring leaves, which must, I think, sooner or latter stop the trade.—*The Indian Forester.*

PRACTICAL EXPERIENCE IN LEGUMINOUS MANURING.

Dear Sir,—In P.O. of 15th August you published some experiments of mine in Leguminous manuring; and as "Wynaad Bean" in P.O., 9th January, asks that those who have tried the "Legume cult" should publish their experiences, I give you a few notes of what mine have been since August.

In my former letter I made mention of a 12-acre field manured in August and September 1895. The crop was small and I now consider the manuring was done too late, but at present time the tress are looking well and with a good spike. In June—July last year I applied "E. Lithosperma" cuttings to some other portions, and in three months the effect of the manuring was most marked, the trees having made a fine growth. They are continuing to look well and have an abundance of healthy spike. In October I manured another portion and the trees now show the effect of the manure by a nice growth of wood and leaves. The wood will of course not ripen to bear crop, and my experiments show the best time for applying Leguminous manure is not later than July. Their action is so quick that by applying them you get a wood for next year and help your tree through leaf disease.

I last year also manured with both Fish and Cattle manure, and before comparing results I might mention the cost to me of each manure. To cut and apply a good armful of "E. Lithosperma" cost 2 pies per tree. Fish applied at about 1 ton per acre cost 6 pies per tree. Cattle manure two baskets to a tree cost 1 anna per tree. Perhaps I did not manure my cattle manure as cheaply as it should have been done, and in calculating the cost I have taken cattle-keeper's pay and cost of applying. The fish was applied in May and the result is much the same as the "E. Lithosperma" manuring. The cattle manure was applied in June and so far the trees show very little appearance of having been manured and the benefit will come next year. The great point in "E. Lithosperma" manuring is its quick effect which proves that all the plant food constituents are in a soluble form and can immediately be taken hold of by the coffee. Those who don't know "E. Lithosperma" would be astonished at its quick growth, and when once established the amount of cutting it will stand. Albizzias are not in it with "E. Lithosperma" for growth. The wood is extremely soft, almost pithy, and if instead of the loppings being buried they are left on the ground, they decay and are eaten up by whiteants in a few months, thus improving the soil and feeding the whiteants. While on this point, I believe a remedy for whiteants in tea would be to place a quick-growing Leguminous tree, keep it lopped so that its shade should not interfere with the tea flushing. The loppings would feed the whiteants and they would not then trouble about the tea and the nodules on the Leguminous tree would be supplying nitrogen to the tea. Whiteants don't attack tea in a new clearing, at least this is my experience, but only in clearings which have been opened some years and where the tree roots and trunks have all disappeared. The whiteants having nothing to eat, they attack the growing tea.

If confirmation is wanted that planters are on the right attack in using Leguminous manures, I think what native cultivators do is a proof in that direction. In the paddy districts below these hills the price for a bandy load of such Leguminous plants as "Tephrosea purpurea" (Cassia Auriculata) is Rs. 2 and they are carted miles. For cattle dung the price is 4 annas, but this is never carted except from the house to the field. The native has also found out that Leguminous manures are quick acting and prefers to apply them to this three months' paddy crop rather than to the six months' one.

—Planting Opinion.

LEGUME.

THE COCOA EPIDEMIC.

I've read it in the pipers,
I've met it in the street,
It's all abahit the bloomin' 'bus
From wheel ter gawding-seat;
The sa'mple tin comes rattlin' in
Your letter-box all dye,
Free—or they'll pye yer fur it, if
Yer'll tike a tin awye.

Pickshur? Chap drinkin' cocoa.
Reading? It's always there—
It's cocoa this an' cocoa that
An' cocoa ev'rywhere;
It spiles the show where'er yer go,
It's 'ummin' in her 'ead,
Yer 'ole life smells of chorklit, and
Yer wishes yer was dead.

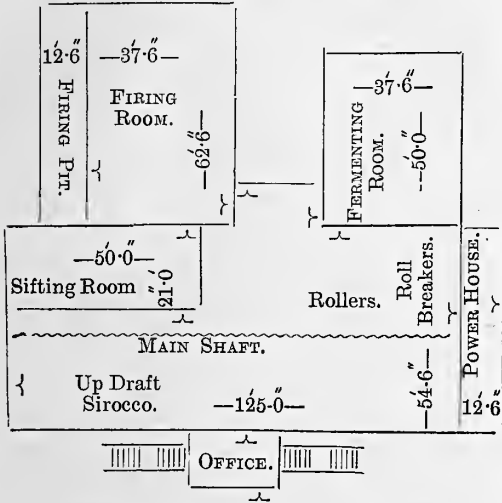

It's 'ighly chawged with phosphts—
I do not sye it's not;
It's grite on tonic properties,
An' touches of the spot.
It is (whichever mike it is)
The purest and the best,
Bnt cawnt yer sell us sumfink else
And give that stuff a rest?

—Daily Chronicle, Dec. 4.

A VISIT TO UDAPUSSELLAWA.
THE NEW FACTORY ON RAGALLA
ESTATE.

(By a Special Visitor.)

The Ragalla New Factory, or rather the work of levelling, was commenced on November 13th of last year, and tea-making was started in the building on the 10th June of this year and continued ever since. The plan of the Factory may be sketched for the printer as follows:—

GROUND PLAN. RAGALLA FACTORY.

THE GENERAL DIMENSIONS OF THE FACTORY are—main building, 125 feet by 42 feet, with a 12 feet 6 inch verandah running the full length of the front side. The manager's office is in the centre of this verandah, but built higher and with a storey above it, for weighing the green leaf and as an entrance to the second floor. This entrance is approached by "ladders" from both sides running parallel with the main building. Ordinary stairways have not been adopted: sloping platforms reaching up to the entrance being considered more convenient. One of these "ladders" has ribs of wood to keep the coolies from slipping on wet days, but Mr. Nicol for the sake of the younger pluckers and to make the ascent as easy as possible for them has left the other without these ribs. Behind the main building almost at each end and built at right angles to it are the fermenting and firing rooms with an open court between them. The latter has an open verandah, on the outer side, from which the driers are fired, and is only one storey in height. The fermenting room however has two upper floors, same as the main building, for withering purposes. The fermenting room, unlike the rest of the factory, which has only three feet of brick above the ground level, has been built up with brick for 17 feet on both sides, and on the gable end with 14 feet. This is for the purpose of keeping the room as much as possible from being affected by the direct rays of the sun. The room itself is 50 feet by 37 feet 6 inches, and has a concrete floor. On passing into

THE FERMENTING ROOM

from other parts of the building we at once felt a considerable reduction in temperature, almost equal to the difference between the night and

day shade temperature of the locality. By a thermometer placed in the room, we found the temperature was about 64 degrees Fah. This lowering of the temperature is secured by hanging ordinary jute hessian from wires running the full length of the room, about 10 feet above the floor, and saturated with water. These jute hessian screens run down on both sides of the room, having immediately below a drain in the floor covered over with cast iron grating to carry away the surplus water falling from them. Besides these screens, and just in line with them, are two water taps, which are kept running as required to help to reduce the temperature. Practical tea planters will understand the reason for the moderation of the temperature while the fermenting operation is proceeding. The volatile and delicate

ESSENTIAL OILS OF TEA,

which, of course, give character to the commercial article readily evaporate from the newly rolled leaf. How to retain the essential properties of the leaf during the process of manufacture is the crux of tea-making, and perhaps the higher temperature at which low-country tea is gathered and manufactured may partly account for its inferior flavour! Who can say? We knew of one gentleman who was experimenting in this direction, by devising means to fire the tea in a vacuum! We have never heard with what result. This point, however, opens up the whole question of tea manufacture, and it is here where, perhaps, an expert chemist might score. In any case, the advantages of cool rolling and cooler fermenting is now widely recognized, although, perhaps, the practical application of the knowledge is not so widely effected owing, in many cases, to want of accommodation.

THE FIRING-ROOM

is 62 feet 6 inches by 37 feet 6 inches, and is fitted with an ample ventilator or lantern in the roof. The heated air can be directed into the withering-floor, by ducts which can be operated to supply either the one or the two floors to help the withering process. A new paragon drier fired, as already stated, from the verandah as well as a down draft sirocco, is installed in the firing-room. Both are driven from the main shaft by a counter shaft on to a short secondary shaft let through the wall on a level with the floor, which then drives the shaft in the firing-room. The paragon was in operation when we visited the factory, and on entering the room, the sweetest scented air we remember having ever experienced in a tea factory greeted our olfactory nerves, and, we could not help expressing our delight. It was more like going into a confectioner's shop with its delicate intermixture of scents! Here were the essential oils from the tea dissipating under the influence of the heat of the paragon, and which if retained might add a penny or twopence to the price of the tea on the market! This paragon is capable of making 400 lb. made Tea per day, and is a beautiful piece of machinery in every way.

THE SIFTING ROOM

is a part of the main room partitioned off, close to the Firing Room. All the rooms are partitioned from each other by half glass partitions and large door ways by which access can be got from the main building to any other one direct—verandah connection between the fermenting and firing rooms, 25 feet by 12, feet wide, facilitating access in their case

to each other. The size of the sifting-room is 50 feet by 42 feet. The machinery here is a Jackson's "Eureka" sifter, a Jackson's tea cutter and Davidson's tea packer. A 24-inch Blackman's fan is used in the sifting-room to expel the dust, not placed as is usually seen in the generality of sifting-rooms, near the top of the room, but level with the floor. This is its proper position, for the dust tends to fall, and the fan helps it.

THE LEAF-ROLLING ROOM—

the main room of the building is open and spacious, — feet by—feet. The first floor of the building is placed exceptionally high, so that the light of the whole ground floor is as good as could be desired—an important desideratum for facilitating careful manufacture and cleanliness. In this connection, a system of drains, covered with cast iron perforated covers, allows copious washing without any difficulty in getting rid of the water, etc. These drains run below all the rollers, roll breakers, and sifters. In the centre of this room the pillars, which support the second floor are placed sufficiently wide apart to obviate any appearance of crowding or breaking up of the space. There are nine pillars and these support the transverse beams all are 8 inches by 4 inches. Along these pillars run the main shafting for 138 feet varying in diameter from 4 to 2½ inches supported by angle iron brackets; and one useful apparent improvement on the usual arrangement for oiling purposes, is the erection immediately below, of a neatly constructed light staging extending from one end of the shafting to the other. This will be of much value in giving ready access to the bearings for any purpose.

THE MACHINERY

in this room is a Jackson's 32-inch circular "Rapid," a Jackson's square "Rapid," an "Economic," made by Walker, Sons & Co., 2 Michie's Roll Breakers, also made by Walker, Sons & Co., and one up-draft sirocco, for refiring purposes. All the machinery is new, except the square "Rapid" and Davidson's down-draft sirocco. There is provision made for the installation of 10 rollers altogether, and when these are placed it may be easily computed, what the output of this splendid factory will amount to. The rollers will be in two rows on each side of the main shaft and at the end nearest to the turbine, and close to the fermenting room. The sirocco is placed in the verandah, in line with the sifting room. It is sunk 6 feet below the factory floor, and very conveniently placed for refiring the manufactured teas. The whole arrangements of this room gives a feeling of great freedom, and is in every way arranged for the practical, expeditious, and easy handling of large quantities of tea leaf.

At the end of the factory nearest the turbine is an ordinary stair ladder reaching up to the second floor, with another from the second to the third floor at the entrance above the office. On ascending we found ourselves face to face with a thicket of wood shelving. This was the first time we came across the extensive utilization of

WOOD INSTEAD OF THE JUTE HESSIAN TATS generally in use. It is well-known that leaf gets a better wither up on wood than upon hessian, and full advantage has been taken of this fact in the Ragalla factory. On the second floor of the main building these tats are arranged to allow 2 feet 3 inches space as room to pass down the centre and on both sides,

so that easy access is gained to spread the leaf. Above the fermenting room, the tats are full breadth across, 33 feet, leaving room on each side only. The tats are made of pine deal, 3ths inch by 7 inch wide, put together to form a width of 3 feet 9 inches, with three inches of a slope. Six inches are left between each shelf, and these are piled up to the ceiling of the third floor, not too much out of reach from the floor. The usual arrangements hold for sending down leaf to the rollers. Each floor has a 48-inch Blackman's fan, so placed as to draw the heated air from the firing room right through both floors. In the whole factory there has been used about 90 tons of wood alone, and this will of itself give some idea of the proportions of this modern and up-to-date factory.

In closing our remarks about this splendidly arranged factory, we may state, that it was built and designed by Messrs. Walker Sons & Co. Ltd., the well-known engineers, &c., of Colombo and Kandy, and everything in connection with the factory reflect of them the highest credit, for the care and finish bestowed on every detail. Mr. Holland Porter, we believe, has been the representative of the firm more immediately concerned with the building since its inception, and it is highly satisfactory evidence of his executive ability and professional skill.

TEA IN DARJEELING.

Nov. 16.

Leaf is still struggling out, but the season is nearly closed. We are, however, all making more tea than is usual at this time of year, on account of the warmer nights. The tea is very flavoured and will sell well in the London market, but these cold-weather-flavoured teas do not seem to be appreciated in Calcutta. The weather has been stormy in the afternoons for the last few days, very black thundery-looking clouds getting up, but they come to nothing and disappear in the evening. We do not want any more rain until Christmas time.—Planter.

THE NEW MAP OF THE TEA ESTATES AND DISTRICTS.

AFTER many disappointments and heart-breaking delays, we are at length enabled to offer to the public of Ceylon—and especially to the planters and merchants—the long-talked of, map of the Tea Districts, as compiled under our direction, and lithographed at one of the first London establishments. We are very far from claiming "perfection" for our map—indeed we are conscious that there must be not a few errors, most of which are attributable to our having had no opportunity of verifying the "proofs" or supplying the latest corrections as we should have done, had we been near to the lithographers. Still we trust the map will be found a fairly accurate and useful production—at any rate a great improvement on its predecessor of 1875. The execution by the printers has been admirable, we think—the printing being very clear and attractive.

If a second edition should be called for, we may hope to make any specially needful emendations.

THE AGRICULTURAL SCHOOL: A PRIZE STUDENT FROM THE STRAITS.

MR. A. R. Jeremiah, who was awarded more than one prize and a certificate of merit at the late distribution of prizes at the School of Agriculture, came over from the Straits Settlements

with the special object of joining the School. He has gone through the full course of study extending over two years with credit; the only pity being that he could not have been shown the cultivation of the Ceylon products as carried on, on our estates, the Government making no provision for taking the Agricultural students on tour.

CACAO DISEASE AND SHADE.

Dec. 3.

PLANTING NOTES FROM MATALE WEST.

Pluckers will be very busy again. This season has been a good one for cardamoms, and with the high price we are having, owners of cardamom fields will have a happy time of it. I wish the same could be said for those having tea, cinnamon and coconuts.

Mr. Willis and the expert's opinion on the cacao disease are interesting reading, but the opinion that heavy shade might be one of the causes, does not seem to hold good, when one sees the growth of cacao on Marakona, where the shade is more dense, than any property I know of. Passing by train through about two or three miles of this property, one does not see for miles, a tree diseased, while higher up and lower down, a good many trees are diseased. A good number of planters passing this property were of opinion that the soil on the estate was too poor, as cacao required a rich deep soil, but luckily there was the superintendent, Mr. Holloway, who knew what he was about, and allowed weeds to grow, thus saving wash. Latterly when the estate had a fair amount of shade, the weeds were cut down, and mixed with lime and buried, thus giving the trees a good manuring at little cost, and making the soil richer than when first planted.

If this estate was kept clean from the commencement of planting, the soil exposed till the shade came on would have hardened, and with the rains, there would have been a great deal of wash.

CHOCOLATE CULTURE IN NICARAGUA AND MEXICO.

BY ROWLAND W. CARTER.

The visitor to Nicaragua, will not be long in the country before an opportunity to 'sample' Tiste will present itself. It is a preparation of powdered cacao beans, sugar, maize-flour, and water, and may be called the national beverage. Europeans, accustomed to the chocolate of the French and Italian cafes, do not at first care for it, but they soon recognise its virtues. To the poor peon it is often both food and drink, and with a jicara gourd more or less full of it on his back, he will toil contentedly for six or eight hours, asking no other nourishment.

Long before the conquest, a decoction of which the cacao bean formed the principal ingredient was held in the highest favour in Mexico and Central America. The Aztecs called this drink *chocolatl*, and every tribe they subjugated had to bring a certain number of bags of cacao as tribute to the Emperor. The chocolate of those savage conquerors was flavoured with vanilla, even as ours is today, but other spices, some of which have not been identified, were used to improve this 'food for a god.'

EARTHQUAKES GALORE.

I am not likely to forget the catastrophe which led to my first introduction to *Theobroma Cacao* as cultivated on a large scale in Nicaragua, for it was nothing less than an earthquake. Seismic dis-

turbances are common in Central America; and the volcanoes on the flag of Nicaragua are not without meaning. It is a land of volcanoes, and the sonorous names which the Indians bestowed still cling to many of them, telling, as plainly as sounds can, of the awe and dread the ancient people held them in when they were not slumbering, as now, but active and malevolent. Omotepe—Mombacho—Momotombo—the names suggest a rumbling and roaring, fire, and a lava flood that nothing could withstand.

Granada, where I was dwelling in September 1890, stands at the foot of Mombacho. At one time it was the capital, but the jealousy of Leon has made Managua the seat of government. Granada, indeed, has never recovered from the Filibuster War, when General Henningsen almost razed it to the ground. Before the Revolution, and since, it was a city of palaces. Now it is more or less ruinous.

On Sunday, the second day of that eventful September, I was sitting in the patio, or court-yard, of the house in which I resided, when I suddenly became aware of a muffled roar, not unlike distant thunder, but apparently proceeding from the ground, which quivered under my chair. My companions instantly sprang to their feet.

'Tremblor—Tremblor!' they shouted, and ran through the wide portiere in to the street. I followed. They, and hundreds more, men, women, and children, were racing towards the plaza, or great square. Hysterical shrieks, cries, and shouts filled the air, which was so thick with dust that I could see no better than in a London fog. The plaza was no great distance, but the vibrating ground made my steps so uncertain that it seemed many minutes before I joined the terrified throng already gathered in that open, and therefore comparatively safe place of refuge. Some, struck down by falling tiles and bricks, never reached it, but the casualties were few.

The roar and the quivering died away, and after a while the people, thinking the danger at an end, began to return to their homes. But I had scarcely reached the patio that I had left so hurriedly when another shock, sharp and sudden, sent us all flying to the plaza again. This was followed at a brief interval by a third and a fourth, each more violent than the preceding one. Stone houses rocked to and fro like poplars in a hurricane; adobe walls cracked and fell; roofs seemed to be stripped off entire; but the huts of the poor, built of timber, with walls of plastered canes, generally escaped. The crash of falling masonry, clanging of bells in the church towers, howling of dogs, cries of children and lamentations of their parents, made an uproar almost indescribable.

A few priests of Spanish blood ran about endeavouring to calm the people; but many cried that it was the Day of Judgment, while others declared that it was heaven's punishment on the inhabitants for visiting the theatre, where an operatic company had been playing *La Mascota*.

The shocks continued at intervals for twenty-eight days—four weeks of panic, desolation, and distress. Those who had haciendas in the country fled thither, leaving their city houses at the mercy of thieves, whom even earthquakes could not restrain from pillage. The government ran free trains to places of safety, so that long before the shocks came to an end Granada was comparatively deserted. Those who remained ate and slept in the streets. I, almost a stranger in a strange land, did not at first know where to go until I bethought myself that I had an invitation from the manageress to visit the 'Valle Menier' cacao estate, situated near Nandaime, about half-way between Granada and Rivas. Thither I went, leaving my lares and penates in the care of the earthquakes, with small hope of seeing them again.

A LARGE CACAO PLANTATION.

The 'Valle Menier' plantation is by far the largest and best-managed in Nicaragua, and, as its name will indicate, it is the source of the famous 'Chocolate Menier,' so largely consumed in France and England. The owners, Messrs. Menier Brothers, of Paris, cultivate the cacao in a thoroughly

systematic way, and in consequence they have no rivals in Nicaragua, and no superiors anywhere—that is, as regards the quality of their product. The careless, unstudied methods of the native hacendados are scorned at 'Valle Menier,' where the very best machinery available is in use, and nothing spared in order to attain perfection.

Of course the earthquakes, of which Granada seemed to be the centre, were felt in the valley which the Brothers Menier have made so productive, and there was great excitement during my stay; still, I saw enough to convince me that a cacao plantation, carefully and systematically managed, is a very profitable investment. And this I think I shall be able to show.

Theobroma Cacao is a tree of moderate size, averaging when in a wild state from twenty to thirty feet in height. Its deep green oblong leaves vary in length from eight to twelve inches, and are generally about three inches broad. The light red or pale yellow flowers, growing in tufts at the extremity of the branches, are small. On these falling, the gourd or lemon-shaped pod appears. It is about eight inches long by three in diameter, and has a thick, tough rind, light green at first, then pale red, and eventually reddish purple. The pod contains from thirty to forty seeds, closely packed in white pulp. These seeds after being fermented, rubbed, and cured, constitute cocoa; if they are merely broken up, they are known as cocoa nibs. The soluble cocoa familiar to all is composed of the seeds or beans finely ground and mixed with starch. Chocolate is the same thing, but made up into a paste and flavoured.

There are many varieties of the cacao tree. The Tobasco cacao of the Atlantic slopes of Central America, and the famous Socunusco cacao of the Pacific shore are obtained from *Theobroma angustifolia*. This is supposed to be the best cacao known, and very little of it finds its way to foreign markets. In addition to Mexico, Central America, and many of the West India Islands, cacao of excellent quality is obtained from the United States of Colombia, Ecuador, Venezuela, Brazil, Ceylon, Madagascar, the Philippine Islands, &c. In British Honduras, *Theobroma Cacao* and *T. angustifolia*, the famous cacao tree of Socunusco, both grow wild. Mr. Morris, now the assistant-director of Kew Gardens, saw a number of them on the banks of the Rio Grande, 'with their stems covered with flowers, and often loaded with fruit,' growing 'under the shade of large overhanging trees in deep soil, and in rather moist situations.' British Honduras, therefore, where the most valuable species are indigenous, would appear to be the most favourable of our colonies for a cacao plantation.

PRACTICAL HINTS.

In choosing land an elevation of from three hundred to six hundred feet is desirable: the plantation must be sheltered from the winds and the direct influences of the sea-breezes. The cacao will thrive close to the sea-shore but the site must be sheltered. The well-drained but moist alluvial lands in the river-valleys afford the best soil and situation.

At the 'Valle Menier' in Nicaragua, when I received my first lesson in cacao cultivation, only seedlings, propagated in nurseries, are planted out. In other places the method known as planting 'at stake,' that is, propagating on the plantation, is sometimes adopted but this I cannot recommend. When the plantation is intended to be made on lands covered with virgin forest, the first step is clearing a space for the nursery. When the trees and undergrowth have been removed, the soil should be hoed and raked, and all weeds carefully pulled up. For planting, the best-looking pods, not over-ripe, should be chosen. Those known in Mexico as 'hechas' are generally preferred. They are light-coloured and solid, and distinguished from the 'viches' by the seeds not rattling inside. A light tap with a knife handle is the test usually employed.

The seeds should be planted eight inches apart and one inch deep in small furrows, covered with

loose, fine mould and banana leaves, and watered lightly every morning and evening for a fortnight, when the seedlings will begin to show above ground. The banana leaves should then be removed, and a roof of palm or other large leaves, raised on sticks, constructed to shield the young cacaos from the sun. This done, the planter may leave them and turn his attention to the land where they will be planted out.

The close of the rainy season is the proper time to begin clearing. This varies according to locality, but in the Rivas district the winter or rainy season—'Invierno,' as the natives call it—commences about the middle of May and ends in the middle of November. In Mexico the rainy season is not over, as a rule, before the end of December. The first step is to mark the valuable timber trees, fell them, and haul them away. The remainder, with the undergrowth, should be cut down, leaving, however, a belt on that side of the plantation which is most exposed to the wind. The branches should be lopped off the trunks, and the whole left a month to dry. When perfectly dry the brushwood and trees should be piled in convenient heaps and burned. It is advisable, however, to sort out such vegetation as will decompose quickly and allow it to rot for use as a fertiliser. When the whole is destroyed by fire, constituents very necessary to enrich the soil are given off and lost.

SHADE.

As the cacao trees require to be shaded from the direct rays of the sun and sheltered from violent winds, it is customary in Nicaragua to leave such trees standing as can be utilised for shade. When more shade is required, cuttings of fast-growing trees called 'Madres de Cacao'—mothers of the cacao—are planted to supply it. The tree generally used for this purpose in Nicaragua is locally known as 'Madera negra.' Various species are used in different places, but the most common perhaps is the Savonetia of Trinidad, supposed to be identical with the 'Madera negra.' As a rule these trees serve no other purpose than to give shade, whereas the banana, planted as a shade-tree, will yield fruit as well. I recommend either the banana or *Castilloa elastica*, the india-rubber tree, for this purpose, and give the preference to the latter, as being much more valuable and lasting. It would be a good plan to plant bananas first in rows fifteen feet apart, each tree in the row forty-five feet distant from the next. They spring up directly and afford good shade in six months or less. Then rubber and cacao trees should be planted between the bananas, thus forming a composite plantation. The bananas die down after fruiting, but are soon replaced from the same roots. When the rubber trees are big enough to shade the cacao, the banana roots might be grubbed up, leaving the rubber and cacao in possession of the ground. The space occupied by the bananas might then be filled up with rubber, or cacao, as desired, when the trees would be fifteen feet apart. As the *Castilloa elastica* is a deep feeder, and proof against the attacks of insects, it is perhaps the best possible shade-tree. The *Castilloas* may be tapped in the eighth year, when they will yield, on an average, five pounds of rubber worth two shillings a pound. The quantity of rubber will increase every year for a certain period, and continue for from twenty to thirty-five years or longer.

PLANTING OUT.

To return to the cacao seedlings. When twelve months old they will be about two feet high and ready for transplanting. This should be done at the beginning of the rainy season. Considerable care is necessary. In Mexico the process is as follows: A peon cuts a circle or square round the seedling with a machete, then with a spade lifts up both earth and plant. Another peon stands by with a large leaf, which he wraps round the mass to retain the earth and guard the taproot. Holes two feet square and two feet deep having been dug fifteen feet apart, or that distance from the shade-trees, the young cacaos are carefully placed therein, the holes filled up, and the earth well pressed down. Dried leaves, banana trash, or mixed wood ashes and decomposed vegetable

matter should be placed on the top, and the operation is complete.

At two years old the tree, in good soil, will stand five or six feet high: when seven or eight feet high it will begin to bear, and when ten or twelve feet high it will be in full bearing. This will take place in from the fourth to the seventh year, according to situation. In the meantime considerable attention is necessary. Twice in each year the land should be weeded, and the trees must be carefully pruned.

PRUNING.

With regard to pruning I quote from a valuable report on the productions of Mexico by Sir Henry Dering: 'As the pods are borne on the larger branches, the principle is to develop such branches and see that they are not covered up by foliage and small twigs. A typical cacao tree should have one stem, giving off at a few feet from the ground three to five branches, which spread in an open manner and are free from leaves except at the top; thus the leaves shade the open inner portion without interfering with a free circulation of the air. If the young plants throw out more than one main stem, the surplus ones must be pruned off when the moon is on the wane; and after the lateral branches are formed, no upward prolongation of the stem must be allowed to grow. If the tree be left unpruned, these upward growing branches will shoot from the stem just below the laterals in the form of suckers, and to leave them on is to cause the strength to be taken from the fruitful laterals, as well as to allow the trees to run up, perhaps for thirty feet or more, thereby causing much trouble in picking the pods. When the suckers are pruned off, fresh ones will grow in a short time, so that the trees will require frequent attention until they are mature, when the tendency to throw out suckers will be stopped.'

After the flowers have fallen a small pod appears like that of the Chile pepper, maturing in three or four months. The first flowers, however, should not be allowed to produce pods, but should be rubbed off. As the cacao tree blossoms all the year round, the harvest is practically unceasing, but for convenience there are considered to be four harvests, each covering three months. That lasting through April, May, and June is the most abundant. When the pod takes a reddish purple tint it is generally considered to be ripe, but this is definitely ascertained by tapping it with a stick or the knuckles. If it sounds hollow, and the beans are loose, it is gathered.

HARVESTING.

In the harvesting great care is necessary, or the next fruiting bud, which grows close to the pod, may be knocked off, and the branch rendered barren. When the pod is beyond reach the mozo generally uses a curved blade attached to a pole, and with a peculiar twist removes it without damaging the branch. When gathered, the pods are placed in heaps under the trees for twenty-four hours, then carried to the cacao-house and again heaped up. Round the heaps a number of men, women and children take their places. With their machetes the men open the pods, which are then passed to the women and children, who remove the beans.

CURING.

On large plantations, such as the Valle 'Menier,' the beans are then carried to the 'sweating-house,' heaped together, covered with banana or plantain-leaves, and allowed to ferment for from four to six days, according to the season and temperature. To insure thorough fermentation, the heaps are occasionally levelled and re-made. Unless this is done the beans in the centre of the heaps will turn black. When sufficiently fermented they are placed on shallow wooden trays and exposed to the sun to dry. Sometimes 'Barbecues,' or yards with a flooring of cement, are utilised. But whether dried in the trays or on a floor, the beans should be protected by a moveable roof of canvas running on rollers, or a temporary thatch of plantain or palm leaves. When the sun is out

the roof is rolled back and the beans are exposed: during rain at nights the roof is rolled over the trays or the yard as the case may be. This process is continued until the thin skin covering the beans becomes brittle and may be easily removed.

As the drying is very important, I quote again from Sir H. Dering's report:

'Where they are dried in yards the sweated beans are spread out thinly, well rubbed, and exposed to the sun in the morning, and at mid-day put back in the sweating-house to undergo another partial fermentation, for if they be dried straight off they will deteriorate in value. A peon must turn them over once in a while during the day, so as to expose the whole seed, otherwise one side only will become red and the other black. The second day they are kept longer in the sun, and the third day they remain out as long as the sun lasts. They are put out on succeeding days until they are thoroughly dry, which is told by their producing a crackling sensation when pressed between the thumb and forefinger, or when the outer skin breaks off easily. To brighten the colour to a deeper red, the beans are washed in a 33 per cent. solution of lemon or sour orange juice. Sometimes the cacao is clayed—that is, sprinkled with red clay that has been dried and pulverised—immediately after they have been removed from the "sweating-house."

Claying, however, is not advisable, as the buyer can tell immediately when the natural colour of the beans has been artificially heightened. Beans of a deep-red hue sell for the best price, but this should be attained by silklful curing, and not by giving them a coat of clay. The wash of lemon or orange juice is quite harmless. When perfectly dry the beans may be placed in sacks and sent to market.

CROPS, PRICES, AND PROFITS.

The yield of a mature cacao tree varies considerably; in Nicaragua it ranges from 3 to 8 lb., and I think 6 lb. per tree may be taken as a fair average. Sir Henry Dering, referring to Mexico, states:

'Generally one can reckon on 50 pods per tree a year, each of which will produce from 30 to 40 beans, and 250 dried beans will weigh one pound.' Taking the lowest number of beans per pod, namely, 30, this would give 6 lb. per tree. The trees, if carefully cultivated, will continue in bearing for from 22 to 25 years.

The price varies considerably. Cacao beans sometimes sell for 50 shillings per cwt., and at other times for as much as 130 shillings. Fair qualities may be said to average 75 shillings, but in estimating cost and profit I propose to base my calculations on the low average price of 65 shillings per cwt.

Sir Henry Dering estimates the cost of cultivation at £8, 8s. per acre, which includes the price of the land and all expenses incidental to forming a plantation. In order to be on the safe side, I estimate the cost at a shilling per tree to the end of the sixth year, so that an acre, planted with 193 trees, will have cost £9, 13s. The expenses of harvesting and curing Sir H. Dering places at 2½d. per lb., which is very fair. The following figures will show the cost and profit of one acre of land planted with cacao trees 15 feet apart:

	<i>Dr.</i>	<i>Cr.</i>
Cultivation, including cost of land, clearing &c., for the term of six years, at 1s. per tree.....	£9 13 0	
ng and ng for of 1153 cacao, at 1 lb.....	10 17 1	
Bla.....	13 1 11	
	£33 12 0	
		Yield of one acre, planted with 193 trees, bearing 6 lb., each, or 1158 lb., at 65s. per cwt...£33 12 0
		Profit, £13, 1s. 11d.

Each successive year, for twenty years or more the plantation would yield a crop of the same, or

greater value, whilst the only expenses beyond those of harvesting would be the cost of two annual weeding, pruning, and occasionally replacing a tree. These £5 per acre would more than cover. The profit, therefore, for the seventh and succeeding years would be £17, 14s. 11d., or 87 per cent. on the original capital expenditure of £20, 10s. 1d. per acre. The figures given by Sir Henry Dering show a cost per acre to the sixth year of £20, 13s., and a net annual profit of £53, but his calculations are based on 300 trees to the acre, which, in my opinion, is too many. Enough has been written, however, to show that chocolate growing is a very paying occupation.—From "Chamber's Journal," Oct. 23.

AGRI-HORTICULTURAL AND COTTAGE SHOWS.

Much credit is due to the Executive Committee and office-bearers connected with the late Agri-Horticultural Show at Nuwara Eliya—one of the most successful and useful in every way ever held in the island. The rock on which such Shows usually split is the financial one; but it will be seen by the accounts given elsewhere, how well matters have been managed this time, and how the Committee have been able to supplement with medals and votes where merit called for the same. The only omission we can observe in this part of the business has reference to Mr. Nock who, we suppose, more than any other individual, laboured for the success of the Show. We should have liked to see a gift or at least a special medal sent his way. The proposal to follow with a Cottage Show and to maintain such Shows once a year, is a most commendable one and has our hearty support. Still more important and suggestive is the further proposal included in our Special Telegram on Saturday, and reported more in detail elsewhere, and we sincerely trust that His Excellency the Governor may see his way to support the appeal for a PERMANENT ASSOCIATION to arrange for AGRI-HORTICULTURAL SHOWS at intervals at different stations throughout the island. Our readers are aware that an annual SHOW, FAIR AND SPORTS specially for the benefit of native agriculturists in connection with each Kacheheri, has long been advocated by us as a most desirable innovation. But we are aware of the difficulties in the way. Most of these would be removed if there were an Association with permanent plant which could be utilised for any station where a Show was projected. Such an Association with a fixed Committee and Rules could make the arrangements a much easier matter for the Provincial or District Agent, and there would then be no chance of one Show clashing with another. Shows of the extent meditated if held once in three years at most stations, could be supplemented in between with purely native gatherings in the shape of a Fair and Athletic Sports under the patronage and guidance of the "Agent-Mahatmaya." An over-true complaint of the natives is that the British Government which has given them Law Courts, Police Stations, and Arrack Taverns, has done nothing for the innocent amusement of the people in fixing Holidays with attendant Sports (free of gambling!) and if possible Shows of Stock and Produce, while the requisite Fair would be sure to come in of itself.

RICE FROM SOUTHERN INDIA.

The thanks of his brother planters are certainly due to Mr. James Ryan for his exertions to make all clear about getting rice readily

from Southern India. Unfortunately, to all appearances, we are on the eve of something like a Famine in the Madras Presidency counterbalanced by abundant—even superabundant—crops in Bengal and Burma, whence therefore, it is evident our wants are shortly bound to be supplied. Madras Presidency, we fear, will require all the rice grown within its borders for some time; and indeed we may anticipate a rush of coolies to Ceylon early next year if the scarcity extends—so that a plentiful and cheap supply of labour should be the rule in the Spring of 1898.

THE SOY BEANS.

The Madras Government sends us a paper showing how Surgeon-Lieutenant-Colonel W. G. King, M.B., C.M., D.P.H., Sanitary Commissioner for Madras, addressing the District Medical and Sanitary Officer, Vizagapatam, the Deputy Collector of Bellary and the Tahsildar of Saidapet, on 8th September 1897, says:—

I have the honour to forward herewith oz. of soy beans, with the request that you will kindly cause them to be sown in any suitable place where they can be carefully watched as to progress of growth, and that you will oblige me by stating the nature and amount of crop obtained and whether you think the beans can be grown successfully in your district from the experience so obtained. I need not remind you that the "Soy bean" is probably the most nutritious form of readily assimilable pulse at present known, and that, should it prove possible to introduce it widely in this Presidency, it would prove of great advantage in jail administration and also to the poorer classes generally. The enclosed extract from "Church" will show you the method of cultivation and the various uses to which both the seed and the stalk can be put. 2. As this is a suitable period of the year for sowing, I trust you will oblige by taking action in the matter as soon as the seeds are received. In asking you to kindly undertake the experiment, I may state that it was only after long and persistent search in India and Burma that I have ultimately obtained specimen.

THE SOY BEAN.—This crop is generally grown by itself; the seeds are sown from June to September; the harvesting takes place between November and January. It is consequently a kharif crop. The seeds should be placed at a depth not exceeding 1 to 1½ inch; 18 plants may be left, after weeding and thinning, to the square yard. A peaty soil, or one rich in organic matter, suits the plant best; a calcareous soil is also favourable to its growth. Sulphate of potash is a good manure; nitrogen may be supplied either as nitrate of soda, or, in the case of soils poor in organic matter, in the form of rape or mustard cake, but it is rarely needed, while large applications of nitrogenous manure exert a distinctly injurious effect upon the yield of beans. So far as we know, this very important, vigorous and productive pulse is not attacked by any insect or parasitic fungus.... That composition entitles the soy bean to the highest place, even amongst the pulses, as a food capable of supplementing the deficiencies of rice and of other eminently starchy grains. Very few vegetable products are so rich as this bean at once in albuminoids and in fat or oil, the former constituent amounting on the average to 35 per cent, and the latter to 19.... In China and Japan three preparations are extensively made from the soy bean. Soy sauce is the best known of these, but more important are the soy or bean cheeses, and a kind of paste. The beans are sometimes pressed for the sake of the oil they yield; the residual cake forms an extremely rich cattle food, containing as it does 40 per cent. of flesh-formers and 7 per cent. of oil. The soy bean may also be grown as a fodder plant. If cut just when the pods are fully formed, it makes an excellent hay, superior to that of the lentil.

COFFEE IN MEXICO.

In continuation of our remarks yesterday, we may add that it will be interesting to Ceylon and Indian coffee planters and ex-planters to hear of the great interest which is at present being taken by "Britishers" in coffee cultivation in Mexico. In that country the coffee industry is now making rapid strides and coming well to the front. It has been known for some years that there existed in Mexico vast tracts of the finest coffee land, but it is of comparatively recent date only that the exploitation of coffee in that country has been taken up in a scientific and well-organised manner.

The recent visit of experienced Ceylon planters did much to open the eyes of both London merchants and Ceylon planters in London, to the immense advantages that Mexico offers for the cultivation of the bean; and during the last few months an influential Syndicate has been formed of merchants and planters in London, with a view of acquiring and working some of the promising plantations and of opening up new lands for coffee. Not three but four experienced Ceylon men, viz., Messrs. John Clark, Cecil O. Nafel, J. G. Fort and P. F. Hadow are now in Mexico on behalf of the Syndicate and should their Reports, as it is expected they will, confirm those already in the hands of the Syndicate, it looks as if a very big thing were likely to come out of it. Possibly this may prove the finest chance that Ceylon planters have yet had to take up their old favorite industry in a new country and those first in the field will no doubt obtain the pick of the land.

We understand that the name of the Syndicate is the "MEXICO PRODUCE & ESTATES SYNDICATE, LIMITED," of 138, Winchester House, London, E.C., and any Ceylon man interested in the matter cannot be wrong in placing himself in communication with the Secretary.

CEYLON TEA IN AMERICA.

The "tea campaign" of Ceylon and Indian planters in the United States, is certainly beginning to tell when Messrs. Gov, Wilson and Stanton can send us such satisfactory figures as those which are appended to their letter elsewhere. It will be observed that during the nine months up to 30th September last, the demand for Ceylon tea has increased by 50 per cent over the quantity taken for the same period of 1896. The Road Lane firm sum up the case for both Ceylon and Indian tea as follows:—

"The use of Indian and Ceylon tea in North America shows decided progress, being 8,464,749 lb. taken during the last nine months, against 5,562,994 lb. during the same period of 1896. This increase having occurred in face of somewhat obstructive legislation, the development is very gratifying. As these restrictions are likely to be removed there is reason to believe that the use of British grown tea will become even more general."

For the whole year 1897, we may hope that the total of Ceylon tea taken will not fall much short of 6 million lb., and of Indian, 5 million or 11 million lb. of both and the improvement ought to go on steadily year by year now, seeing that the taste is spreading for sound teas among the people of the United States.

COFFEE PLANTING IN EAST JAVA :

"WHY GO TO MEXICO?"

This is the question asked of us today with reference to our article on Mexico. "Why should young planters in Ceylon with some capital go across the seas to far away Mexico, when there is far better scope and encouragement near at hand in East Java?" We have had the pleasure, through Mr. Fairweather of Yataderia, of meeting the pioneer of coffee in East Java. This is Mr. Frank Adam with 23 years' experience of Java and the Straits and who has just come from Barmah on a month's visit to the Ceylon planting districts. Mr. Adam goes to Yataderia tomorrow, and afterwards he will visit his cousin, Mr. Mooyaart-Denison in Kandapola, and Messrs. F. and W. Stewart Taylor, Passara, and see some of the estates in Hapitale, Passara, &c. Mr. Adam first thought of coffee in Banjoe-wanjie, East Java, in 1890, but he was scoffed and laughed at for going so far afield, to a district separated by 30 miles of "wilderness" from the occupied parts of the island. However he persevered, and the result now is some of the finest coffee plantations seen in Java (*notably that of Glen Nevis*), in the opinion of competent Ceylon and Java men; a capital road all the way, apart from steamer communication; and while labour was 90 cents (of a guilder) per man per day, to begin with, it is now down to 45 to 50 cents or 10d per day. Mr. Adam would fain see more Ceylon men turn their attention to East Java; and it must indeed be a certain proof of labour being abundant, that we find Mr. Fairweather and his partners seconding this proposition! For, what has been the cry for years in Ceylon; but that "a good thing is no sooner found than it is spoilt by too many hearing of it." Here, however, we can assure young capitalist-planters that they will be welcomed to East Java and that the advantages in rich land, good labour, easy rent and taxes—nothing to pay for five years and then about 2s 3d per acre rent with 2 per cent tax on produce—seem very decided indeed. We have no doubt that Mr. Adam while in Ceylon will be very glad to give information to any applicant. The Company comprising Messrs. Fairweather and Storey have 4,000 acres land with 1,000 in coffee; while Messrs. Talbot and partners have 300 in coffee out of 1,000 acres. One coffee crop is reported at 5,000 piculs (136 lb. each) of coffee, and that 1,000 of these cover expenses; while the coffee as cured is ranged with "M. P. Ceylon" at 100s per cwt.!

PLANTING NOTES.

RAMIE FIBRE.—Messrs. MacDonald, Boyle & Co., of 39, Victoria Street, S.W., write in reference to a note on "Ramie Fibre," that appeared in these pages recently, that we must have been misinformed. The Midlands Spinning Co., of Long Eaton, have been working Ramie under their process for the past four years, and tons of the yarn have been turned into lace and other materials. —*Gardener's Chronicle.*

THE EFFECTS OF EARTHQUAKE ON TREES.—Two or three correspondents of *Indian Gardening* says that since the earthquake in June the fruits on their Papaw-trees have not increased in size nor ripened, but remain in the same state as before the earthquake. New growth, however, and a fresh crop of fruit has been produced since the catastrophe, leaving the previously-formed fruit arrested.

OUR RICE TRADE.

Mr. JAMES RYAN writes:—

"Re your article 'Our Rice Trade' (4-12-97), Mr. James Gibson does not bother whether Coast Rice arrives in bags of one size or another; but this matter is one which intending purchasers from the Coast must take particular note of. The consolidated rate of the South Indian Railway is the same for a large bag or a small one, provided the weight does not exceed 190 lb. gross, and it is this concession that enables the purchaser to land Rice at Bandarawella $14\frac{1}{2}$ cents per bushel cheaper than Mr. Gibson's sea-borne Rice."

The experiment of getting rice from Tanjore in the way pointed out is certainly one well worth trying; although we cannot think that the supply will continue available at the low rate while famine prevails in another division of the same Presidency.—Mr. Frank Adam, just come from Burmah, confirms today the report of a large rice crop, and says when he left Rangoon "paddy" was being shipped, he understood, to Tuticorin or Colombo.

CEYLON TEA IN AMERICA.

Writing from New York, 5th November, the Tea Commissioner sends us the following extract from a Metropolitan Journal:—

A DIRECT LINE TO INDIA.

A Regular Service to be Commenced this Month.—A regular direct steamship service between this port and India has just been arranged for, the first sailing being set for November 27th, by the "Sahara," a vessel of 4,089 tons, going via the Suez Canal and taking freight for Aden, Persian Gulf, Bombay, Malabar Coast, Ceylon, Madras and Calcutta. She will be followed by monthly steamers. The new service is of especial interest, inasmuch as it is the first direct regular line to India from New York. Most India business has heretofore been handled via Great Britain and Mediterranean ports, with occasional sailings by tramp vessels. The new line is established with the definite purpose of developing trade, the agents and managers believing that present trade conditions were ripe for the enterprise, and also feeling confident that with regular facilities the trade will increase. The advantages will be especially felt by American manufacturers, who can thus sell on samples, and conduct their business with greater convenience. The outward cargoes will naturally be of a more or less general character, but steel rails and railroad material will figure as one of the most prominent items.

Bucknall Bros. of London are the managers of the new line and Norton & Son, the New York agents.

He adds:—"This cutting from the *Journal of Commerce* here, will interest your readers. It should also benefit the Colombo market, as our kith and kin here dearly love direct trading, and hate everything that looks like supporting London trade. The recent rise in the tea market in Colombo and London, has made importers here very angry. They were beginning to think Ceylons were permanently down to the level of common Chinas. It is the large quantity of insipid pointless teas made in April and May, that depresses the market, and gives cause to men to sneer at Ceylon quality. Why do planters make so much at that season? Better prune more in March, as quite half the April and May teas showed no profit this year."

But is it not evident that cheap teas in America may benefit our planters in the end by enabling a wide dissemination and when once the "taste" is got, we may expect the enquiry to be for Ceylons?

PRODUCE AND PLANTING.

BRITISH GROWN v. FOREIGN PRODUCE.—This question of British grown versus foreign produce is of interest to tea as well as sugar planters, because it has often been stated that the consumer of produce desires to give his own countrymen the preference when he can, and that this has been a factor in the development of the Indian and Ceylon tea industry. We fear that in the case of sugar the facts do not point in this direction. The *St. James's Gazette* recently instituted some inquiries as to the part the consumer played in the matter of cane sugar and beet. As a result the special commissioner who made inquiries says: "In the first place the average purchaser rarely knows what she is buying. This applies to pretty nearly everything. When English-women go shopping they place themselves almost entirely at the mercy of the shopkeeper. They do not know the quality or the origin of the goods they buy, and when they take the trouble to ask, which is seldom, the shopkeeper, who is often equally ignorant, may tell the truth or not as he pleases. What they care about is not quality or origin, but cheapness and appearance; and of the two the upper classes are more taken by the cheap, the lower by the pretty. If they care about any other consideration it is the name attached to a thing, either because it has traditional value or because it is much advertised.—*H. and C. Mail*, Nov. 19.

PLANTING NOTES.

FIJI AND THE NEW HEBRIDES.—Mr. R. B. Heinekey, of Colombo, has, says the local "Times," recently returned from Fiji travelling via New Caledonia and the New Hebrides. In New Caledonia Mr. Heinekey found the French Government encourages the growth of coffee, giving free grants to new arrivals of good character. In the New Hebrides coffee is as yet only in its infancy: and the coconut plantations are not good. With regard to Fiji we are told it "has always been a sink for money. Many men have taken money into the country, but it is not on record, any one has ever taken money out of it by planting." Coffee is a failure, but sugar (under an Australian Company) is doing well, while copra is a large industry. Messrs. Lever, Bros., of Sunlight Soap fame, who have a mill at Sydney, crush 10,000 tons a year. Poonae realises £4 10s a ton in Australia. The conditions for tea in Fiji are favourable, but labour is very costly.

A PAMPHLET ON "BERMUDA LILY DISEASE" has reached us. A friend who has seen it, writes:—"This disease is also very troublesome in English gardens. Various remedial measures have from time to time been tried though none, of course, with permanent success, the disease being a durable form of fungus. Its evil effects can, however, be combated to a great extent by soaking the bulbs before planting, in strong solution of Condy's fluid. But it is the minute 'mite' insect that gives most trouble; such applications as soft soap and sulphur, quassia solution, and carbolic acid solution, have frequently to be resorted to diminish its numbers. In Bermuda, where lily bulb-farming is a considerable industry, the disease seems to have made itself rather severely felt. But we need hardly fear its depredations in Ceylon, for, outside of the Botanic Gardens the lily is seldom, if indeed at all, seen. Even at our higher elevations the climate is such as makes the cultivation of this beautiful (and profitable, when grown for market class of plants almost impossible."

THE CEYLON GENERAL TEA ESTATES, CO., LTD.

This Company has just been floated principally through the agency of Messrs. W. H. Davies & Co., to acquire, we believe, the following estates:—

Estate.	District.	Full bearing.	Young tea.	Reserve, &c.	Total acres.
Penrith	Kelani Valley	361	79	368	808
Logan	"	202	36	50	288

Under Tea		.. 5,709			
Reserve		.. 3,607			
Coffee		.. 143			143

Total Acs. (about).. 9459 Acs. 9,459
 Share capital, £400,000; divided into 40,000 six per cent. cumulative preference shares of £5 each £200,000 (which are preferential as to capital as well as dividend); 40,000 ordinary shares of £5 each, £200,000; and 1,400 five per cent. first mortgage debentures of £100 each, £140,000.

PRESENT ISSUE.—27,000 preference shares, £135,000; 23,000 ordinary shares, £115,000; 1,400 first mortgage debentures, £140,000.

The purchase price to be paid by the Company for the above Estates, free of encumbrances, has been fixed by The Malabar Company, Limited, who are the Vendors, and are selling at a profit, at £363,500, payable as to £45,000 in fully-paid Preference Shares, as to £38,330 in fully-paid Ordinary Shares and as to £280,170 in cash, leaving the sum of £26,500 for Working Capital, which is considered quite sufficient. In part payment of the purchase price the Vendors have agreed to take one-third of the present issue of both Ordinary and Preference Shares, which is the limit allowed by the rules of the London Stock Exchange. The Vendors will discharge all outgoings belonging to the season 1896-97 in respect of the Gonamotava and Berragalla Estates up to the 1st day of Sept, 1897, and in respect of the other Estates up to 1st October, 1897, from which respective dates the Company will take possession and will be entitled to the profits. The Vendors will pay all expenses of and incidental to the formation and registration of the Company up to the first general allotment.

AUDITORS.—Messrs. Broads, Paterson & Co., Chartered Accountants, No. 1, Walbrook, E.C.

SOLICITORS.—Messrs. Harwood & Stephenson, 31, Lombard Street, London, E.C.

BROKERS.—Messrs. W. I. Carr, Sons & Tod, 2, Royal Exchange Buildings, E.C.

BANKERS.—The Commercial Bank of Scotland, Limited, 62, Lombard Street, London, E.C. Head Offices, Edinburgh, and Branches; National Bank of India, Limited, 47, Threadneedle Street, London, E.C.

AGENTS IN Ceylon.—Messrs. Carson & Co., Colombo.

MANAGING AGENTS AND SECRETARIES.—Messrs. Rowe, White & Co. and Registered Offices of the Company, 16, Philpot Lane, London, E.C.

For the past season, the crop is returned by the Estate Inspectors or the owners at lb. 1,896,917 of tea

The production for the current season is estimated by the Estate Inspectors or the owners at 2,361,900 "

The large increase in the estimated crop for 1897-98 is due partly to the acreage of young Tea that will come into bearing, and partly to the natural rate of increase in the Tea in bearing though not yet fully matured.

The Directors believe that when all the young Tea is in full bearing the yield should, on very moderate estimate, be 3,065,800 "

From a careful consideration of the figures given in connection with the Estates, the Directors consider that the following calculation is a reasonable one.

For the current year, taking the Tea at the moderate average selling price of 7½d per lb., and the cost thereof laid down in London at 5d per lb. at an exchange of 1s 4d per rupee the net profit of 2½d per lb. is the result. This on a crop of 2,361,900 lb. is equal to £24,603

The profits from the sale of Tea Seed are estimated at .. 2,500
 " " Coffee .. 2,686

" " Tea bought and manufactured for adjoining Estates are estimated at .. 1,700

Giving a total of .. £31,489

The interest on £140,000 debentures at 5 per cent will absorb .. £7,000

Dividend on £135,000 preference shares at 6 per cent. will absorb .. 8,100

London expenses, estimated at .. 1,250

Leaving available for dividend on the ordinary shares £15,139

which, it will be seen, is sufficient to pay 10 per cent on the present issue, and leave a balance available for Reserve, &c.

It will be observed that a strong feature in this undertaking is the large proportion of young tea, which, each successive year, should bring increasing profits to the Shareholders, and that there is also an ample reserve of land for further extensions. There is also a steady business in the sale of tea seed from the Clova-Sana Estate.

AN ECONOMICAL MOTOR FOR TEA FACTORIES.

The following is a copy of a report from Fairfield estate to Messrs. Davidson & Co.:—

Cost of working half a cent per lb. of tea made.

A report has recently been received by us regarding the cost of working a Tangyes patent eight horse-power oil-engine supplied to Fairfield estate, Peermad, South India. The trials of the engine, which extended over a period of three months were carried out under the supervision of the Superintendent of the estate, and the figures here quoted have been authenticated by him.

The engine is a Tangyes' eight horse-power engine, and the oil used is ordinary Russian "Daylight," the contents of one case (two tins) being about 65 lb. oil say nine gallons.

This oil was purchased at Alleppey, and had to be transported to the estate for 12 miles by boat, and about 60 miles by bullock cart, a total distance of about 72 miles, the cost of which is included in the figures below. The total cost of oil consump-

tion on the estate per lb. of made tea was as follows:—Date May, 1897; total days worked, 29; Average hours worked per day, 4 hours and 58 minutes; total tea sifted, 11,013 lb.; total tea manufactured, 9,908 lb.; quantity of oil consumed, 14 cases; cost per lb. of tea made, 1.32 pice '67 of a cent.

In a similar manner during the month of June, the cost per lb. of tea made was 1.17 pice. '60 of a cent.

For the three months ending 30th June 1.30 pice—'67 of a cent. The oil consumption in each case includes the cost of all oil used for the factory lamps, and all wastage and loss that may have occurred in addition to the cost of transporting it for 72 miles.

The actual cost of the oil required for driving the engine itself may therefore be reckoned at about $\frac{1}{2}$ a cent (Ceylon coinage) per lb of made tea.

CEYLON TEA IN RUSSIA.

INTERVIEW WITH MR. W. JORDAN.

Mr. W. Jordan, of Messrs. Jordan & Co., Talawakele, while recently in Europe, paid a visit to the Baltic and to Russia. In the course of an interview with a representative of the *Observer* Mr. Jordan gave a good many particulars respecting Ceylon tea and the progress made in Russia with its sale.

"What," asked our representative, "were your general impressions?"

"I went to Russia expecting to find them a very rough people, on an equality with the Turks, semi-civilised, but I came away with a very different opinion. The country is certainly ruled by an iron hand, but it is a great country and there are a great many tribes, some of them very warlike and difficult to control. We found the people we came in contact with, exceedingly courteous and willing to render us any help they could, though we certainly might have been watched but we did not know it."

"How did you travel from England to Russia?"— "By the steamer 'Ceylon,' an old P. and O. boat under the command of Capt. Roach. We called at Elsinore (where we looked in vain for Hamlet's ghost), Copenhagen, Stockholm, Cronstadt, and then (having satisfied the authorities that our passports were in order) to St. Petersburg, Moscow (400 miles distant) and Nijni Novgorod, a farther journey of 280 miles. At the last place a fair was on, and also the great Pan-Russia Exhibition. I was the only of the party connected with Ceylon. We travelled under the auspices of the London Polytechnic and altogether journeyed 4,820 miles at a cost of eleven cents per mile."

"And how then about Ceylon tea?"—"Oh yes? That was my chief reason in visiting Nijni Novgorod. Previous to going there, I called at the Ceylon tea shop in Moscow, which is under the management of Mr. Rogivue. Unfortunately it was a feast day and the shop was closed, but I saw that it was situated in a crowded thoroughfare and that there was a good exhibition of tea and advertisements of tea in the windows. At Nijni Novgorod the Ceylon tea-house was outside the exhibition, which, being a Pan-Russian Exhibition the authorities would not admit anything from Ceylon. The kiosk was situated in the main street leading to the chief entrance to the Exhibition and there passed by it millions of people, that were visiting the Exhibition from all parts of Russia, a very motley crowd indeed. It was a very good kiosk and there was a capital exhibition of tea. It belongs to Mr. Rogivue who deserves the greatest credit for displaying our teas in so attractive a way. We found Mr. Rogivue was not there, but we

saw his manager, a polished Swiss, quite a linguist, who was very kind and entertained us, supplied us with cups of good Ceylon tea, gave us all the information he could and took us round the Exhibition. There were then four shops in Russia for the sale of Ceylon teas and they not only gave samples away, but actively showed the people who visited them from time to time how to make tea properly. In the Exhibition itself, though we found no tea, we saw large placards on the tram cars advertising Ceylon tea."

"And about tea-drinking in Russia?"—"As regards the consumption of tea you must bear in mind the Czar rules over 120,000,000 and they have not to be weaned from drinking coffee or stronger liquors, but are actually tea-drinkers now. In Russia the usual refreshment offered a visitor is the glass of tea or 'chai,' as it is called. They produced to us two teapots, the small one contained the freshly made infusion, and the other, a larger one, containing boiling water. Glass tumblers were brought in with electro-plated handles and a small China tray containing slices of lemon with a lump of sugar. The glasses were then rolled in warm water, replaced in the stand, and slices of lemon put in each with a small quantity of the tea infusion poured in the cup, which is then filled with hot water. The piece of sugar is then inserted in the mouth and the tea sipped through the sugar. The visitor can, if he likes, have a single glass of tea just like a man can have his glass of ale and the charge for it is about 3d. We saw large halls in which scores of the peasants of the country had tea, calling for little if anything else."

"But we are losing Mr. Rogivue?"—"Yes and I am personally very sorry, for he has had very valuable experience and if he had been properly treated he might have been still with us. I am not of the opinion that the more Indian tea that is sold in Russia, the more room there will be in England, for Ceylon tea. What we want to do I am convinced, whether it be in Russia, or on board ship, or elsewhere, is to show people how to make tea. An American lady only the other day praised the work our Association is doing in America in introducing Ceylon tea, holding lectures and showing how it should be made. I have made it personally on board ship to show fellow passengers how the tea should be dealt with and have met with great success."

"What about the future?"—"I should" (added Mr. Jordan) strongly recommend that there should be a good representative of our Association stationed in Russia, with sub-agents at Warsaw, St. Petersburg, Novgorod le Grand, Odessa, and Moscow, and also in Nijni Novgorod during the Fair. None but the best tea—Pekoe and Orange Pekoe—should be sold and the agencies established by us should not sell tea retail. Push and publicity by means of advertisement would do much: samples should be freely given away. Mr. Lipton has made his special teas known throughout the world, and why should not Ceylon teas be similarly established in public favour. Let them get to work at once, before Indian teas are permanently established and before the completion of the railway to China makes teas of that country cheaper in Russia. Ceylon tea can hold its own in Russia, if it is only made widely known and the man who can do this will deserve well of his fellow-colonists. For myself, interested as I am in this island, I am trying to do what little I can, in the direction of making our teas known and showing how they should be made."

CEYLON FISHING CLUB.

The annual general meeting of the Ceylon Fishing Club, was held at Hill Club, Nuwara Eliya, on the 27th Nov., when there were present:—Messrs. S. M. Burrows (in the Chair), C. H. Bagot, G. C. Ross Clark, John Fraser, and North C. Davidson.

Mr. Burrows then read the following report of the working of the Club during the past year.

The last annual meeting of this Club was held on September 12, 1896, and a report was read by the Hon. Secretary (Mr. Lushington). Subsequently three meetings were held—one on December 23rd, 1896, when the usual election of office-bearers for the ensuing year took place, and the accounts of the Club up to that date were laid on the table. A second meeting was held on March 1st, 1897, to discuss the distribution of the fry, and a third meeting was held on September 25th at the request of several members, and a preliminary report was submitted by the Hon. Secretary; the accounts up to date were laid on the table and passed, and the arrangements as to *ova* for the next hatching season were discussed.

RULES.

During the year the following rules were altered or amended. In Rule No. 1 page 2 the word "person" was deleted and the word "resident in the island" were substituted for it. The following words were added to Rule XI: "Sufficient notice of such proposed alteration or amendment shall be given to the Hon. Secretaries to allow them to give each member of Ceylon Fishing Club ten days' notice before the general meeting of such alteration or amendment." Rule III that licenses to fish for trout by non-members of the Club shall be at the following rates:—

One day (a)	R12:50
" week (b)	25:00
" month (c)	75:00
The whole season (d)	120:00

Rule V. section (b) was altered to read thus: "They shall at once return to the water all trout accidentally caught."

Rule VII: that "subject however to the exception contained in Rule No. 5 was expunged." It will in consequence be advisable to bring out a fresh addition of the C.F.C. rules. It was also decided to keep on, the present watcher, who has done good work during the year, in watching the local streams and lakes preventing poaching and prosecuting offenders, and to employ in a similar capacity the resthouse-keeper, Horton Plains and the Patiapola resthouse-keeper.

FISH REGISTER.

The fish register kept at the Horton Plains resthouse having proved successful and interesting, it was thought advisable to start similar books in Nuwara Eliya, and the Grand Hotel, the Club. St. Andrew's, and Keena Cottage, have each been supplied with one. It is hoped that fishermen will keep the Club by entering them up carefully. The Horton Plains register shows that 384 fish were caught by members between February 15th and August 22nd, of which 216 were under 11 inches, and were returned to the water. The largest fish taken was one of 3½ lb. caught by Mr. A. T. Cathcart; while 8 fishes were caught between 2 and 2½ lb.; 70 between 1 and 2 lb. and 89 between ½ and 1 lb. Unfortunately there is no register of fish caught in Nuwara Eliya though it is hoped that this will be remedied by next year.

CLOSED SEASON.

The alteration of the dates of the close season has been discussed, but no definite conclusion has yet been arrived at. It is a difficult question on which everybody defers. The fact is, we none of us know much about the breeding habits of trout in these waters, and of the alteration in their habits caused by change of climate, food, etc., because we are most of us busy men who have no time to devote to the close daily observation necessary for such a study. A leisured man with previous experience who would take up the matter as a hobby would be a real God-send. Two

stewpounds were made early in the year—one by the kind permission of H.E. the Governor in the grounds of Queen's Cottage, and one under the superintendence of Mr. Farr at the Horton Plains. It is too early yet to pronounce whether they are a success or a failure. Fry were supplied to each but the Horton Plains pond, was seriously affected by a heavy flood. Queen's Cottage pond, has been undisturbed and it will be dragged early next year before fresh fry are put in, to ascertain how the last year's fry have fared. A great many female trout full of spawn were sent to us for inspection by the fishermen who caught them in July and August, but hardly any waters were caught then with signs of milt in them. Every effort was made to discover signs of fish working up towards the headwaters in pairs or of females depositing eggs in the sand, and the removal of sand and rubble from the upper parts of the streams was prohibited for several weeks in order to keep the waters as undisturbed as possible. But it cannot be said that so far there are any certain proofs that the trout are spawning in the Nuwara Eliya streams. An experienced member and former Hon. Secretary of the Club is of opinion that they never will and that our one hope of spawning lies in the Horton Plains streams. On the other hand our streams here are not much warmer than, or very different from, some of the streams in New Zealand, where it took from ten to twelve years before the fish would spawn and the power of adaptation to environment, talent in all animals, trout included, is well worth waiting for and endeavouring to encourage.

THE YEAR'S RECORD.

Under this head the year's record has been disappointing to the verge of disaster. 40,000 *ova* were ordered out at the end of 1896 from the usual source—the Surrey trout farm of the Messrs. Andrews. They arrived in two batches in January and February. Every possible precaution was taken to ensure their immediate delivery and rapid transport to Nuwara Eliya. The hatchery and trout house were in excellent order, the latter having been doubled in size. Unfortunately, Messrs. Andrews experienced great difficulty in finding properly appointed steamers to carry the *ova*, and in order not to miss the dates they shipped them by vessels where there were no proper cold rooms and no sufficient store of ice. Nor were the boxes left undisturbed, but had obviously been turned up on end, and shifted about ruthlessly. The result was that the last batch was ruined and the second batch being nearly so. The eggs when unpacked instead of lying flat were found crushed together into a horrid mass of corruption and it took many hours' hard work, day and night to extract the possible survivors. They, however, were so hopelessly affected by the corruption of their neighbours, that fungus set in almost at once and spread with fatal rapidity; so that eventually only 1,506 fry, were hatched and were distributed as follows:—200 to Ambawella Oya; 100 to Queen's Cottage Stewpond; 499 to Nuwara Eliya streams; 400 to Buluhalu Oya and Kurundu Oya; 500 to Horton Plains' streams and Stewpond. It is a disappointing result but it is useless to cry over spilt milk as over spilt *ova*. Messrs. Andrews, reduced their bill by about ½rd, and have promised to be more careful in future as to shipping the *ova*, and it is hoped that arrangements have been made as regards the coming batches which will prevent the recurrence of such disasters. It may be some slight comfort to know that we are not the only Club that has to face such disappointments, for the annual report of the Nilghiry Game and Fish Association has a very similar tale to tell, and even heavier losses to deplore. If it were necessary further to prove that "the best laid plans of trout and men gang aft a-glee" two slight incidents might be mentioned which confirm the theory. As it was an abnormally warm season when the *ova* arrived, we telegraphed to Colombo, for ice to lower the temperature in the filter boxes. It arrived packed in kerosine tins, and so impregnated with oil that none of it could be used. Again about 40 of our few surviving fry suddenly died in 24 hours of no perceptible cause except a small red spot on the gullet. A careful search through

the troughs disclosed the presence of 3 or 4 leeches and if they were really the cause of the loss another terror is added to the troubles of tropical trout breeding.

FINANCE.

The financial condition of the Club is quite satisfactory. After paying for the unlucky *ora* and meeting two abnormal and heavy charges, the rebuilding of the hatchery and the making of the stowpond at Queen's Cottage, the balance to our credit today is R1,230.91. Our income has steadily increased both in the way of subscriptions and licenses in spite of the manifold claims upon the purse during jubilee year: and, as far as one can judge, the average fisherman finds quite enough sport, to justify his expenditure.

Mr. Burrows' Report was received with applause. INTERESTING REGISTER OF TROUT CAUGHT.

The following postscript was added by Mr. Burrows to it:—"The two following records of a year's fishing in the Nuwara Eliya and Horton Plains streams have been kindly supplied by two members, and are published here, as giving a fair average of possibilities." Mr. Burrows added this postscript in consideration of the following letter addressed to him and a promise by Mr. John Fraser, of Abbotsford, to give a register of trout caught by him:—

Calsay, Nanu-oya, November 24th, 1897.

S. M. BURROWS, Esq.

Dear Sir,—Herewith please find a register of trout, caught by me in season 1897, which includes fish caught at Nuwara Eliya, Hortons, and Ambewella.

1	Trout weighing	lb. 4
1	do	lb. 1½
3	do	lb. 1½
4	do	lb. 1½
11	do	lb. 1
29	do	from 8 oz. to 15 oz.	
49	do	equalled 46 lb. 9 oz.	
29	trout returned,	under 11 inches.	

Last year, I was requested to send in an account of fish caught, and do so again, as I think it is interesting to know the number of fish caught in each season.

G. C. ROSS CLARKE.

The following Committee was appointed:—General Committee—newly appointed—Messrs. North C. Davidson, G. C. Ross Clarke, F. L. Clements; old members re-elected—Messrs. C. H. Bagot, A. F. Brown, H. G. Cuff, J. E. A. Dick-Lauder, T. Farr, E. Jeffries, E. M. Leeffe, H. V. Masfield, J. M. Purdon, J. H. Starey, A. R. Wilson-Wood, C. P. Hayes, C. Bayley, J. Fraser, Capt. R. Ward Jackson, and G. M. Fowler. Managing Committee:—Messrs. T. Farr, H. V. Masfield, Wilson-Wood, and C. H. Bagot, with Messrs. S. M. Burrows and J. Wickwar as Managing Secretaries.

THE AMSTERDAM CINCHONA-AUCTIONS.

The cinchona-auctions to be held at Amsterdam, on December 9, will consist of 8,216 bales and 626 cases Java bark. The stock in first hand, including the above quantity now consists of 1,715 packages Government and 8,022 private bark. These auctions will be the largest ever held anywhere, and it will be interesting to see if the market can stand this severe test of its strength.—*Chemist and Druggist.*

THE JAVA QUININE WORKS.

The Java-quinine-factory at Bandong, has now been a work for several months, but, like most new undertakings, it has had a good many difficulties to overcome. The first of these was, that extensive repairs were found to be required in the machinery (which had been purchased in Germany) almost as soon as it was put up. When that was done it was found that the producing-capacity of the work was inadequate to the probable demand upon the plant, and the factory had to be extended. The Dutch-Indian Government

in order to encourage the Java works, ordered 500 kilaos. sulphate of quinine to be delivered on July 1, but this order could not be executed in time, and had to be transmitted to Europe by the authorities—a fact which did not increase the prestige of the works. Now, however, the factory appears to have passed through its teething period, and is already trying to extend its operations beyond the Dutch East Indies. Thirty kilaos. of the Bandong quinine have been sent for sale to Singapore, where it was said (on whose authority we do not know) to be "better than Howards." Messrs. McNeill & Co., Samarang, Java, one of the firms who act as selling-agents for the Bandong works, report that the samples of the quinine which they have sent to their clients have everywhere given great satisfaction, and Messrs. MacLaine, Watson & Co., the selling-agents at Batavia, say that in the first week of October they received the following cablegram from London:—"Ship any quantity you can; we can sell large quantities up to 1s per oz." (At that time the London quotation of second-hand German quinine was 1s 1d to 1s 2d per oz.)

But the Java quinine works anticipate violent opposition from the European makers. They say that Herr Buchler, the director of the Brunswick factory, who visited Bandong just before the establishment of the works, publicly declared that if the factory were really started, the European manufacturers would kill it, even if they had to reduce the price of quinine to 6d. And it is held in many quarters in Java, that the great advance in cinchona bark which we are now witnessing is not due to the reduction of the bark-output, but to the deliberate policy of the great European manufacturers, who want to make the prices for cinchona bark in Europe so remunerative, that the Java planters will have no inducement to send their bark to the Bandong factory, to be converted into quinine. It is pointed out that two days before the Amsterdam sale of September 30, at which the unit advanced to 6.27c., a cablegram had been sent to Holland, announcing that the enlargement of the Bandong factory had been completed, and that the works were now able to turn out 100 kilaos. of sulphate of quinine a day.—*Chemist and Druggist.*

"FINE PLUCKING."

A Planter writes:—"You remember the denial of the charge of fine plucking which a correspondent of yours reported. Well! I hear that so fine are they plucking now that they give a name for 5lb! How that will pay remains to be seen."

ORANGE-GROWING NORTH OF KANDY.

A planting friend is good enough to write:—"I am sending into Kandy a box of Mandarin Oranges which kindly accept;—when grumbling some time ago about not being able to find a market, you expressed a wish to 'send some along' so here they are. We can grow this kind as the leaf fungus which is so fatal to the other kinds does not affect these so badly. Coffee leaf disease is a trifle compared with the white fungus attacking the orange, as the flush of young orange leaves is covered with the fungus the instant they appear, never giving the tree a chance to put on fresh leaves and it dies gradually. I have had hundreds of the large green orange trees killed by it and a good many Mandarin from this, and some other cause, a borer I think—were it not for this I could have flooded the market with oranges. I sent some of the fungus to Dr. Thwaites, years ago. His reply was collect and burn—it is very deadly, I quite agree with the verdict. I know nothing so terribly fatal to cultivation."

We have to thank our friend for a treat, shared with several invalids. The oranges arrived fully ripe but all in good condition. As to the fungus, our correspondent should send specimens to Mr. Willis or Mr. E. E. Green. The lady-bird beetles cleared the orange trees in Hawaii and California of bug.

TREATMENT OF TEA IN LONDON WAREHOUSE.

INFORMATION of interest to planters appears in the proceedings of the latest meeting of the Indian Tea Association in Calcutta, from which we quote as follows:—

The London Secretary stated that from enquiries made he found that it was not now an uncommon practice to leave the process of bulking the tea to be done in London, notably by several well-known concerns, presumably with the object of avoiding claims, although in the opinion of the trade it had been avowed that a decided preference is given to teas bulked on the factory. He considered that it was much to be desired that a continued effort should be made to lay down tea in London in such a condition that it might be kept untouched without risk of deterioration owing to the humidity of the climate.

In reply to a letter of enquiry on the subject of the use of machinery in repacking tea, the Managing Director of Bntler's Wharf wrote to Mr. Tye as follows:—

"We do not use any machines for repacking teas. It has been an utter failure at the London tea Warehouse. We fail to see how an average sample of tea can be drawn from any machine packed chest. All bulked teas are weighed gross, and nett, both under the supervision of Her Majesty's Customs; teas not bulked are weighed gross, and average tare fixed by Her Majesty's Customs."

In this connection the Secretary was instructed in writing to London to embody the remarks made by Mr. Traill, when the letter was in circulation, which were to the effect that the Association should press for nett weight of all teas turned out for bulking in London. Nett weight meant the actual weight of the contents of each chest, and not as at present, weighing the chest gross, deducting fractions of a pound, then turning the tea out and taring the chest, taking any fraction of a pound as a full pound. By this system it is quite possible for the Customs' weight to show 1 lb. 15oz. less than is in the chest. There is no doubt that many claims for loss in weight are largely due to this antiquated and unfair method of weighing. It was presumed that the wholesale dealers could not reasonably object to a system that would ensure their getting the weights of tea they paid for.

THE POSITION OF CITRONELLA OIL.

Buyers are afraid to purchase on speculation any longer, and unless they have firm orders in hand they prefer to await the further development of things. This is particularly the case in some essential oil markets, especially citronella oil. The position of this oil at present appears to puzzle most people in the trade, and those supposed to be in "the know" can only surmise, only guess at the real cause of the present spurt in Ceylon. Prices there have risen in an incredibly short space of time from about 11d per lb. in drums to 1s 5d c.i.f., and it is extremely doubtful whether oil even at this figure would be procurable in Galle, the principal port for citronella oil, whereas herein the open market it would be difficult to find a buyer over 1s 2½ c.i.f. Abnormal circumstances only can have produced such an extraordinary market in the East, for there has not been a shortage of supplies or unfavourable crop report, nor has the equilibrium of the market been at all upset by a strong demand from Europe or America. In fact, all along the belief has been current that both dealers and consumers were well stocked. This belief in heavy stocks, we are inclined to think, is mainly responsible for the boom now prevailing in Ceylon, inasmuch as it has induced some shippers, and even dealers, to enter upon a bear tactic, and the attempt of these bear operators to cover their open engagements has been instrumental in creating the belief in Ceylon in a large bear account. Prices rose rapidly, supplies were withheld from the bazaars, and a veritable corner for prompt

and near months' shipments was established, to the great dismay of the few bear operators. Some of these speculators have been caught nicely, and have to pay heavily for their speculative operations, but it is comforting to know that the number of these luckless bears is a small one, consisting as it does to the greatest extent of dealers. To London dealers it will be somewhat gratifying to know that some of the Liverpool speculators are involved as well, gratifying inasmuch as they are accused by London dealers of having spoiled the market on various occasions by unjustifiably low sales. London must, however, not forget that Liverpool, with its large soap factories, is a staunch supporter of the citronella oil trade, in fact, only since the development of the Liverpool, or, rather, Birkenhead soap factories, has citronella oil attained the importance it now enjoys. To judge from indications from Colombo, it would appear that we have at last reached the highest price, offers under 1s 5d c.i.f. are invited, and, although some sanguine people talk of 1s 9d c.i.f. we have little doubt that as soon as the bear accounts have been covered in, Ceylon will recede quickly, and by the beginning of the new year, we shall see the old range of prices again.—*Commercial Record.*

PLANTING NOTES.

"WARA" FIBRE.—A useful letter on this fibre and plant will be found on another page today, from a planter who has experimented to some purpose. It is quite evident that the cultivation of *calotropis gigantea* is worth a trial; but our correspondent "B" should tell us what he expended in labour, &c., for the quantity of cotton and fibre he sent to England.

ROYAL GARDENS, KEW "BULLETIN" of Miscellaneous Information. Appendix III.—1897. Contents:—List of Staffs in Botanical Departments at Home, and in India and the Colonies. For Ceylon we have:—Ceylon.—Department of Royal Botanic Gardens:—Director—John C. Willis, M.A.; Peradeniya, Curator, Hugh McMillan; clerk, J. Ferdinandus; draftsman W. de Alwis; Halkgala—Superintendent, William Nock; clerk and foreman, M. G. Perera; Henaratgoda—conductor, S. de Silva, Arachchi; Anuradhapura—Conductor, D. F. de Silva; Badulla—Conductor, D. A. Guneratne.—Appendix I—1898. Contents:—Lists of seeds of Hardy Herbaceous Plants and of Trees and Shrubs.

VANILLA-GROWING IN THE GERMAN COLONIES.—The German *Land und Plantagen Gesellschaft* of Kitopeni, near Bagamoyo, German East Africa, have set aside a large piece of land for the culture of vanilla. Part of this is already in bearing, but the crop this year has been very poor on account of the dryness. The plants want a moist soil and must have shade-trees, such as crotons or bananas to protect them from the sun and absorb the excess of moisture. The finest vanilla-plantation in German East Africa is that of the Catholic Mission at Bagamoyo.—*hemist and Druggist.*

TEA-GROWING IN THE CAUCASUS.—The new tea plantations at Chakva, in the Osurgentski Government in the Caucasus, have given most excellent results, and encouraged their proprietors to engage a number of Chinese experts to instruct the natives in all the intricacies of tea-growing. The last tea crop yielded ¼ lb. of tea for every bush planted, or 1,500 lb. from an acre having 6,000 tea plants on it. The whole available area for tea-growing is 20,000 acres therefore the total yielded could with ease be brought up to nearly 30,000,000 lb., which represents more than a half of the annual consumption of tea imported into Russia.—*Planters' Gazette*, Nov. 1.

TEA IN RUSSIA.—An interesting interview on this subject will be found on another page. Though praising Mr. Rogivue's work, it is evident that Mr. Jordan does not believe in establishing a rival business to the Russian dealers as the best means of making our teas known.

LAVENDER-GROWING IN VICTORIA.—Mr. N. A. Woolnough, who has a lavender farm in Moorabbinshire, Victoria, advises Australian agriculturists to take up lavender-oil distilling. He says that all the oil Australia could send to Europe for ten years would be but a drop in the bucket of European consumption, so that there is no danger of overstocking the market.—*Chemist and Druggist*, 13 Nov. 1897.

THERE SEEMS NO BOTTOM IN COFFEE—says the *Grocers' Journal*—highest grades maintain their position fairly well, but the lower have got down to incredible depths. This week the record has again been beaten, and while the market has taken it quietly here pretty well a panic has occurred in Amsterdam. Santos has been sold forward as low as 29s 6d., French rates being equal to about 30s; while Hamburg prices have shaded even these low figures, and Java in Amsterdam has been bought and sold at wide ranges in the excitement induced by reports of immense quantities in sight in Brazil.

COFFEE AT KOTAKOTA, B.C. AFRICA.—Fourteen or fifteen miles inland from Kotakota is the pioneer coffee estate on Lake Nyasa. The coffee was planted at the end of the last wet season. I was surprised to see how well it looked. The land is evidently well suited for coffee growing as the young plants look exceedingly healthy. The elevation is about 300 feet above Kotakota or about an elevation of say, 1,800 feet above sea level. This seems to suit the coffee very well. Labour is cheap here (as it is all the way up the coast of the Lake) the ordinary wages being 1s 6d a month (with a yard of calico a week food pay).—*B.C.A. Gazette*, Sept. 21.

WHAT IS PROSPERITY FOR A NATION?—It behoves all intelligent Sinhalese to ponder the answer:—"It is to have all its people at work. When all the people are at work the nation is adding to its wealth all that is possible in its day and generation. New inventions might have made it more, but for each year the labour of each nation is the sum of that year's creation of wealth." This is in a Hawaiian journal which adds:—"Teach the young Hawaiian lads, who are each year graduating from our high schools,—teach them how to care for coffee trees,—how to prune and handle them, how to pick and care for the berries. They are well suited for this work, in which hundreds of them may find steady and profitable employment."

LABOUR DIFFICULTIES IN FIJI.—In the "Fiji Times" of Oct. 9th, we find an order of the Commissioner for Native Affairs which shews what restrictions are placed on engaging natives:—

A circular letter from Hon. W. L. Allardyce, Native Commissioner, is published, in which Bulis are warned that married men are not to sign on to work for Europeans for a longer term than three months under heavy penalties.

We learn from an authority on Fiji Affairs that "Married men often engage to go away and work for a year, but they are prohibited from doing so by law, and if found out are liable to punishment. No married man is allowed to engage to work out of his district for a longer period than 3 months."

WOOD ASHES AS A MEDICINE.—In the *American Naturalist*, Mr. Stahl of Illinois extols the virtue of wood-ashes as a medicine for farm animals, and says that used with discretion no other remedy is required to keep animals in full health. For swine he makes a mixture of wood-ashes, charcoal, and salt, and keeps it constantly before them in a large box having holes in the bottom, through which the animals work it out as they require it. He also speaks well of the mixture for horses, and in thirty-seven years of experience of farm-life has lost only one horse, and that through an accident. The ashes may be administered by putting an even tea spoonful on the oats twice a week; but he thinks it preferable to place a mixture of three parts wood-ashes to one of salt constantly before the animal in a little compartment at one corner of the feed-box. Mr. Stahl also has great faith in the value of wood-ashes when used as a fertiliser.—*Journal of the Jamaica Agricultural Society*.

COFFEE IN MEXICO.—Our home correspondent elsewhere reports, not one, but two expeditions of Ceylon men to Mexico to see about "Coffee investments." Mr. Naftel appears to lead the one and Mr. Jas. Sinclair the other. Our readers are aware from letters in the *Observer*, of Mr. Wm. Forsythe (formerly of Maturatta) that European enterprise in coffee has been extending for some time back in Mexico; but with all the investments (on behalf of Ceylon men especially) in Brazil, Costa Rica, Java and the Malayan Peninsula, of late years, one would imagine that coffee had had its full share of attention. No doubt the troubles in Brazil over the Government and paper currency is an encouragement to invest elsewhere in our old staple.

THE CAMPHOR TREES of Japan, China, and Formosa are beginning to fail, and the United States Government have tried the experiment of growing camphor in Florida, with encouraging success. It is found that there is no need to kill the tree, as they do in the Far East, because the gum can be extracted from the leaves.—*Globe*.

VERY OBLIGING.—The Board of Tea Experts, recently appointed by the United States, who distinguished themselves by framing some obnoxious tea regulations, have found the task so tremendous that they have resigned in order, as they generously point out, that "other members of the trade" may "bring a more varied experience and wider range of interest toward perfecting the regulations of the new law." The report which the retiring members have fired off before seeking retirement is an outburst of collective wisdom. They do not seem to know much about tea and tea dust, but they are of an obliging turn of mind, especially towards China. The Chinese Minister having demanded a different standard for Canton teas, and a revision of the Board's rejections, the Board replies mildly that an endeavour shall be made to find specific standards more thoroughly satisfactory. With regard to Ceylon and Indian teas, it has been found that the effect of the sieve test has been simply to exclude high-class teas made from the youngest and finest leaves of the tea plant. The "Experts'" regulation has, therefore, been abandoned for more than two months past, and the Board can only plead that before that time "the difference between dust and needle leaf had not been sufficiently well understood." It is suggested therefore, that siftings from India and Ceylon teas may be resifted through a No. 26 sieve of thirty wire to separate needle leaf from dust. The Board made a show of objection to backing down on the question of the Hyson standard, but recommended, "That the examiners be instructed to compare all Imperials, Hysons, coarse leaf gunpowders, and extra young Hysons with the Hyson standard, and all other young Hysons and small-leaf gunpowders with the young Hyson standard.—*H. and C. Mail*, Nov. 12."

CRYPTOGAMIST FOR CEYLON.

Mr. J. B. Carruthers, who arrived at Colombo by the mail steamer "Himalaya" from England, last month, accompanied by Mr. Dickman of Wariapola estate has come out to Ceylon, we believe, to conduct new investigations into the cacao disease. Mr. Carruthers went up to Kandy, where he was expected to remain about ten days. Mr. Carruthers has not been appointed or engaged by the Government. The London correspondent of our morning contemporary says:—

The Colonial Office, being of a dilatory nature, shewed no inclination to appoint a Cryptogamist to inquire into the disease, so Mr. Dickenson has taken the matter into his own hands. I hope that Ceylon may benefit by Mr. Carruthers' visit; he has many qualifications for the work before him. He has for some time past been working with his father who was till quite recently Keeper of Botany at the Natural History Museum, S. Kensington, and is now Consulting Botanist to the Royal Agricultural Society. Mr. J. B. Carruthers has therefore had ample opportunities of acquiring considerable and varied experience, and I may say, has also been very successful in his treatment of several fungus pests here in England, especially in connection with larch trees. He is recommended by Mr. George Murray, the present Keeper of Botany at the British Museum (Nat. Hist.) as "thoroughly fitted by training by natural ability and by performance to carry out such an investigation" as that in connection with the Ceylon cacao trees,

It may interest such of your readers as are Presbyterians to learn that Mr. W. Carruthers, F.R.S., the father of this rising cryptogamist, combines with the highest scientific attainments in his own special branch a very pretty knowledge of the "Shorter Catechism" drawn up two hundred and fifty years ago by the Westminster Assembly of Divines. Yesterday was celebrated the 250th anniversary of the day, 25th November, 1647, on which the House of Commons ordered 600 copies of the Catechism to be printed. In literary commemoration of the event a book has now been published giving a photographic facsimile of the document as then printed, with an historical introduction and bibliography by Mr. Carruthers, himself a prominent member of the Presbyterian Church in England.

The London correspondent of our evening contemporary says:—

It may be that the Colonial Office (notwithstanding the Kew people having decidedly said they saw no necessity for sending any one from England) have decided to act; it may be that a wire has come from Sir West Ridgeway upon which the Colonial Office people have promptly acted; or it may be that Messrs. Dickenson and Martin Pirie have secured sufficient support to their efforts to obtain £800 guaranteed by those interested in cocoa cultivation, and have closed arrangements with Mr. Carruthers and sent him off to catch the season. Mr. Leake, as Secretary of Ceylon Association in London, sent a circular to the leading cocoa proprietors here giving the facts up to date, and asking for adhesion to the above guarantee, but the replies were not of that nature that would enable Mr. Dickenson to act. But Mr. Dickenson has put his back into this business and deserves the greatest credit for all he has done. If his efforts have moved the various firms and individuals, armed as he was with the subscriptions of himself and Mr. Pirie, and, moving quicker than Government action moves, if he has carried his point and despatched Mr. Carruthers, he doubly deserves credit. I may mention that Professor Marshall Ward named a Mr. John Parkin, a demonstrator under him, but not more than two or three and twenty for the post. Mr. Carruthers is 30. His father, now retired, was many years at the Natural History Museum at South Kensington and is now Chemist to the Royal Agricultural Society. He has been, I hear, very strongly recommended for the Ceylon

post by his father's successor, Mr. Murray, under whom he has been working.

I have just heard that Mr. Dickenson has himself engaged Mr. J. B. Carruthers, and they have left today *via* Brindisi.

 THE CACAO DISEASE AND A SPECIAL CRYPTOGRAMIST.

We give Mr. J. Carruthers a hearty welcome to the island, and trust that his mission may result in lasting benefit to our cacao industry and in credit to himself. The name of his honoured father as well as his own have long been familiar to us, and from what we have heard of Mr. Carruthers' ability and past investigations—especially as to a disease affecting larch trees—we are very hopeful that practical good is likely to result from his visit to Ceylon. We feel sure he may depend on the hearty co-operation of Mr. Willis, Director of the Botanic Gardens, and of Mr. E. E. Green, Honorary Entomologist, as well as of the several planters in the island who have paid attention to the pest which has injured, and still troubles, their cacao fields. While admiring and giving special credit to the enterprise of the private proprietors—represented by Mr. Dickenson—who have brought out the Cryptogamist, we trust that the way will be made plain for an official engagement for Mr. Carruthers, so that he may be able to study the cacao disease not on one group of estates, in a single district; but wherever it is found, and so furnish an exhaustive Report and, let us hope, suggest a sufficient remedy. If it be true that Mr. Carruthers is the bearer of a letter from Lord Selborne, Under-Secretary of State to the Governor, we may feel hopeful that His Excellency will agree to make the visit, inspection and Report, more or less an official one, arranging that the three experts—Messrs. Willis Carruthers and Green—should, as far as possible, co-operate to the desired end, namely the overcoming of this cacao pest.

 GEM-MINING IN CEYLON.

WE call attention to a specially interesting letter from Mr. W. S. Lockhart, Managing Director of the Ceylon Prospecting Syndicate, Limited, which is about to commence active operations in Ceylon. Mr. Goldie and "the plant" may, by this time, be on the way, and Mr. Lockhart himself is likely to follow ere long. We are clearly on the eve of important developments in connection with this department of industry in the island, and about this we shall have more to say in another issue.

THE EXPERIMENT OF IMPORTING ORANGE from Australia in ordinary cases without refrigerating *en route*, has not been a grand success, judging from the out-turn of the fruit ex—"Lusitania," which must have been disappointing to shippers. Not a single case out of 1,157 catalogued was sound, and many lots contained so much waste that two boxes were required to make one sound when re-packed. Prices ranged from 5s to 17s; but it must be said that the fruit was delicious, and sure to find favour if shipments can be made in better condition.—*Grocers' Journal*, Nov. 13.

PLANTING NOTES ON THE WEST INDIES.

(From Report of West Indies' Commission.)

ST. VINCENT.

"At St. Vincent, coffee and spices are being grown. The value of the spices, chiefly nutmegs and mace, exported in 1895, was £1,812.

"In the development of these and other industries (including that of sugar), valuable services have been rendered to the island by the botanic station established in the neighbourhood of Kingston. The plants distributed have included 34,335 Arabian coffee, 3,164 of Liberian coffee, 5,343 cacao, 1,183 nutmeg, 2,390 new and improved sugarcanes, and 1,108 limes. The total plants distributed have amounted to 53,224. Large stocks of plants are still available for distribution. The Curator visits various parts of the island whenever his duties allow, and gives assistance to all engaged in agricultural pursuits. *Bulletins* with agricultural information are issued, and gardeners are trained in horticultural methods. The present curator, Mr. Henry Powell, is devoted to his duties, and his services are widely appreciated amongst all classes of the community. If the stringent measures of economy necessitated by the poverty of the colony are carried out, it is feared the usefulness of the station will be destroyed." *Report of West Indies' Commission.*

DOMINICA.

"The botanic station at Dominica was started in 1890, in a charming spot immediately behind the town of Roseau. Mr. C. A. Barber, late Superintendent of Agriculture in the Leeward Islands, states in a recent report:—"The founding of the botanic station in Dominica will probably, in future years, be referred to as one of the greatest strides in the progress of that island during the present period." There are large nurseries of economic plants and experimental plots for Cacao Coffee, Kola Rubber trees, spices, and fibre-plants. The station, which may be regarded as one of the most successful in the West Indies, has distributed 165,000 economic plants during the last six years, or an average of 29,000 per annum. The present curator, Mr. Joseph Jones, is described as having rendered 'great services universally acknowledged by the planters of the island.' The cost of the station in 1896 was £400, while the net receipts from the sale of plants were £99. It is proposed in the 'Additional Note' at the end of this report, to extend the work of this station, employ agricultural instructors, and establish an industrial school in connection with it." *Report of West Indies' Commission.*

MONTSERRAT.

"A botanic station, with a gardener in charge, was started at Montserrat in 1890, on a small plot of land to the South-west of the town of Plymouth. The space available was utilised for the cultivation of a selected number of economic plants: large numbers of these were raised and distributed during the last six years. Amongst them were 8,000 plants of Blue mountain coffee from Jamaica, 1,800 cacao, 2,000 nutmeg, pine-apple suckers, grape vines, 800 suckers of the Jamaica banana, Liberian coffee, kola, &c. The gardener also gave information in regard to the cultivation and treatment of new plants. The principal recipients were estate proprietors, and not small cultivators. The latter had evidently not been induced to start new cultivations, as, owing to the absence of shipping facilities, there was no prospect of being able to find a market for the produce. Owing to the straitened circumstances of the island, the botanic station has now been abolished, and the services of the gardener diverted to other duties. The work done at this station, with the limited means at its command, was of a distinctly promising character. It was the only organisation existing in the island for improving and extending the cultivation of industrial plants, and its abolition destroyed the hope of immediately benefiting the agricultural interests of the island."—*Gardeners' Chronicle*, Nov. 20.

PLANTING NOTES.

"LADY BIRDS."—We are pleased to see that the Nilgiri Planters' Association has not lost its interest in the proposal to introduce the scale-eating beetles from Queensland. At a recent meeting, the Association offered to bear half the cost of "Mr. Newport's" scheme for their introduction. Surely other Indian Associations will follow—not to speak of aid from Uva (?) and Java.

TEA, COFFEE AND CINCHONA IN INDIA.—Supplementary to his Annual Report, Mr. O'Connor, Director-General of Statistics for India, has issued three separate papers dealing with the above products and giving the latest official information as to area, production, persons employed, exports and consumption, prices. A great deal is mere approximation; for Mr. O'Connor dealing with all India, cannot as yet approach for accuracy the statistical returns we have, for so many years, compiled for Ceylon in our "Handbook and Directory." Still Mr. O'Connor gives us the best possible, and we shall deal with his information in an early issue.

CACAO CULTIVATION IN CENTRAL AMERICA.—We call attention to a chatty account of personal experiences in Nicaragua, and especially on an extensive cacao walk in that State, by Mr. K. W. Carter, reproduced on another page. Our cacao planters may not learn much that is new from it; but they will find it interesting to compare notes with Mr. Carter, and they may discover some reasons for reflection in what is said about shade, pruning and harvesting. It is news to us that British Honduras should have rich indigenous cacao of a fine description growing along the river banks in some districts. Mexico has been long known for its production of cacao—indeed the seeds were a substitute for currency in some districts in the time of Montezuma; and now that English capitalists are going there in connection with coffee, they may see it to their advantage to develop cacao as well. Meantime Mr. Carter's paper, contributed to *Chambers' Journal*, will repay perusal.

A NEW COTTON—Mr. H. D. Carroll, a young American traveller, a few years ago discovered a cotton plant in Central Africa, the quality and abundant growth of which—says *The Chamber of Commerce Journal* for November—so impressed him that he brought a quantity of the seed with him to the United States. Extended trials have been made with this seed in the State of Georgia, and if the reports thereon are only approximately true, it would appear, according to a New York journal, that a revolution in the cultivation of cotton is approaching. The first trials were made in the State of Georgia in the year 1895. Of the seed then sown fifty-seven cotton plants were obtained. The seed procured from these plants has multiplied to such an extent that it is intended to make extensive plantations in 1898. The cotton plants hitherto cultivated in the United States grow from three to six feet high. Whilst these plants, particularly during the first stage of their growth, require extraordinary care, the African plants require only very little attention. The new plants attain a height of twelve to fourteen feet, with numerous fruit capsules, which after bursting, show cotton wool of distinguished quality. This new plant is uncommonly strong in substance and presents by far more resistance to rains than the American one. The picking of the cotton also costs considerably less than that of the American. Whilst in Georgia two to three acres of land are required to produce 500 lb. of cotton; the African sort produces three times as much.

Correspondence

To the Editor.

COCHIN vs. CEYLON COCONUT OIL:
OIL MILLS AT BATTICALOA.

Batticaloa, Nov. 15.

SIR,—I have read the leader and correspondence in the *Observer* of the 10th inst.—Cochin vs. Ceylon oil—with great interest.

It might perhaps interest you to know, that large quantities of our best sun-dried copra are bought up by middlemen and shipped by native vessels to Cochin, to be made into "Cochin" oil. This refers mostly to copra made by European planters, who take greater pains to produce good, clean copra, than the villager does. I know also that a considerable amount of copra is shipped from Jaffna to Cochin. The mill-owners in Ceylon would turn out an oil, which would be quite as good as Cochin oil, if they would desist from making good clean copra with inferior stuff. On the estates I am in charge of, every hit of discoloured copra is carefully picked out and sold separately. Mill-owners, however, don't seem to care to pay a higher price for superior copra, and therefore most estate proprietors don't trouble much about the making of good, clean copra. Mr. Le Mesurier, I am glad to say, is putting up an oil mill here, and I also hear, that a similar establishment is likely to be started by another European. But I think, there will be no room for two mills, as even a small mill will consume at least 50 cwts. of copra per day.—Yours faithfully,

C. L.

COCHIN VS. CEYLON COCONUT OIL.

Jaffna, 16th Nov. 1897.

SIR,—You complained some time ago in your paper that the cause of the great difference in value of the Cochin coconut oil over the Ceylon article, is due to the superior whiteness of the Cochin copra, which, in its turn, is owing to the fact that, at Cochin, the copra is dried more carefully than in Ceylon. It may interest some of your readers,—merchants in particular—that, in the Jaffna district, owing to the dryness of the climate copra is dried by exposure to the sun, as soon as the nuts are plucked, and it is, I believe, equal in quality to the best Cochin article. The oil made of it ought, therefore, to obtain as good a price.—Yours truly,

B. L. MARTYN.

TEA CULTIVATION: SOME PRACTICAL QUESTIONS.

DEAR SIR,—With reference to the lengthy Enquiry being conducted in the columns of your paper I propose that you prepare and submit a few questions to the local scientific authorities such as the following:—

1. Is the average temperature of the soil lower on weedy land than on clean land?
2. Do the roots of the Tea bush become more clogged with moisture during the monsoon, on weedy land than on clean land?
3. Do weeds pick up the soluble nitrates more easily and rapidly than do the roots of the Tea bush?

I venture to suggest these questions as samples of queries that I think should be dealt with by our recognised authorities.—Yours faithfully,

INDIAN PLANTER.

GEM-MINING IN CEYLON.

Nov. 24th, 1897.

SIR,—I am glad to see by the editorial article (see page 379) that you point out the importance of the gem-mining industry to the trade of the island.

It is my belief, when accurate returns can be obtained, as the result of washing on a large scale, that the value of the gem-bearing deposits will be found to be far greater than has hitherto been conceived. Gems are never evenly distributed throughout the gravel beds where they occur and as a necessary consequence, washing on a small scale becomes a matter of chance. A rich spot may be hit on at once, or tons of barren gravel may be encountered and the work abandoned perhaps, as unproductive. On the other hand, washing on a large scale and without risk of loss either by theft or accident, renders the result a practical certainty, as the rich spots are sure to be reached from time to time and if the work is economically and regularly carried on, the "finding" over the whole will seldom be otherwise than highly satisfactory. If this view is correct, and the coming Geological Survey brings to light, as it no doubt will, districts rich in gems but hitherto lying unworked, the importance to the general trade of the island can hardly be estimated.

It is this consideration that has caused the Ceylon Prospecting Syndicate to be called into being and I am glad to see these views stated by one so familiar with the subject as yourself.

It is quite true that Mr. A. B. D. Goldie will shortly leave England for Ceylon, and the first large plant, which has now been built and thoroughly tested here, will follow him at once. A series of machines capable of dealing automatically with 60 tons or so of gravel per working day required care in manufacture, but the result has been satisfactory, and the seeming delay you refer to, will be found to be fully warranted when washing commences on the ground. This plant has been kept per work in London for the last month and has fulfilled all expectations with regard to it. We are sending you by this mail, copies of some of the technical journals which described it, as I feel sure they will interest you.—I remain, sir yours faithfully,

Wm. S. LOCKHART,

M. Inst. C.E., M. Inst. M.E. Managing Director, The Ceylon Prospecting Syndicate Ltd.

THE CEYLON GEMMING INDUSTRY.

BY A WORKER.

SIR,—As I had ten long years of Gemming life in the Southern Province, allow me a little space in your valuable columns, to throw some light on the gemming operations in Lanka, in a small as well as in a large scale.

The beginning (of course) was on a small scale, and owing to bad luck and thieving, the result was not a favorable one; after this with the help of Mr. C. P. Hayley of Galle, we got up a Syndicate and went Gemming on a large scale in Morowakorale. This would have been a paying concern if I had been supplied with proper machinery, and owing to this lack it turned out a failure. Thieving in the gemming operations is carried on in Ceylon, by the coolies in the small as well as in the large scale, not only where European management is employed, but even amongst natives themselves. At the washing time is not an easy job for them to steal, as there goes only the small gems and the watching is kept on keenly, but most of the gems are stolen at the time of the disintegration of the gravel, where a large gem cannot be hidden in the mud, but as in the gemming pits, there is always water, so the large gems left clear showing their beautiful colour, so if it happens that the snorvisor turns his eyes into a different direction, the gems will fly into the opposite way, the natives having many different tricks to let a gem disappear.

I do believe, that the new model of the Gem Separator will be good to a certain extent, but there are many other things to look into.

Generally gravels where gems are contained are not found on the surface, in many instances they must be dug several fathoms deep before they come over the gravels or (illama) as it is called by the native diggers, then the quantity of gravels secured by that pit, will be ten or twelve tons at most, then a fresh pit must be dug out, with this operation it will pass a month before you can secure a day's work for the Separator.

These given details are only preliminary. Now comes the trouble.

The people who go to dig or to desintegrate the gravels, are experienced diggers, the greatest villains and thieves in creation. After having broken the gravels they have to fill up the baskets and they are from hand to hand and are thrown out and put in a heap. And then they are filled up again and sent to the washing machine. After having passed so many hands, if a good gem had escaped detection from the coolies, you can say that it is a miracle. I am sure of this, because, I, and others employed under me, were watching very carefully, and many valuable gems were stolen by the coolies employed. Then it comes that, that the most of the gemming lands are paddy fields, where heavy loads cannot be taken across as the soil is swampy. Gemming operations in Ceylon are not an enterprise for Europeans as the facts have shown not long ago, that one after another, all the Gemming Companies have failed with heavy losses.

It is true that natives are gemming here and there; first of all they know all the tricks as to how a gem can be robbed; second, they have many trustworthy relatives to watch; third they have very little expenses to meet and in many instances they only feed the coolies. When they come across some gems, then they pay something to the coolies and the rest is pocketed by the Ralahamy or Loco Mahatmeya.

These are facts, and not made-up stories.

The Prospecting Company may turn out a success. To do so, first of all their agents must learn the native language; second, they must acquire experience, then it will give a good return to the Company; but I fear that by elapsing such a long time—which means money—it will be too late.

The Company will be successful at the very beginning if they engage a trustworthy and experienced man—not otherwise.

If I had not given up Gemming and come to Colombo, to reside here, and carry out my profession as a watch-maker, I would have been always hardup. Many who know me, not only in the Southern Province, but in many other parts of the island, will confirm that this is nothing else but the very truth.

I hope that the new Company will overcome all these difficulties and will be a successful one, but no one can assure me that they will not fail.

A. DE DOMINICO.

THE FIBRE OF CALOTROPIS

GIGANTEA:—WARA OR YERUKKALAI.

Vannarponne, Jaffna, Nov. 17.

SIR,—On reading in *Observer* of the 2nd November regarding *Calotropis gigantea*—Wara (Sinhalese), Yerukkalai (Tamil) cultivation and its use as a fibre plant, certain suggestions offered themselves to my mind which I wish to communicate to your journal and thereby make known to the planting community who are interested in its cultivation. Some six years ago Mr. F. A. Fairlie was deputed by the Director of a Manchester firm to see whether Wara cultivation could be carried on profitably in Ceylon. I then accompanied him through the Wannu district and we satisfied ourselves that the plant grows wild and that with proper management it will thrive well in the lowcountry.

Mr. Fairlie had to leave for England owing to urgent private affairs and nothing could be done further than to try the experiment on a small scale on "Temple Bar," Sir Græme Elphinstone's estate on Pallai, which was then under my management. The cotton produced on the estate was sent to England and was pronounced excellent. I have seen fishermen getting the fibre and making ropes out of it for their nets. Had even Sir Græme been in Ceylon at the time, I am sure the Wara cultivation would now be an accomplished fact and in full swing in the lowcountry.

The cotton obtained from the plant is of greater value than the fibre which must be considered as of secondary importance. It is of very fine quality and is much in demand and will find a ready market. I send you a sample of the cotton which you will find on inspection of the quality I describe.* It adds an increased interest in the cultivation, for it turns out to be doubly productive and large areas that lie undeveloped in the lowcountry can be turned to use if Government will grant reasonable concessions. The plant is never allowed by the natives to grow in gardens as it exhastes the soil and sucks up all manure. They uproot it whenever it is grown, for the winged seeds find their way to all parts of the land and plant themselves.

Your correspondent's suggestion to cultivate it on road sides and to supply the vacancies in tea will prove, in my humble opinion, detrimental to the staple industry of the island. Instead of proving an additional revenue I fear it will stunt the growth of tea plants and exhaust the soil.—I am, sir, your obedient servant,

M. CATHIRAVALO.

We find the following in the *Journal of the Imperial Institute* by this mail:—

THE FLOSS, OR "SILK-COTTON," OF *Calotropis Procera*. *Calotropis procera* is a shrub found in the drier parts of India, chiefly in the sub-Himalayan district, from the Indus to Jhelum; in Central India and the Deccan; and distributed to Persia and tropical Africa. *Calotropis gigantea*, a species only doubtfully distinct from *C. procera*, and which has the same vernacular names, is recorded as identical in its properties and uses. The sap yields a form of gntta-percha, and is also used as a tan and dye; a manna is said to exude from the plant; the bast fibre and floss from the seeds are well-known fibres; the root-bark and sap are medicinal; the wood is used for gunpowder charcoal; and various parts of the plant are employed for sacred, domestic and agricultural purposes.

These plants, *C. procera* and *C. gigantea*, yield two distinct fibres—(1) a silk cotton from the seeds, known commercially as "madr floss," and (2) a rich, white, bast fibre from the bark. The floss is soft, very white, and has a beautiful silky gloss; it is employed to some extent, like the Dutch "kapok," for stuffing pillows, but has generally been regarded as of too short staple to be spun, although as regards its possible use in this direction, a Lancashire spinner stated, at the time of the Colonial and Indian Exhibition of 1886, that he had overcome the difficulties, and was prepared to purchase any quantity. But, as the plant is only found wild, scattered over a wide area, the supply is limited and irregular. If it can be cultivated, there seems to be no reason why a regular supply should not find a market at a remunerative price, and, at the same time, by bestowal of attention to the cultivation and selection of seed, the character of the floss might be improved and its length of staple increased.

The attention of the Scientific Department of the Institute having been directed by the Government of India to the possible utility of this floss, it has been submitted to examination by Mr. C. F. Cross, Scientific Referee on Fibres to the Imperial Institute, and the following results have been obtained. The more important constants of the fibre, which has

* A sample sent to us indicates a very fine staple or floss.—En. T.A.

the chemical characteristics of lignocellulose, are as follows:—

Moisture	..	9.0	per cent.
Ash	..	3.0	" "
Hydrolysis	{	(Alkali, 1 " "	26.2 per cent. (loss).
		(Acid, 1 per cent. H ₂ S O ₄),	24.7 per cent. (loss).
Cellulose	..	69.8	per cent.
Furfural	..	19.5	" "

Mr. Cross states that this floss fibre is an extremely interesting chemical type containing as it does a very high and, in his experience, unique percentage of furfural. He is of opinion, however, that although use may be found for some applications of floss fibre, its somewhat unfavourable chemical characteristics are not likely to recommend it to the spinner, in view of the present low price of cotton.

The floss has also been submitted to the Expert Referee to the Institute on Fibres, who has reported that this floss was in considerable demand in the markets a few years ago for fancy textile purposes, but that, owing to the difficulties presented by the variations in the quality of the parcels supplied, and to the intermittent supply when requirements arose, the material has dropped out of use. The quality of the Indian growth has, so far, proved inferior to the product of Java, which is probably derived from *C. gigantea*, and of which small samples have occasionally been received from India. The present specimen was of fair colour, of rather short staple, somewhat tawny in character, and contained an excessive quantity of inferior, immature fibre and seed fragments. Many varieties of the floss in question have been dealt with, most of them from Calcutta, where it is sometimes called "akund cotton," which were usually inferior to the present sample. These samples were sold at as low a price as one penny per pound, and there was but little demand for them at the price. The trade in this floss might possibly be revived if a moderate and continuous supply could be guaranteed. If of good quality, it would realise prices ranging from 4d. to 5d. per pound (c. f. & i. terms). In packing for sale, the floss should be handled as little as possible, the pods and seeds being entirely removed and the floss left in its natural condition—unopened; any discoloured portions should be removed and forwarded separately. The bales received here from Java usually contain 80 to 90 pounds of floss tightly sewn in canvas, but not pressed.

"WARA" FIBRE: CALOTROPIS GIGANTEA.

Nov. 30.

DEAR SIR,—With reference to your planting correspondent's note, (see page 477), how can the cotton of this plant be said to have valuable medicinal qualities? Is it made into 'cellular' shirtings and 'war(r)anted' to prevent chills?

I sent home a sample of this fibre some ten years ago unnamed. It was prepared by hand, regardless of cost, and the brokers classed it as the finest Rhea, value, I think, £36 or £38 per ton. I do not remember the percentage of fibre from the weight of stems cut, but it was rather higher than that from Rhea stems obtained at the same time: the latter were grown, though, under shade. The *calotropis* would doubtless be improved by cultivation. The plant is very common over large tracts of our low-country, growing often in poor soil and springing up frequently in abandoned chena lands.

The medical profession, when they have leisure and inclination to examine this and other native drugs, may find "Wara" of some value: the milky juice is often used as an application in cases of rheumatism and as a blister for liver complaints and for coughs.

If the Director of the Royal Botanic Gardens would send home a bale of the silky floss obtained from the seed-pods, we should soon know whether this product was worth collection, but I fear he has no funds for experimental work of this kind.—Yours faithfully,

B

HOW TO ECONOMISE LABOUR ON ESTATES.

SIR,—It seems at first sight venturesome, if not absolutely reckless, for anyone to undertake to criticise the opinions of an Editor, and especially of one having practical knowledge of this subject as an estate proprietor. But there are many questions, in connection with the discussion which has recently taken place, which naturally hinge on the points that have been specially brought forward for debate, and it is to these that the writer more particularly invites attention. As with other Examination papers, there is a natural tendency to stray beyond the limits of the questions set: indeed to answer them all fully, with all their collateral issues, would involve the compilation of a Treatise on estate management. Many of the contributors have been very careful to avoid going beyond the bounds: some no doubt with a wish to be precise, other apparently because they felt they were on dangerous ground. With the country flooded with "Experienced" creepers who have paid their trainers' board expenses and premium for twelve or eighteen months, and are eager to drop the opprobrious title of creeper for that of assistant superintendent, it is hardly safe for any planter, unless he has special interest with his employers, to breathe a syllable which might be construed as a reflection on the existing state of affairs. He must agree with Pope, "Whatever is, is best!"

The circular issued by the Editor of the *Ceylon Observer* contained queries with reference especially to the labour supply on Tea plantations, but as many estates comprise, in addition to tea, considerable areas of coffee, cocoa, cardamoms, etc., it will be convenient to treat the questions as applying to all estates on which Tamil coolies are employed.

As regards the first question: *Wire Shoots*. The advantageous use of these may in some few cases perhaps depend on the situation of the coolies' lines. If the lines are near the factory and the estate a small one, a wire shoot for the transport of leaf might be of no advantage, but on very many estates there is no doubt that shoots might be erected and would effect a large saving in transport of leaf, grass and firewood. Anything that saves the labour force from extra work in the evenings is certainly worth consideration.

2. *Labour-saving appliances*.—There is room, as many contributors have shown, for more appliances in factories: some seem to be always muddled. Withered leaf, for instance, is often carried by coolies from the withering shed to the rollers, exposed to the outside air; in other cases it is carried downstairs instead of being passed through the floor into the roller's mouth. Able-bodied men, who might be employed at pruning, or sawing and splitting firewood are often to be seen in the factory doing work that would be better done by children.

For field works, the more extended use of single bullock carts, hand carts and porters' barrows, for transport of leaf, manure, grass etc., is very desirable. The objection to bullock carts on some places is that grass is required for the cattle, and the modern mania is to plant every yard of ground (except the Tennis court,) with tea, from the boundary right up to the bungalow doorstep. For this reason on many estates, no space is allowed to the coolies for vegetable gardens, and the Superintendent must live on condensed milk and feed his horse on straw as every ravine has been drained and cleared of grass.

3. *Tramways*.—There is little prospect of these being used except on large estates in the lower districts, and as long as coconut estate proprietors with their special facilities of level ground and large acreages, do not adopt them, it seems hardly possible that they would prove economical for Tea unless a large group of estates combined for their construction.

4 and 5, *Weeding*: 7, *Drainage*.—The majority of planters in favour of the present system of weeding appear to be actuated solely by the fear of losing their labour force, if any change were made. This

would, of course, be a sad result from efforts to "economise the existing labour supply;" but the question is a wide one, and some points in connection with it have been altogether unnoticed. We must all admit that with this question, as with many others, different methods may be necessary in different districts, but speaking generally, the following bases will be agreed upon (1) monthly weeding, instead of three-weekly, as giving less trouble to the superintendent, and (2) payment of R1.00 per acre as an average minimum. Fifteen or sixteen years ago, when the rupee rate was first introduced by a Colombo estate manager, the suggestion was met with howls of derision as an utter impossibility. And this was when coffee was the principal cultivation, nearly covering the ground with its horizontal growth! Varying rates were then in vogue, from R1.50 to 2.50, or more, per acre, but the weeding contracts were then, as now, looked on more as a means of drawing regular weekly supplies of rice than for making money.

First, as regards monthly weeding. This system was adopted naturally in the beginning as being most convenient, and it has many advantages when properly attended to. But the contractor is frequently left to his own devices: there is no proper supervision (on many estates, the weeding coolies do not even come to muster), and when the contract, through their bad work, illness or idleness, gets behindhand, it often happens, as the contractor has frequently shrewdly foreseen, that the superintendent is unable to lend him any labour, all checkroll coolies being required for ordinary words. Result: the field goes back and the rate of pay has to be increased for some months. Sunday weeding is sometimes resorted to, the hired coolies being paid in rice or cash. It is on occasions like these when, without supervision, work is disgracefully scamped, and more harm done to the field than most people realise. Growing weeds are covered up with dead leaves or soil scraped over them: holes are scratched a few inches deep and bushes of weeds "buried" with a handful of soil, only to be washed off with the next rain: weeds growing near timber-belts, precipices or jungle are thrown hastily into them where they quickly take root and become nurseries of seeds.

Secondly, as to rate of payment, most planters appear to be under the impression that when their weeding has been got down to a rupee per acre they have touched bottom: it is not safe to reduce the rate further as the Kanganani must be considered or rather his so-called Coast Advance Account. *This is the parasite which paralyses all estate work.* It is a remarkable fact that the gentleman (?) who invented the "tundu" system, which has been the cause of all our modern labour troubles, has never yet come forward to assert his right to a statue or an annuity. When Hindu mythology has room for a new god, the chetties perhaps may elevate him, but he will probably go to his grave "unwept, unhonoured and unhung." Some planters argue that the rupee rate is incapable of being reduced, because the contractors always lose money in the wet months. They miss two points: weeds grow much less in cold, rainy weather, and the average contractor is not fool enough to retain a losing business. Were it not for the awful amount of advances outstanding, the average cost of weeding even on the present system, might be very considerably reduced, but it is a work, which, merely because it is done by contract, too often receives but little attention from superintendents. Too much power is sometimes allowed to a head kanganani, the whole acreage of an estate being given him on contract. He will sublet the fields at perhaps half the rate paid him, and having the contract in his own name, he will keep their accounts, in a certain way, himself, and even where this mistake if not made, what a lot of room there is on most estates for more supervision. How often is the weeding of part of a field carried forward to the next month, and then repeated, instead of the contract being given to a better man; and how often is the weeders' use of mamoty and geraper winked at if not actually sanctioned on estates

supposed to be weeded entirely by hand? On how many estates are eoty-sacks issued to the weeders, or when issued actually used for bringing weeds to the roads? We sometimes go out of our way to divide the weeding contracts into small fields, so as to give each sub-kanganani one, at R10.00 or 12.00, though no single cooly, however conscientious (and these are scarce) can fairly earn so much in the average twenty days which they work in a month. So the small contract means either double payment or scamped work, the field if finished being done with the help of borrowed labour, often young children from the lines.

And what a waste of supervision (or loss of it) there is on the small contract! The kanganani's wife or niece will saunter out at 7 or 7.30 a.m. (even if she has attended muster) and begin weeding when the sun is well up. If the field is too far away to allow of her going back to breakfast at 11, she will work on diligently till 2 or 2.30, when it is time to collect firewood. On any average estate she will by this time have collected all the vegetable luxuries, called by the general name of "keeri," which her family may require for curry, so that she can get back to the line easily by four o'clock to attend to her household duties. And for this work, or rather occupation, she is paid about ten rupees per month, perhaps more, though five would cover its actual value. If we were to work five or six of these small contracts together, with the same identical coolies to weed them, for a month, and an independent kanganani to look after them, paid by results, what a shock it would give us! The head kanganani would ask for his "tundu," or a further advance of R500!

There are two sides to every question, so having looked at this from the employer's point of view, let us now take a glance at it on behalf of the cooly. Many estates are not kept in such good order as they should be. Roads and drains are often scandalously neglected, through a mistaken policy of economy or through labour being scarce, and though many people do not seem to be aware of it this adds considerably to the growth of weeds. Some fields are from aspect, soil and situation more favourable to the growth of weeds than others: some have weedy, ravines and precipices with perennial supplies of seeds ripening in them, and jungle boundaries are a perpetual curse if weeds have been thrown into them. Other fields may be perfectly sheltered and shaded, but are often given out at the same rate as the most difficult contracts. Bad drainage means not only wash but weeds also. The least accessible fields are often the most in need of additional drainage, while boundary drains even on many old estates have never yet been cut. Some fields are very badly roaded and without weed pits have no convenient places for depositing the weeds. So much for the cooly.

A wider knowledge of the first principles of agriculture would be of use to many of us. How few planters apparently practically understand the objects and effects of draining, and the results of planting shade trees. With a more extensive acquaintance with what is really only elementary gardening, we should not so often see the cutting of new drains postponed indefinitely, the clearing out of drains neglected for months together or exposed fields of tea left without shade trees being planted throughout. The general planting of grevilleas and other shade trees, as some contributors have advocated, would, with regular attention to drains instead of the present studious neglect, enable us to reduce our weeding expenditure by nearly 50 per cent.

Though "selected weeding" in fields devoid of shade, very considerably reduces the wash caused by heavy rains, its adoption cannot fairly be made an excuse for lowering rates at first, as the mosses and small ferns require occasional regulation and removal from the base of the stems. The writer was able some years ago to reduce his weeding rates from R1.25 and R1.50 per acre to 75 cents, and the contractors made larger profits than under the old system. But the reduction was facilitated rather by extra attention to drains and to the weeding coolies, and also to the planting of cuscus and lemon-grass

on rocky hedges to prevent wash. The estate was a steep one and W. J. (No. XVIII) will perhaps, be interested to learn that the mosses grew luxuriantly even below 1,000 feet elevation.

As regards cuscus grass, another contributor No. (XXXII) complains that it suffers often from fungus, scale insect, and black bug. This is the case only when it has been carelessly planted; often with all its rootlets chopped off the plant is *shoved* into a small hole in perhaps stiff clay, without any pretence even of forking up the soil. It is a grass: it *must* grow! Cuscus or lemo-grass is much to be preferred to hedges of tea as a means of stopping wash or preventing drains being choked, but it should be cut regularly, and if not required for cattle bedding, be spread on the ground and, if possible, forked in.

INSPECTOR.

MR. T. N. CHRISTIE AND CEYLON
TEA IN RUSSIA.

Kandy, 4th Dec.

SIR,—I enclose copy of a letter from Mr. Christie, acknowledging vote of thanks passed at a recent general meeting. I also send extract of a private letter from Mr. Christie as giving interesting information regarding his visit to Russia.—I am, dear sir, your obedient servant,

A. PHILIP,

The Hon. Secy., Planters' Association of Ceylon.

(Extract of a Letter from Mr. Thos. North Christie, dated 11th Nov. 1897.)

I am leaving London about the 25th for Russia. I have already obtained a good deal of information, and am well provided with letters of introduction for St. Petersburg, Moscow, and Odessa, and the Colonial Office people are providing me with letters of official commendation to the British Consuls. I hope to be able to report by the 1st January.

Drumblair House, Forgue, by Huntly, N.B.,
11th November, 1897.

The Secretary, Planters' Association of Ceylon.

Dear Sir,—I have to acknowledge your letter of the 27th ultimo, giving cover to copy of a Resolution passed by your Association. I much appreciate the kindly manner in which my services, as M. L. C., are referred to, and I beg to thank the Association therefore.—I am, dear sir, yours faithfully,
(Signed), THOS. NORTH CHRISTIE.

RICE FROM SOUTH INDIA.

Glenomera, Talawakelle, Dec. 4.

SIR,—I am in receipt of a letter from Capt. Shelley, General Manager, South Indian Railway, from which I quote as follows. Date 29th ult. : —“The through rates we quote for a bag of rice not exceeding 190 lb. in weight include Indian export and Colombo import duties, Colombo harbour dues, and all other incidental charges. Provided the bags of rice do not exceed 190 lb. in weight, our rates cover *everything* after receipt at one of our stations to arrival at station on the Ceylon Government Railway. It may interest you to know the actual details of the harbour and Customs charges included in the through rates which are as under :—

	R.	A.	P.
Pier dues at Tuticorin	..	0	0 2
Export Customs duty at Tuticorin	..	0	6 9
Harbour dues at Colombo	..	0	1 3½
Import duty at Colombo	..	0	13 5
Landing at Colombo and loading on carts	0	1	1½

Total R1 6 9
(say R1 42½ cts.)

Captain Shelley suggests that the writer should pay a personal visit to the Tanjore district, when he has little doubt that business might be done with a great saving of time

and money. For the information of the public he states that cheap excursion tickets for the Christmas holidays between Colombo and Madras are to be issued by his Company. The cost of S.I.R. time-table (to be procured from the Company at Trichinopoly) is 2 annas or 12½ cents Ceylon currency.

So far Captain Shelley, to whom our thanks are due for this information. It will be apparent that the cost of transport of rice by this route compares very favourably with that of sea-borne rice as estimated by Mr James Gibson, whose large experience of the rice-trade, places his figures above suspicion.

Taking the 190 lb. bag of rice at 2¼ bushels nett (it really amounts to a little more) it will be seen that the rate of transport to Bandarawella amounts to R5.02 cents per bag or R1.82½ cents per bushel, as against Mr James Gibson's estimate of R1.97—delivery charges by sea and Ceylon Government Railway at the same spot, a saving of 14½ cents per bushel.

It is therefore clear that South Indian rice can compete with sea-borne rice in the matter of transport rates, and I am informed that in January, 1896, the cost price of rice at Tanjore was slightly under R2 per bushel. This rice might have been placed at Bandarawella at R3.82½ per bushel as against R3.95 for Calcutta rice purchased at R2. I am also informed that the rice in question was Mootoo Samba and Kalunda, which are superior in quality to the average Soolye rice given to coolies.

Under these circumstances it might be advisable for some one to go from this side to Tanjore about Christmas time and purchase a trial shipment of rice, and I shall be happy to join a small syndicate of not less than ten members to purchase 1,000 or more bushels of rice at a cost not exceeding the current Colombo rate. I regret that I cannot spare the time to go myself, but there will be little difficulty in finding a more efficient substitute.

I must apologise for trespassing so far on your space, and the patience of your readers, and remain, yours faithfully,

JAMES RYAN.

AN INSECT ENEMY OF TEA.

Dolasbage, Dec. 8.

DEAR SIR,—Under separate cover I send portions of tea branches killed by a borer. You will see the borer (resembling a weevil) eggs &c., in and on the branches. You can also see the perforations on the outside of the branches, through which the borer enters. I have referred to a work on tea pests, but nothing resembling this is shewn.—Yours faithfully,

WALTER R. TRINGHAM.

[Our reference to the Honorary Entomologist has brought the following :—

“The insect is a scolytid beetle,—by name *Xyleborus formicatus*, *Eichhoff*.” It was described and figured in the ‘Indian Museum Notes’ Vol. IV, No. 2 page 37, from specimens sent by me in 1895, which specimens were obtained from the same district viz., from Craighead Estate, Nawalapitiya. The article from the ‘Indian Museum Notes’ was copied, (with description of this particular pest in full) into the *Tropical Agriculturist*, September 1897, Vol. XVII page 207.”

Our correspondent has no doubt his T.A. by him to refer to—it ought to be filed in every Tea Factory in Ceylon; and if Mr. Tringham, requires further information and advice, he should consult Mr. E. E. Green, the Hony. Government Entomologist.—Ed. T.A.]

TEA PLANTATIONS: WATER-HOLES AND FORKING.

Dec. 11.

DEAR SIR,—When reading over the replies to your query No. 7, I note that "S. E.," "N. H." and perhaps others advocate the old system of water holes! Surely they have little or no experience of the result?

In the old coffee days we cut trenches, say three feet long, one foot broad and 15 inches deep, on the face of a hill field in Dolosbage.

There came a heavy downpour of rain, after a few days' light rain: here and there, one of the holes became full and commenced to run over; this caused the next one below it to do the same with increased volume; each succeeding hole added volume and force to the rush of water. Hundreds of tons of soil were washed away, down into the drains, roads and ravines. The lines in that field ran as perpendicular as the hill would permit; consequently the scour was chiefly down between the lines of trees, but in many places the trees were left on stilts!

I give this one particularly bad instance. But I can point out hundreds of acres of land now in tea (formerly in coffee when the holes were cut) and the ledges still remain (2 feet square or so) showing what was the bottom of the old holes; there being the original hill slope between these ledges. All the soil excavated was soon washed away, once the holes began to fill and became shallow enough to run over in wet weather.

Another writer states that "forking would cause too much wash."

Forking causes no wash if properly done. But forking and draining may have and do have ill effects on free soil in districts subject to long droughts. For that reason I have heard of drains being filled in again.

Forking in stiff soil, with tram forks, driving the fork as deep as it can go (15 inches to 18 inches) into the ground: then merely shaking the fork sufficient to loosen the soil between it and the spot it had last been inserted has a wonderful effect. The fork must be drawn out carefully, not pricked, no turning over of the soil. The surface remains as it was excepting that the humus and loose surface soil slips into the cracks, and hard lumps crumble as you walk upon them.

In very stiff clayey soil a light sprinkling of unslaked lime before the forking has a beneficial effect.

The foregoing is the result of many years' practice.—Yours faithfully, VETERAN.

THE MODERATE PRUNING OF TEA ADVOCATED.

Dec. 12, 1897.

DEAR SIR,—That you did a world of good by publishing those 84 letters on "Plucking, Pruning and Cultivation of Tea," there cannot be a doubt, and your reviews on the same were fair and pertinent. I am not coming forward with a "Review of Reviews," but if you will allow me a little space, would like to revert to one of the topics discussed, viz., pruning or overpruning. Of the 84 writers, 56 were against the hacking down system, 22 alluded to the matter but slightly, three favoured severe cutting down, and two favoured it apologetically. Of the 56, some went the length of saying the tea made after excessive cutting down could not regain its former excellence in less than twelve months. Others men-

tioned periods of six to ten months. Different elevations, of course, regulate that considerably. But what about the cut down bushes? In some cases hacked in almost to the collar. I maintain that they are permanently damaged. The property deteriorated for all time. In such cases nature makes an effort, especially when the tea is not very old to make up her loss, a cluster of wiry shoots springs up close together, because the breadth has been cut off. The wood is slender and weakly, the leaf small, the coolies cannot bring in their former task. The work is thus costlier. The tea made has neither colour, flavour, nor strength. Bad reports come from London. The directors, would never think of attributing blame to their V. As. who directed the cutting down. The superintendent must be made the scapegoat. I am not setting up as the superintendent's advocate however; but in such cases, I pity shareholders whose properties have been so reduced in value, and dividends curtailed, they all the time ignorant of this, as one great cause. That the system is fast running itself out is clearly proved by the great majority of those 84 experienced writers; but there is still to be seen, sadly mutilated fields, low narrow rows, instead of the once strong spreading bushes, the coolies stooping to pluck as if gathering strawberries, and the half-exhausted bushes looking as if in need of pruning again in less than nine months.—Yours faithfully,

"MODERATION."

PAPAYA JUICE.

Sumatra, O.K., Nov. 1897.

DEAR SIR,—I would be obliged if I could get any information regarding the mode of packing the dried juice of the Papaya tree and also the address of a proper person in London to give a report thereon. Perhaps some of your obliging readers will help.

Also the quantity of fibre obtainable from the pineapple in proportion to weight of leaf, or number of plants of the proper kind for fibre.

SUMATRA O.K.

[Our correspondent makes rather a wide order. In back numbers of the *Tropical Agriculturist* there is much information regarding Papaya juice and Pineapple fibre, and Mr. Thos. Christy, 25 Lime Street, London, E.C., will, we feel sure, be ready to report on any samples sent to him.—Ed. T.A.]

MR. POPOFF'S TEA GARDEN AT BATOUM.

INTERESTING LETTER FROM MR. VALENTINE WEBSTER.

Moscow, Nov. 6.

DEAR SIR,—I arrived from St. Petersburg on the 2nd, and leave for Odessa on the 9th. I had a letter of introduction to Messrs. K. & C. Popoff, who own the largest tea packet business in Russia. I met Mr. Popoff, the founder of the firm and proprietor of the tea garden in the Caucasus mountains, today. The garden has nothing to do with the firm of K. & C. Popoff, of which he is chief.

Mr. Popoff has given me a letter to the superintendent of his garden, which is ten miles from Batoum, in the south end of the Caucasus mountains. He has many strange ideas, as will be seen from the following facts:—He has already planted 160,000 trees, mostly from China seed, with a few small patches of Assam, Darjeeling, Ceylon and Java. In the winter they have down to 10 degrees of frost; and in the summer it is very hot. Labour is 1s. 6d. per day and a free house! Mr. Popoff does not believe in machine-made teas and cannot understand why in Ceylon and in India with our cheap labour, we will spoil our teas with machinery, when it can be so well done by hand!! He says hand-rolled teas are far superior: the difference

is as great as a tune played by a good orchestra, and the same tune by a German organ! Mr. Popoff does not believe in the Ceylon and Indian methods: those of the Chinese planter are far superior. At the same time he was much pleased with my pamphlet, "How tea is grown and prepared in Ceylon," and asked if he might keep one.

I sail from "Odessa," on the 13th, and arrive at Batoum on the 17th, and at Mr. Popoff's garden on the 18th instant.

Mr. Popoff is giving me a sample of tea made on his garden. This will be very interesting.

Few can have any idea how much behind the times this great city is: even the houses in the streets are not numbered. Cold weather has set in, and I shall be glad when I see the last of it and of Russia. I hope to be in Colombo the first week in January.—Yours, &c.,
R. V. WEBSTER.

—Local "Times."]

THE "WARA"

I have just got a tin of "Wara" seed from the Coast and intend giving it a trial. I send you by same post a little sample of the "Wara" cotton, which is said to have very valuable medicinal properties. It looks very fine.—*Planting Cor.*

PLANTING NOTES.

TEA CULTIVATION AND PREVENTION OF WASH.—We can only now direct the attention of Estate Managers and Proprietors to the very suggestive letter, which Mr. E. E. Green sends us on the subject started in our columns by a veteran planter.

OIL ENGINES.—With the rebate on Kerosine oil coming into force from the beginning of the year, there ought to be a considerable run on "Oil" Engines of the type that has already given satisfaction. It was the nonsuccess of "Priestman's" in Kandapolla, we think some years ago, that gave a bad name for the time and left an unfavourable impression on our mind as to Oil Engines. But there have been evidently great improvements in other inventions, as may be seen from what is stated by Messrs. Walker Sons & Co., Ltd. in reference to the "Campbell Oil Engine." One of these—9 horse-power—we learn, is to be erected in Colombo shortly to drive rice-hulling machinery and we have no doubt it will be an object of interest to very many in search of a reliable, simple and cheap motor.

TRADE ALLOWANCES ON TEA.—"Udapussellawa" writes to a contemporary:—"One pound per package, on full chests amounts to say 1 per cent, each chest containing roughly 109 lb. tea, but 1 lb. a package, on half-chests amounts to 2 per cent. This is most unfair for several reasons. Packing in half-chests is more expensive per pound than in full chests. Half-chests are more suitable for grocers, and therefore, more attractive for buyers. Several producers are obliged to pack in half-chests, owing to the distance they have to send their tea on coolies' heads to the nearest cart road. Thus in fairness half-chests, should be taxed at a lower rate in London, as they cost more in proportion than full chests, at any rate they should not be taxed by the buyer at a *higher* rate than full chests, which is being done at present."—We think this proposal a very reasonable one, and one that ought to be taken up by the Tea Committee of the Ceylon Association in London.

THE "CEYLON FORESTER," a quarterly magazine on Forestry, Natural History and Shikar. Edited by H. P. C. Armitage, Assistant Conservator of Forests, Colombo. Contents for the 3rd quarter, 1897, are as follows:—Ourselves; On Ceylon Ferns; The Girdling of Trees; A Tour in the Western and Sabaragamuwa Provinces; Feather Shooting in Ceylon; Reviews; Administration Report of the Royal Botanic Gardens, 1896; Practical Hints of Forest Zoology; Collection of "Dorana Tel" or Bambarabotuwa; More about Raobab Trees; Cobrain Stray Notes; Tit Bits on Forestry; Notes on Ceylon Birds.

GEMMING IN CEYLON.—Mr. W. S. Lockhart and Mr. Goldie cannot fail to be interested if not edified by the letter which Mr. A. De Dominico—the well-known Colombo watchmaker—sends us and which is reproduced on page 471. Allowance must be made for the use of what is, practically, a foreign language to the writer and then it will be found that the letter gives some practical information. It is quite possible that the Prospecting Company may devise some method of excavating by machinery to get over one difficulty pointed out by our correspondent. But if not, the risks of loss cannot be nearly so great with a Separator as under the old system. Still there are difficulties before the new experiment; but we may hope to see them overcome by the combined ingenuity of Messrs. Lockhart and Goldie.

RAPID GROWTH OF THE CEYLON TEA TRADE: A RECORD!—*Pearson's Weekly* of Nov. 20, in its column for queries and replies asks "State which is the Most Striking Instance of the Rapid Growth of a "Trade." The reply is as follows:—

Taking the word "trade" in its widest sense, the answer would be the trade of Ceylon. In 1883 Ceylon produced only one million pounds of tea. In five years this grew to about twenty millions. The reduction of the duty in 1890 to fourpence led to an enormous increase in consumption of tea generally, and this has, of course, greatly stimulated the Ceylon trade. Five years later the output had risen to the enormous figure of 67,718,371 pounds. The history of trade affords no parallel to this development. Of course the cycle industry is a case in point, but that is rather the development of a branch of the long-established engineering trade than the creation and development of a new industry. Given this limitation, however, the growth of the cycle trade would make a good second to the development of tea industry of Ceylon.

Well done the first of Crown Colonies!

JAMAICA RAMIE.—Mr. Leon Bernstein, Managing Director of the Jamaica Fibre Company, Limited, having forwarded to the Imperial Institute, London, two samples of Ramie filasse, prepared here by the Macdonald-Boyle process—says the Journal of the Jamaica Agricultural Society—has received a most encouraging report from Sir F. A. Abel, Hon. Secretary and General Director of the Institute. The best of the samples was declared by Mr. E. E. Collyer, the Expert to whom they were referred, to be "very good quality degummed, excellent in colour, and yielding a large percentage of top." He adds: "Supplies represented by it would probably realize £60 per ton and upwards here, if sufficient quantities can be guaranteed." The other specimen, derived from very young stems, though not so satisfactory, was estimated to be worth £45 to £50 per ton. An extensive firm of Produce Brokers, having seen the samples, have written offering to take a quantity of filasse. A good market for the fibre thus seems assured, and we trust soon to hear that the Company has started planting operations. Samples are a poor test after all: one would like to see a quantity turned out and to learn the cost.

THAT RIDICULOUS "COCOANUT."

THE EDITOR OF THE "DAILY CHRONICLE."

Sir;—In the "good long taste" you have today given your readers of Mr. Allen Upward's poetic quality, there is one "thing" described by that gentleman which can scarcely be characterised as "common." You quote Mr. Upward as referring to the A. B. C. shops.

"Whose air the rich aroma fills
That from the cocoa palm distills."

For Mr. Upward's benefit I may state (1) that the odour of the toddy distilled by the coco-palm is the very opposite of a "rich aroma;" and (2) that cocoa is a product of the cacao-tree (*Theobroma cacao*). But so long as the erroneous spelling cocoanut (due to a blunder of the printers of Johnson's Dictionary) continues to mislead the ignorant, so long must we expect such absurdities as that perpetrated by Mr. Upward.—Yours faithfully,
DONALD FERGUSON.

Croydon, Nov. 6.

[The strange part is that botanists beginning with Key, keep to the "Cocoanut" form of spelling of *cocos nucifera*. Emerson Tennent set the example of "cocoanut" in his Ceylon books, and we have adhered to it for many years in all our publications.—ED. T. A.]

THE CHINA TEA TRADE.

We reprint in our *Tropical Agriculturist* from a Hongkong paper, information which ought at once to edify and amuse Ceylon tea planters. The latter are already aware of the steps taken by a Syndicate through a regularly organised Factory to arrange for the preparation by machinery of all teas grown in the extensive tea districts around Foochow, and of the high testimonials put forward as to the value of "machine-made" teas. Now, however, the tables are turned. The Dutch Minister at Pekin, acting on behalf of Amsterdam tea importers—of all people in the world—has protested against the fine delicate flavour of China teas being destroyed by European machines,—lost in the many processes incidental to the Foochow factory,—so that if the new scheme is persisted in, it will be impossible to procure the highly-prized teas prepared by the old Chinese methods. This protest has been taken up cordially by the Chinese authorities and the resulting Proclamation to the Provincial and District Mandarins may, quite possibly, have the effect of keeping back a great deal of the tea-leaf expected at the Foochow Factory.

Meantime, the export of China teas this season seems to show a decided decrease all round, while that of Japan teas to the United States shews a comparative increase!

IMPORTS OF TEA SEED.

THE imports of tea seed at Colombo this season have been rather notable, considering the feeling that extension of cultivation had received a check through adverse exchange and low prices. The Customs returns are as follows:—

	British India.
September	— Nil.
October	Cases 137
November	" 4,285
Up to 9th December ..	" 2,434
	Cases 6,856

Each case of tea seed may be taken to represent a maund of 84 lb. with from 20,000 to 30,000 seed, and counting 15,000 plants as resulting

from each maund, and 3,000 to 4,000 plants as covering an acre, according to distance the planted,—total imports should represent from 27,000 to 34,000 additional acres to be planted with tea!

SEYCHELLES VANILLA.

From official information supplied by the Colonial Office we learn that the vanilla-crop of 1896 in the Seychelles was the largest ever produced in those islands, viz., 63,000 lb. As the prices ruled higher than for many years past, the planters have done so well by this crop that they have very greatly extended their plantations. Moreover, the country is now being opened up by new roads, and many thousands of acres of virgin soil suited to vanilla growing, but now uncultivated, will shortly be made available. In the district of the Mare aux Cochons alone there are about 5,000 acres of this kind. The cultivation of vanilla in the Seychelles dates back about 20 years, but it is only now beginning to be understood. Formerly the vines were trained on artificial supports, by the Mexican system of allowing the vines to grow wild has of late years almost superseded the old plan. It is said that nothing pays better than vanilla-growing. The average cost of production, including dry and getting ready for the local market in the Seychelles, is only R3 per lb. whereas the local sale price in 1896 averaged from R8 to R16 per lb. And as the average yield of dried beans per acre is 200 lb. it follows that there are few crops (certainly not sugar, the staple product of the Seychelles) which give the grower a better return. Most of the land in Seychelles is in the hand of private owners, but may be bought at from R100 to R200 the acre for ready money. There is also some land belonging to the Government well adapted for vanilla cultivation, which can be leased for periods varying from 9 to 21 years. In 1882 the yield of vanilla in the Seychelles was only 2,400 lb.—*Chemist and Druggist*, Nov. 27.

CALOTROPIS PROCERA AND GIGANTEA

"WARA" FIBRE CONDEMNED.

In the "Forester" for September it is stated that an expert is coming to experiment with the above-named plants, and G.M.R. asks for information or opinion on certain points. He probably knows as much as anybody about *C. procera*. To begin with a trifle, it is a very mild statement that the fibre has been known for 20 years or more. A fibre that is used to the exclusion of all others for every important purpose, except clothing and large ropes, for which it is not common enough, must have been known to the people of Alexander's time, if not of Noah's, and the poor young merchant adventurer who left his bones at Tatta sometime about the middle ages had no doubt a practical acquaintance with it as we have. As to quality, it is stated that the fibres of both species are equally good. That is a statement that I have hitherto taken for truth, and have now to suffer certain qualms of conscience, because I knew the fibre of *C. gigantea* to be neglected in the Peccan, where it is common, and never suspected the possible reason, viz., its uselessness. However that may be, I found the fibre of *C. gigantea* quite useless in the Saharanpur District in the month of February. We have thus to find out when and where this species is worth gathering. That being the case it is little consolation to be told that this fibre gives a greater proportionate yield. As to cultivation, I considered the matter some twenty years ago, and came to the conclusion that it could not pay, and think so still, principally on the ground that the plant is of a straggling light demanding habit and could probably not be grown dense enough to give any considerable yield, but I made no experiments on the point, and that is the only reliable source of information.—F. GLEADOW,
—*Indian Forester for November*.

THE ANGLO-CYLON ESTATES DIVIDEND.

(To the Editor of the *Financial News*.)

SUGAR-PLANTING IN MAURITIUS: A NEW VIEW OF FREE TRADE PRINCIPLES.

Sir,—A short time ago a feeling appeared to exist amongst those most interested in sugar planting in Mauritius, that as soon as the cable was repaired the principal conclusions arrived at by the Royal Commission which went to collect statistics of the sugar industry in the West Indies would be cabled to most parts of the world; for a rumour had obtained credence that its report would be published about the end of July. Up to the present time, however, nothing has been communicated, and the news received by the last mail is in no way assuring that we shall be placed in presence of the Commissioners' views at an early date. Mr. Chamberlain has stated that he declined to put any pressure on the members to hasten the issue, as he has no wish to hurry them in a matter of so great importance. The suspense is irritating to many proprietors, who feel that a sword is hanging over their heads, and are anxious to know the worst. We think that these should take heart at Mr. Chamberlain's change of front. At one time the Secretary of State for the Colonies appeared to think that the bounty question was one in which the Home Government was not called upon to interfere, but it is evident that of late he has adopted other views, and a large number of those who have carefully weighed Mr. Chamberlain's recent utterances on the question conclude that whatever may be deductions arrived at by the Commission, he will, by some means or other, succeed in re-establishing confidence in the industry upon which the welfare of so many of Her Majesty's Colonies depends.

The report of the eleventh annual meeting of the Anglo-Ceylon and General Estates Company, Limited, which was published on September 7, has been read with much interest, and, so far as Mauritius is concerned, the operations of the Company during the past financial year were such as to call forth congratulations; but the fact of the Company having been in a position to declare a dividend at a time when foreign bounties were on the increase and the price of sugar materially on the decrease cannot strengthen the hands of those who have been deputed to safeguard the interests of Mauritius in their representations to the Imperial authorities of the difficulties she, in common with other sugar-producing countries, has to contend against. The local manager in Mauritius stated that the equipment of the estates was first rate, and that they had been made to yield a profit owing to the great economy that had been exercised. So far as I am able to gather from the report, if the management be efficient it is possible to keep the sugar estates in good order and to make them yield a profit, even with the ruling bounties and the low price of the staple. There are, however, experienced planters in Mauritius who, knowing the company's estates, are not a little surprised at the figures that have been published setting forth the cost of production per ton. A solution may be ventured by supposing that two accounts have been amalgamated, viz., that of operations on the estates proper and the purchase of canes from planters. Should such be the case, it can be easily understood how the cost of production appears so low—that is, if large quantities of cane were purchased from planters; for it is well-known that there is far more profit made in buying canes for manufacture than there is in growing them. It may be said that the shareholders are indifferent as to how the accounts are made up provided the estates are kept in good order and a dividend is declared; but by the amalgamation of the accounts of the two transactions referred to a fictitious value is given to the properties, as, should planters' canes be unavailable for purchase, the figures showing the cost of production would be sensibly enlarged. Mr. Quinton Hogg's definition of what he conceives to have been Cobden's

ideas on Free Trade appears to be a rational one; each industry was to stand on its own merits—that is, the result placed on the market at the natural cost of production. Anyone who may be sceptical as to the advantages of Free Trade has but to read the Cobden Club's official report, in which are published "Facts relating to Fifty Years of Free Trade," to be convinced of the efficacy of the principle, and, in a measure, to condone Mr. Gladstone's recently expressed views on the sugar question; but, as has so frequently been pointed out, to admit produce or manufactures that are subsidised is an infringement of the principle and productive of ultimate loss to the Governments which give the subsidy and to those which complacently accept the departure from what should be international commercial law. The result of the Mauritius local managers' economical administration, as portrayed in the company's last report, is an object lesson—one that carries with it the conviction that, as regards the sugar industry, the devil is not so black as he is painted?—

Yours truly,
A PLANTER,
Mauritius.

PRODUCE AND PLANTING.

THE TRADE IN BRICK TEA WITH TIBET.—Yatung is the town on the Tibetan side of the Jelep Pass, between Sikkim and Tibet, which was opened to Indian trade by a recent convention with China. A branch of the Chinese Maritime Customs has been established there, and the report on the trade of the place for the past year is interesting reading. It is published in the Yellow-book of the Chinese Customs. At one time there was a considerable traffic between Tibet and Sikkim in brick tea; but no sooner was Yatung declared an open mart, and the question of introducing Indian tea across the frontier mooted, than the passage of Chinese brick tea into Sikkim was prohibited by the Tibetans for some inexplicable reason. Reduced supplies still reach Kalimpong and Darjeeling through Nipal and by other routes. Four kinds of brick tea are still to be purchased in the Chumbi valley at prices which are moderate when it is remembered that the tea has to be carried on pack animals ninety days' journey from the producing districts in Szu-chuan. The lowest quality, which is the tea of the masses in Tibet, is described as veritable rubbish. "Tea flavour it has none, and on careful boiling and examination a brick is proved to consist of mouldy leaves, many of them 4in. long and longer, twigs, sticks 2in., 3in., or 4in. in length, and some of them as thick as a slate pencil; sundry hard lumps of decayed leaves which barely separate when boiled, and, in addition, sweepings, dust, and various dirt. As is well known, the Tibetan system is to positively boil tea leaves; in fact, to make soup of them, and to add salt and butter, or mutton fat, or cheese, just as the decoction reaches boiling point. Thus it is rendered palatable, grateful, and comforting to the native. So far as this quality brick tea is concerned, it may be safely asserted that to European tastes equally pleasant tea could be made from a spadeful of good leaf mould dug from under an old oak, and, if prepared in their own peculiar style, it is doubtful if the Tibetan peasantry would notice any difference in the brew." It seems that during last year 6,444 Tibetans and Tomos, chiefly the latter, crossed the Jelep into the Chumbi valley under passports, and 6,268 went to India from the valley.

PLEASANT IF TRUE.—The disclosures made by the man in the street are not often reliable, and we therefore print the accompanying paragraph, which has been going the usual round of such interesting tit-bits, without vouching for its accuracy. If there is really a trade in second-hand tea leaves it is not surprising that tea is considered by some people to be a noxious drink. Exhausted tea leaves do not inspire respect for tea, and they are not calculated to either cheer, inebriate, or do anything but make life dreary. We should say that tea leaves restewed are very bad for both body and soul, and we

trust in the interest of decency and health that the following paragraph is not a square and solid fact. "Yes," said a man who was collecting tea leaves in the street the other day, "I make a business of collecting used tea leaves. You wouldn't think there was much to be got out of this work; but as a matter of fact quite a good number of men in London make a good living out of it. In a few cases the used tea leaves collected from the better-class restaurants and hotels are sold to proprietors of third-rate restaurants and coffee-houses, who mix burnt sugar with them, and use them for tea-making a second time. The greater quantity of used tea leaves, however, are purchased by proprietors of very cheap groceries. The tea leaves are made ready for the market the second time by being spread upon hot iron plates. The result is that they curl up and present a very good-looking appearance; in fact, tea when recurred in this way looks quite as good as first quality tea that has never been used. And when it is packed in attractive-looking packets it has a ready sale."

ABYSSINIAN COFFEE.—In a report by Mr. Rennell Rodd, H.M. Special Envoy to the Emperor of Abyssinia, recently published in the *Board of Trade Journal* for September last, it was stated that the indigenous coffee of Abyssinia is largely sent to Arabia for re-exportation as produce of Mocha. A question having arisen as to the above statement as regards Aden, a further report has been received at the Foreign Office from Mr. Rodd, stating that in his report the words "sent to Arabia" were not used to specify or even to include Aden, and also that it should be borne in mind that, besides the trade which goes directly to Aden from Zeila and Berbera, a great deal is carried in native boats to the Arabian coast; there is also, it is stated, a considerable movement of shows in the port of Gibouti.

VANILLA CULTIVATION.—Cultivate vanilla wherever soil and circumstances permit is the advice to be gathered from the report of Mr. H. Cockburn Stewart, Administrator of the Seychelles Islands, who, in forwarding his annual report, gives special prominence to the vanilla industry, which is experiencing quite a boom. The crop last year was the largest on record—63,000 lb.—and the prices obtained on the London and Paris markets were such as to delight the hearts of the cultivators. "Nothing pays better than vanilla," remarks the head of the Local Government, and, when the islands are still further opened up by roads, he anticipates a large increase of the acreage under vanilla cultivation.

BOWSTRING HEMP.—A plant at present found in great abundance in South Africa is likely, in the opinion of experts, to become an important article of commerce. This is "the Bowstring Hemp Plant." With the aid of a machine, which has been recently invented, fibres have been prepared from its leaves, which have turned out to be the strongest fibres yet known. This strong quality of the fibre was first discovered by the scientific experts of the Challenger Expedition, who used it to make their deep-sea lines.

PLANTING IN BRITISH CENTRAL AFRICA.—The *British Central African Gazette* has collected reports from various firms and planters engaged in coffee-growing in British Central Africa which point to the continued prosperity of the industry. It is estimated that for this year the crop will yield about 450 tons, and as every year new plantations are being opened up, and areas planted in previous years are coming into bearing, there is every prospect of the supply of coffee from Central Africa assuming very large proportions. One of the largest planting firms reports that "although nobody is yet able to lay down a single rule, we mean a hard-and-fast rule, much less any fixed laws about coffee-planting in this country, for the simple reason that the industry is too young yet, and we are without sufficient data extending over a number of years to go on, still from the experience of the last three years we may

safely say that coffee-planting in British Central Africa is, or can be made, a perfectly safe, steady, and paying enterprise." Experiments are being widely made as to the best kind of shade trees for coffee bushes. Very few new planters have come into the country during the past year, but ten new plantations have been opened up.

LAND IN NEW GUINEA.—According to Mr. T. H. Hatton Richards, who has been lecturing on the subject, cultivators of land who know their business may find British New Guinea a profitable field. As far as was practicable, every inducement was given by the Government to the bona fide settler. All that legislation could do had been and was being done; but, so far, the attention to the country had been rather disappointing. Land might be found for almost every tropical product, but not in the vast areas that were dealt with in Australia, for instance. To the man with experience and a little capital, who chose a moderate quantity of land with care and prudence after personal inspection, good results should follow. He would find two great things in his favour. First, the country was never visited by cyclones. Secondly, with care and tact on his part he should always be able to obtain a plentiful supply of good labour at an extremely moderate rate. But the man who went to British New Guinea must be prepared to rough it in the truest sense of the word, be ready to put his hands to anything, and wait patiently for the fruit of his labours. The chief difficulty to be encountered was the one of climate, and as to this he thought it might improve in time as the possession was opened up for settlement, and it became possible to use the hilly portions of the country for purposes of change.

HONDURAS AND ITS PRODUCE.—Honduras, the land of frequent revolution, is very fertile in the production of coffee, sugar, bananas, coconuts, and other fruit. Java can't produce better coffee. Sugar-cane grows as tall and as sound as a pine sapling. There are no vast plantations of bananas, but each and every adult raises several or more bunches for shipment. Bananas are raised in patches in the shadow of the mountains, in small clearings surrounded by almost impenetrable giant and gorgeous vegetation, around the little thatched roof dwellings and in wells and holes in the ground. Ships, mostly from New Orleans, make regular trips for this popular fruit, and buy it delivered on the boat for 16 cents a bunch. Every bunch must average "eight hand," which, to be sure, is large enough and full grown. Oranges bear two crops a year. Limes, lemons, guavas, and kindred products grow with little or no attention.—*H. and C. Mail*, Nov. 26

THE CHINA TEA TRADE, OLD AND NEW METHODS OF PREPARATION.

The exhortation of the Tsung-li Yamen and the Viceroy of the Liangkiang Provinces [see below] to Chinese tea planters is not calculated to produce any striking results. The exhortation has been issued at the instance of the Minister for the Netherlands, who says that no tea is superior to the Chinese tea in flavour and delicacy of taste and urges that the ancient methods of preparation should be continued instead of being changed for the more modern methods. The Minister would appear to speak in the interests of a limited class of connoisseurs, by whom the delicate flavour and aroma of superior Chinese tea is held in high appreciation, but the amount of leaf required to supply the demand in that quarter can never be large. The great bulk of the consumers prefer the Indian and Ceylon tea and if China wishes to regain her place as the leading exporter she will have to adopt the methods of her competitors. Even in Hongkong, where one would expect China tea to hold its own if anywhere, we find Indian and Ceylon tea largely imported to supply the requirements of the European community, which is a plain indication of the direction in which popular

taste tends. It may pay Chinese growers to produce a limited amount of high class fancy teas for the supply of special markets, but the trade in those descriptions can never attain any great magnitude. It is the taste of the average consumer that must be consulted if the China tea trade is ever to regain its former proportions.

The Viceroy LIU ascribes the loss of so large a proportion of the tea trade to the carelessness and dishonest practices of the Chinese planters, which have allowed foreign teas to capture the markets. There is no doubt a good deal in that, but it is far from being the whole truth. Indian and Ceylon teas are preferred to China tea even when the latter is of unimpeachable quality. Nor must the deterioration of quality be ascribed entirely to the inherent dishonesty of the planter. The unfortunate man, finding his product labouring under a weight of taxation that prevented it competing on even terms with foreign tea, has been more or less driven to pinch the quality in order to retain a margin of profit. It is all very well for the Viceroy to exhort his people to "seek reform in the trade and mutually aid each other in producing carefully prepared high quality teas, and thereby create a new wide demand for the article, which will be followed by general prosperity to all," but if any success is to be achieved in that direction the Government must in the first place lighten the burden of taxation and so give the industry a fair chance.

Given lighter taxation, however, and the improvement in quality and the greater cheapness which might be expected to follow, a reform in the methods of cultivation and manufacture would still be necessary if China is to compete on equal terms for the supply of the general demand, for the small demand that exists for fancy teas will not be sufficient to keep up the volume of the trade. The Tsungli Yamen does not expressly condemn new methods, but urges that "whether their teas are prepared by the old methods or by the new" the inhabitants of the tea planting districts "should always keep in mind the importance of being careful in the work and aim at producing high quality teas in order to command the market." The Viceroy LIU also says he has on former occasions repeatedly exhorted the tea planters in his jurisdiction to introduce reforms into their methods of preparation, etc. What is intended by the Viceroy and the Yamen, however, is, apparently, that reform should proceed on the old lines rather than that an entire revolution in the trade should be effected; for the quotation of the Netherlands Minister's despatch and the general tone of the exhortation seem intended to throw cold water on the attempt now being made at Foochow to introduce foreign methods. Yet it would seem that in the success of the Tea Improvement Company's experiment, coupled with reduced taxation lies the sole hope of a resuscitation of the China tea trade. If the Company has not at once succeeded in producing a class of tea to command the approval of the open market we hope it will not thereby be discouraged, but will persevere until success is achieved. — *Hongkong Weekly Press*, Dec. 2.

AN EXHORTATION TO CHINESE TEA PLANTERS:

THE DUTCH MINISTER TO THE RESCUE.

The following despatch, of which we (*N. C. Daily News*) give a translation, has been received by His Honour Ts'ai Taotai from H.E. Viceroy Liu, of the Liangkiang provinces:—

TO THE TAOTAI OF THE SOO-SUNG T'AI INTENDANCY,
AT SHANGHAI.

I have to inform you that I am in receipt of a despatch dated the 12th day of the 9th moon (7th October) from Their Excellencies the Ministers of the Tsungli Yamen, embodying a despatch of the 24th day of the 8th moon (20th September) from H.E. Knobel, Minister-Resident of the Netherlands at Peking, to the said Yamen to the effect that H.E. had received a communication from the Tea Im-

porters of Amsterdam, the contents of which ran as follows:—

"We regret to find that the samples of tea prepared by the new methods are not very good, but that the flavour of those made by the old methods is still vastly superior to the tea made in other countries. If therefore China tea be prepared after the new methods the leaf will be similar to that prepared elsewhere, while it will lose entirely the original delicacy of flavour peculiar to its place of production. Although the tea-planters of Java, Assam, and Ceylon expend much skill and labour on their products it must be confessed that they do not come up to the teas of China. As matters now stand people in Europe anxious to purchase high quality Chinese teas are unable to do so, and they are compelled to think that tea merchants in China are ignorant of the fact that the people of Europe and other places prefer to buy good Chinese teas to others. The tea made by the new methods in China is really a poor edition of the Indian tea, and therefore vastly inferior to that prepared by the old methods; whilst the prices demanded in England and the Netherlands for high quality [China] tea are three times greater than those asked for teas produced by the new methods. Moreover, tea prepared by the new methods is exported to foreign markets whilst British India tea are also exported to the same places for sale; and the two teas are compelled to compete for buyers. But then there are those [amongst tea consumers] who prefer to drink Chinese tea and yet others who like to drink British India tea. Upon a comparison of the respective merits of the two, however, it has been found that no tea is superior to the Chinese tea in flavour and delicacy of taste. Furthermore, the merchants of Russia, England, the Netherlands and other countries are of the same opinion and have requested the writers of this communication to inform the tea exporters of all China of the actual state of affairs as above explained."

"I, the Minister-Resident, have had the question of the preparation of Chinese teas in my mind for a long time, and after many years' investigation have also arrived at a similar decision as that of the tea importers of Amsterdam and elsewhere, and I have also reason to believe that Your Excellencies will be pleased to learn the opinions above presented."

I would, therefore, earnestly exhort all my people to seek reform in the trade and mutually aid each other in producing carefully prepared high quality teas, and thereby create anew a wide demand for the article, which will be followed by general prosperity to all. This despatch is to be distributed to the various local authorities of the tea districts, who are commanded to make the same known to all our people. Let no one be guilty of disobeying my exhortations. Liu, High Commissioner of Trade of the Nanyang and Victory of the Liangkiang Provinces.—*Ibid.*

THE AUTOMATIC GEM AND GOLD SEPARATOR SYNDICATE, LIMITED.

A CEYLON estate proprietor writes:—

"I see you are noticing 'The Ceylon Prospecting Syndicate' and in case you have not got it, under separate cover I send you a book on the Gem and Gold Separator. I saw it working at home, and I think it should do well out here. I had a letter from Mr. Goldie only last mail: he hopes to be out very shortly." We quote from the circular descriptive of the Ceylon "plant" as follows:—

The plant shewn has been built for the Ceylon Prospecting Syndicate, Limited, 10 St. Swin's Lane, E.C., and will be sent to their Mines near Rakwana, Ceylon. The mines consist of deposits of alluvial gravel, containing Sapphires, Rubies, Spinel, Cat's-eyes, Zircons, Topaz and alluvial Gold. The gravel is trucked or sluiced to the head of the plant at the rate of about 8 tons an hour, or say 60 tons a day of 8 hours. Such gravel may contain boulders, clay, sand, sticks, roots and the like, but all are

shot promiscuously into a large revolving Grizzly which arrests and throws out anything that will not pass between bars 1 inch apart. The clay is broken up and washed through the bars and this, with the gravel and fine sand, passes on to a puddling machine which reduces the clay and washes it and the sand out together.

The washed gravel is then elevated by means of a bucket elevator to a classifier, which screens it into eight sizes, ranging from $\frac{1}{2}$ -in. to $\frac{3}{4}$ -in.; and each size is then fed by a band elevator into a special separator, which, by means of a current of water, automatically selects the gems and gold, their specific gravity being slightly higher than that of the worthless gravel, and discharges the latter into the tailings shoot, which conveys it away to the dump. The Gems and Gold are deposited in locked receptacles, from which they may be removed from time to time by an authorized person holding the keys. The main object to be accomplished is to perform all the above operations automatically, and without possibility of theft during the passage of the gravel through the plant, the difficulty of preventing theft of so small and valuable a product having hitherto been an insurmountable obstacle to the successful washing of gem-bearing gravels on a commercial scale. It will be noticed that the gravel cannot be seen, nor a handful of it in any way obtained, throughout the entire series of operations until the Gems are safely deposited under lock and key and the gravel finally discharged.

The weight of the plant is about 20 tons, and it is erected on a steel gantry, which requires only a few logs of rough timber as foundation. It is made in small parts for easy transport, and can be dismantled and re-erected when necessary, without skilled labour. The cost without driving-power is about £1,500, and the plant shown is being driven by a small 6 H.P. engine. Water-power is applicable, if available, for driving and, with this advantage, that the tail-water from the motor may be used again in the washing plant. The machinery at Westbourne Park is working with only about 1,000 gallons of water, pumped round and round by a small auxiliary engine. In most cases a supply of water will be available from a local source, so that the return of the water in this way will seldom be necessary. As the plant is automatic and one man can take charge of several plants, the working expenses are extremely low.

The machinery shown is suitable for Diamonds, alluvial Gold and other minerals in coarse sizes. Plant to deal with crushings from rolls or stamp-batteries is built on the same principle with some necessary modifications, the Grizzly and puddling-machine being dispensed with. For the ores of lead, tin, zinc, copper, and the like, it has special advantages, and is particularly suitable for tender ores such as Cinuabar. —November 1897.

CEYLON AND CHINA TEAS.

Mr. Thos. Fairhurst, the well-known merchant of Foochow, and Ceylon estate proprietor, who left by the homeward bound mail steamer "Valetta" has stated to a representative of your contemporary that when China teas were made in the European fashion the leaf did not seem to answer. It was neither China tea, nor Ceylon, nor Assam; and he did not think it was going to be a success. Experiments had not been made on a large scale, however, and Mr. Fairhurst said they were trying to enlarge the Foochow Tea Improvement Company, in order to see if they could not extend operations. He does not think that success is at all likely, because from his observations the leaf does not seem to answer made up in the Ceylon way. It produced a very good looking tea, but there was no flavour in it.

In his opinion it would be a long time yet before a new style of China tea is ready to compete with Ceylon.

He did not think China looked like resuscitating her tea trade to the danger of the Ceylon trade? "Is not a good deal of your China, made tea green?" He was asked and he replied:—"Only

about ten per cent, and they do not seem to care much for it in America, or anywhere else as far as I can see. I believe people here at one time feared competition with China, but now, my impression, after spending a fortnight in Ceylon, is that they do not think there is anything in it. The fact is that as the output of teas like those made in Ceylon goes on increasing ours must proportionately decrease." With regard to the Straits he said that it struck him Liberian coffee was going to be a big success in spite of the white ants and other troubles. It was only a question of what price it would realise. It would grow well enough and it was only a question as to whether it would command a price to secure a big profit.

THE "ANNATTO" INDUSTRY AND OTHER MINOR PRODUCTS IN CEYLON.

The high prices paid for the seed of *Bixa Orellana* by one who is known to be the largest grower of the dye in the island, and the only exporter of the manufactured article, has attracted attention. Planters will now think, that after all, annatto is a paying product and that it was a great mistake to destroy the trees in some instances to make room for tea. The same might be said of croton oil seed which of late has been fetching high prices in the home market. Vanilla also comes under the same category; so do cardamoms. But let the cause of this sudden rise be carefully considered, before any one embarks in the re-cultivation of these products on an extensive scale. Two years back annatto seed was locally obtained at 10 cents a lb., and croton R6 per cwt.—not because there was no demand for them at that time, but rather because the output from different parts of the island was then much greater than it is now. The present prices will keep up as long as the present output is not exceeded and it must be borne in mind that the world's demand for these minor products is very limited.

TEA IN FORMOSA.

Tamsui, Nov. 20.

The tea season in Formosa has closed. The total production runs about 450,000 half-chests, which is about the same as last year. The duty question in America disturbed the market considerably and it is reported that there have been some heavy losses in consequence. Japanese as yet have made no serious attempt to enter the tea business either as planters, packers, or exporters, with the single exception of one company which packed some 12,000 half-chests and exported via Kelung and Japan some 800 half chests to America. The Japanese Government rendered great assistance in officially endorsing a movement made by the merchants to prevent the export of impure teas. It has been the custom of an occasional unscrupulous Chinese dealer to import inferior Amoy teas, mix them with Formosa's, and then export the product as pure Formosa oolong, also to add extraneous matter to Formosa. But the Government has now invested a committee consisting of three foreign merchants and four Chinese merchants with the authority to confiscate and burn all such teas found on the market, while the salesman of the same will be fined a sum double the amount he has named as the value of the teas. Several seizures of spurious teas were made during the season and it is quite reasonable to believe that there will be but few attempts made to dispose of false goods on this market during the coming season.—*China Overland Trade Report*, Dec. 2.

GOOD ADVICE.

Somebody gives the following good antithetical advice:—"Drink less, breathe more; eat less, chew more; ride less, walk more; clothe less, bathe more; worry less, work more; waste less, give more; write less, read more; preach less, practise more."—*Indian Witness.*

COFFEE PLANTING IN BRITISH CENTRAL AFRICA.

The following are Messrs. Buchanan Brothers' estates in the Zomba District:—
Mlungusi Estate, about 70 acres, is the oldest plantation in the country, some of the coffee being 12 years old, and still bearing well.

Chirunga Estate, 120 acres, was opened in 1891 with 10 acres, additions being made every year. This year 50 acres have been added.

Namiwawa Estate, 100 acres, was begun in 1893 by planting about 20 acres, additions being made every year.

Likangala Estate, 60 acres, was opened in 1890. No additions have been made since 1892 to this estate.

Should the expectations of the Manager be realised, the crop for next year from the Zomba Plantations will be at least 40 tons of coffee.

Messrs. Sharrer have three plantations in this district, viz., at Zomba, Namitembo, and Likangala.

MLANJE DISTRICT.—The Nyasaland Coffee Co. have opened up 630 acres this year, all of which they hope to plant during the coming season. Carl Wiese opened up 100 acres last year, about 50 of which are planted. Further extensions are to be made during the coming year on this estate.

Mr. Richie of the Likulesi Estate informs us,—“We have now got about 220 acres under coffee, 60 of which has been planted out this year, and the seedlings look fairly well considering the long spell of dry weather they have had to fight against. We have now 160 acres four years old. When two years old it gave us 250 lb.; last year 9 tons 16 cwt.; and this year we expect to get 14 tons, picked off little more than 50 acres. These trees of course are still young, and taking everything into consideration I do not think we can grumble. The rainfall has been very insufficient indeed, there having been only a few showers after the end of January. We generally get a few days rain about the end of September and the beginning of October; this brings out the blossom right enough; then we get six or eight weeks of scorching sun and by the time the rains are on us in December, the primaries are likely to be burned black. This has occurred here for two years in succession on coffee that has never given a crop. Irrigation has been tried, but was not a success owing probably to insufficient supply of water. Of insects, the *White* (or *mealy*) *Bug* is the greatest enemy we have in the plantation here; it is most disastrous to the plants on which it may settle. *Red Spider* is visible during the dry season, but is always exterminated by the rains. We have a quantity of *borer* amongst the oldest plants, but nothing to any extent. With reference to shade it is now well understood amongst planters that we must have shade for coffee, and I think that most of the planters on Mlanje are going in for shade. On one block of 140 acres we are planting fig cuttings and they are breaking well. They are planted 25 feet apart, with the view of course of thinning out if necessary. We are also raising a nursery of *Grevillea Robusta* which we intend planting out as a shade tree.”

The Mount Zion Estate of Mr. Bradshaw is comprised of,—

50 acres	7 years old,
50 acres	6 years old,
100 acres	4 years old,
50 acres	3 years old,
50 acres	1 year old,

A total of 300 acres, under shade one year old, *Albizia* mostly. The coffee returns from the above has been so far very satisfactory.

The Bloomfield Estate owned by the same gentleman consists of 250 acres under cultivation and another 50 being opened. This estate is also under *Albizia*, planted 24 feet apart.

Mr. A. C. Simpson, of the Ntundulima Estate, one of the oldest planters of Mlanje, does not think the coffee prospects of B.C.A. are of the brightest. He has tried cattle manuring and green manuring with no appreciable result. The fault is not to be found in the soil, as he says it has been proved to be suitable by analysis. Shade has not helped Mr. Simpson, as crops taken from coffee under bananas and other shade has not increased, but in fact, has decreased, as though the coffee trees look much better under shade, they do not bear such large crops.

The rainfall, he states, is the secret of non-success as the rain comes at the wrong time, heavier showers being required in September, October, and November.

Mr. Simpson states it is his opinion that for this reason coffee will never pay in B.C.A.

Mr. H. Cox of Ntundulima Estate intends putting the whole of his plantation under shade, using by preference native species of the fig (native names “*Tundu*” and “*Katchesi*”) and the “*Kundu*” tree. He is of opinion that the crop of 1896 would have been much larger than it was had more of the estates in B.C.A. been under shade. The promise of the blossom was very good indeed, but the crop did not come up to expectations owing to the coffee trees being parched by the dry weather, being in many estates quite unprotected.

The use of shade will also enable the planter to fight more successfully against the ravages of the *borer*. *Borer* has not been so bad this year on Ntundulima owing to the fact that many infested trees were cut down last year.

Mr. ERIC AUSTEN of the Stewart Estate only commenced operations in March, 1896.

Mr. H. BROWN'S DUNRAVEN ESTATE has some 170 acres under cultivation, and this year he has opened something like 150 more. Mr. Brown believes in shade. His house has been roofed with shingles, the first to be used in this country, made from native woods.

Borer is fairly active, and entails a good deal of labour in cleansing the trees. The estate also suffered last year from the prolonged drought.

Mr. JOHN MOIR of LAUDERDALE has also had a smaller crop than was promised by the blossoming, owing to drought. *Borer* is seen in parts of the plantation. On some of the new coffee plants there is white marking on the leaves. The larvae of a brown weevil was also found this year in some berries. *Black bug* was easily disposed of by washing with soapy water.

Albizia muluccana seedlings planted for shade in February last year are over 4 feet high with a good spread. This appears to be a suitable tree for shade. *Grevillea robusta* and native fig cuttings are about the same height, but they do not appear to give such a good shade. Some coffee under bananas is doing very well but then coffee under shade, although the trees may be in splendid condition, is said not bear a large crop.

Mr. Moir has this year cut semicircular trenches a short distance from the coffee trees and filled them with manures. This has been done on the side looking north and next year a similar semicircle will be made and filled with manure on the south side, thus completing the circle round each coffee tree. Trees treated in this manner are said to develop very strong wood.

In between the coffee grass has been strewn on about 12 acres and left. This has been done with the idea of keeping the ground cool and moist. It is open to the objection that an accidental fire might destroy the coffee trees.

The hole on the Zomba plateau has recently been explored by Captain Brake and Mr. Gough of the B. C. A. Rifles. Having taken up with them a coil of stout rope Captain Brake was the first to descend, being lowered with a light to the bottom, Mr. Gough following afterwards. An immense pile of human skulls and bones was found at the

bottom, the hole having evidently been considerably made use of as a burial place. According to native accounts the last body buried there was about three years ago. The depth is about 60 feet.

The ivory which was reported to have been thrown down some years ago was not discovered, nor were there any relics whatever. A shot gun dropped down some time ago by Mr. MacDonald was recovered not very much the worse for its exposure.

The natives expressed great fear when the intention of exploring the hole was made known to them, but after Captain Brake had been drawn safely up again they recovered their spirits.

It is feared that the prolonged drought may cause some damage to coffee. This appears to have been the driest year on record, practically no rain having fallen in Zomba since the end of the last rainy season.

From reports received from the West Shire and Ruo Districts there is reason to believe that Rinderpest has made its appearance among the game in those districts.

Information has been received that game is dying in numbers in the Elephant Marsh. Prompt measures have been taken to endeavour to prevent its introduction into the Shire Highlands. In another column appear a few notes by Doctor Kerr-Cross as to the best method of preventing and treating the disease taken from reports and papers published in connection with the outbreak in South Africa.

The segregation of herds of cattle can be more easily carried out in this country than in the South and this is one of the greatest safeguards against the introduction of the disease.—*B. C. Africa Gazette*, Oct. 18.

THE AGRICULTURAL MOVEMENT IN ZANZIBAR.

Here is an example for the Ceylon Government in regard to backward districts. We quote from "The Shamba,"—a journal of agriculture for Zanzibar :—

A very successful Shauri was held at Weti on October 24th in connection with the work of the Agricultural Department of Zanzibar. Hamis bin Salm, the Li Wali had summoned the Arabs to meet Mr. Lister, Government Agent for Pemba, and Mr. Lyne, the Director of Agriculture, who were travelling through. The most significant feature of the meeting was the interest which some of the leading Arabs, notably Mohammed bin Jumah of Kish Kash and Mohammed bin Jumah of Mikindani, took in the matter. The Li Wali took the chair and in a brief speech explained the objects of the meeting and called upon the Arabs for their interest and support. Mohammed bin Jumah of Kish Kash followed with a very energetic address. The Arabs, he said, were too fond of sleeping and eating, and never bestirred themselves to any work, but the time had now come to make an end of all this. Mr. Lister next rose and said he had been among the people of Pemba now for eight months and during that time had made many friends both among Arabs and natives and he now appealed to that friendship for a fair and impartial hearing. He asked the Arabs to believe that what he had to say on behalf of the Government was sincerely said for their own welfare. In travelling through Pemba he had been struck by the fact that many people completely misunderstood the nature of their work. Most people seemed to think that because they were members of the Government that their only business was to help in taking their slaves away. He and Bwana Lyne had nothing whatever to do with this. Their business was with the land, the shambas, the cloves and chillies, coffee and cocoa, rubber and vanilla, all trees and plants; what to grow and how to grow them, how to prepare them for the market and so on. They all knew that cloves had been falling in price and that Arabs were not so well off as they were three or four years ago. The Zanzibar Government saw that if the people did not begin to grow something in addition to cloves

they would get less and less money each year and probably in the end be all ruined. And so the Government wrote home to Europe for a man to come and try and find out what would be the most suitable plants for these islands to grow. That was what Bwana Lyne was now doing at Dunga. He had many sorts of trees at Dunga and all the work that he was doing there was for the assistance of Arabs and their shambas. But it was no use trying to help the Arabs unless the Arabs would help themselves. They must try and improve their shambas. Each shamba should have a nursery of young trees for planting out as the rainy seasons came round. Every shamba had a lot of waste ground upon it, and if each Arab had planted out say 100, 500 or 1,000 coconut trees, according to the size of their shambas, they would soon become valuable estates. As it was many of them were almost worthless on account of being neglected. It was a work not of one year but many years. Bwana Lyne would get now seeds and plants for them but they must ask for them, and if they got them he would come round and see that they looked after them properly. They should all buy a copy of the *Shamba Gazette* which was written especially for Arabs. They could buy it every month from the Hindi Hashim in Weti for one anna. The Arabs should write letters to the *Shamba* if they did not understand anything, and their letters would be printed and answered. Rev. J. Key in proposing a vote of thanks to the Li Wali for his trouble in collecting the people said he himself felt very strongly about these matters. The whole system of cultivation in Zanzibar could be improved upon. Many of the products such as cloves, copra and chillies reached the London Market in a disgraceful condition and in nearly every crop which the Zanzibar planters grew they were at the bottom of the market.

CEYLON PLANTERS IN THE STRAITS.—In the district report on Kuala Langat, in Selangor, for October, it is noted that applications for land for planting have been received from Messrs. Munro and Carey at Morib, and an application for permission to take up the whole of the island opposite Jugra, received from Mr. Carey on behalf of Mr. Wiggan, of Ceylon, is now being considered and dealt with by Government. The area of the island is said to be about 30,000 acres. In view of the increasing activity in the district, it is a matter for regret that the only means of ingress by land—viz., the road from Klang—is in a very bad condition. Since the advent of the rains, the road is little better than a quagmire.—*Straits Times*.

FIBRE-YIELDING PLANTS.—A writer in the latest *Indian Forester* just to hand condemns the fibre of *Calotropis gigantea* ("Wara" of the Sinhalese) as comparatively useless: his letter will be found on another page. We cannot understand this experience after what we were told about the value of this fibre. Mr. Macdonald's report should clear up the discrepancy.—We have had placed before us by a Ceylonese land-owner, an appreciable quantity of fibre—rather coarse but strong—which he obtained without much trouble from the stems of *Hibiscus esculentus*, the well-known plant yielding the "bandekai" vegetable of our dinner table, described as follows in our "Gardening in Ceylon":—

BANDIKAY—*Hibiscus esculentus*.—The long capsules when young may be boiled and served like asparagus and are very delicate, or sliced and put into soups or curries. Seeds in good light oil, in drills 2 feet apart. This plant is easily grown and if it turns out that besides supplying a useful vegetable, it yields paying fibre, the cultivation might well prove profitable in the neighbourhood of our lowcountry towns. We are sending the fibre to London for report.

MINING AND GEMMING IN CEYLON.

APPROACHING VISIT OF AN EXPERIENCED
MINING ENGINEER.

We said the other day in discussing Mr. Lockhart's Patent Gem Separator and the Plant now on the way to Ceylon, that we were on the eve of new and important developments of local Mining and Gemming Industry. We had, of course, partly in view, the approaching Geological Survey of the island which, we hope is not to be much further delayed and the important results which may be expected to flow from it, as well as from the success of the Patent Separators in our Gemming regions. We have now another "departure" to report. Our old friend (and one of the shrewdest Colonists that ever came to Ceylon) Mr. C. Tottenham in a letter just received, reports that he is sending out to Ceylon, by the Orient steamer "Oroya" a Mining Engineer of great experience in Capt. Leonard Tregay. The primary object is to inspect and report to Mr. Tottenham on some extensive plumbago deposits on his Monarakanda plantation, Gallagedera. But Capt. Tregay will be open to engagements elsewhere in the Colony after he has discharged the mission confided to him on Monarakanda. The very fact of his being selected by so experienced and competent a judge as Mr. Tottenham is enough testimony in our opinion to the merits of Capt. Tregay; but our readers may like to know what Mr. Tottenham has to say of him in writing to us:—"Captain Tregay although not a scientific geologist has a true miner's instinct, comes from a mining family, and has been mining in many parts of the world in gold, tin, copper, and iron chiefly—with all of which he is thoroughly acquainted. Capt. Tregay is almost the only mining man I have ever known—and I have known many—on whose thorough honesty, one can perfectly rely. Like other mortals he may be mistaken, but it will be an honest mistake anyway. I have known Capt. Tregay for a quarter of a century, and for much of that time he has been associated with me, in charge of mining properties I was sole or part owner of, and I have rarely found him mistaken. I have asked Captain Tregay to have a good look round while in Ceylon, and to let me know what he thinks of our mining prospects generally. I have asked him to have a good look at our quartz formation for gold amongst other things. A man like Captain Tregay would be *invaluable* in connection with the proposed Geological Survey, you have so strongly advocated, and which now I am glad to see is to be undertaken. Capt. Tregay when he has done my work, goes on to Western Australia on a visit and to report on mining property there I believe." We think the Colony is greatly indebted to Mr. Tottenham for sending so experienced a mining authority into our midst; and we feel sure that owners of land likely to have plumbago deposits, cannot do better than put themselves in communication with Capt. Tregay, in order that he may make an inspection after he has finished on Monarakanda. If any letter for our visitor should be sent to this office, it can be handed to him on arrival.

We are almost afraid to reopen the question of "gold" after the many abortive attempts in the past; but clearly no such practical and ex-

perienced expert as Capt. Tregay has ever come to Ceylon before this time, and it would be a great advantage that he should inspect some of the spots associated by the Sinhalese from time immemorial with the finding of gold—in Rangalla, Ramboda (Rangboda), Ruwanwella, &c.; and if he goes so far, Capt. Tregay should see the quartz near Badulla recently referred to by Mr. Haly of the Museum. In our ironstone, especially the "15 miles of ore" in Sabaragamuwa, referred to by Gygax, Capt. Tregay would be certain to take a special interest if only he can be brought to the "location." He is sure also to have a "look-in" at the Ratnapura and Matara gemming pits, and to take an interest in Mr. Lockhart's new "plant." As respects the Geological Survey, of course the Ceylon Government is committed to the officer—Mr. Oldham probably—who is to be sent to us from India; but we can fancy that Mr. Oldham himself would be delighted if he had the chance of having the assistance of a practical mining authority of long experience like Capt. Tregay, and this might lead eventually to an engagement for the latter in India, when his mission in Western Australia is completed. It certainly seems a little puzzling as to why paying gold reefs should not be found and opened among the quartz hills of Ceylon (and Travancore) as well as among those of Mysore and the Nilgiris? Capt. Tregay's opinion on this matter will be very valuable one way or the other.

PLANTING NOTES.

THE BENGAL UNITED TEA CO., LIMITED, is one of the latest of new Tea Companies and is to hold 5,245 acres of tea in Assam, Cachar and Darjeeling—the capital being £300,000. Altogether the properties cover nearly 20,000 acres. The capital issued is only equal to £40 an acre of tea, not counting the 14,000 acres in reserve!

PEPPER is grown at the Straits on a big scale when a single estate despatches as reported by the District Magistrate, Kuala Kangsar, as follows:—

The weight of pepper shipped to London from Chigar Galah estate was 97 pikuls 33 katis. When shall we see estates in Kegalla district doing this?

THE SPRING VALLEY COFFEE COMPANY, LTD. —The Directors of this Company have decided in a circular, dated 9th November, "That no interim dividend will be paid at the present time, as the Board consider it advisable to adopt the same policy as last year, and let the dividend on the ordinary shares stand over until the annual accounts are presented to shareholders. The £15,000 preference capital recently issued was over-applied for and has been allotted, all works connected with the speedy development of the estate as a tea property are therefore being actively pushed forward. This year we are planting 186 acres of tea and 134 acres of fuel, and it is hoped that all the remaining area under coffee will be planted up next season. Plans for the additional factory accommodation for dealing with the increasing quantity of leaf have been approved by the Board, and this work will be put in hand at once. Latest reports from the estate with regard to tea are in every way satisfactory. The dividend on the preference shares will be paid half-yearly, viz.:—On 1st February and 1st August."

"RECORDS OF THE GEOLOGICAL SURVEY OF INDIA." Vol XXX, Part 4. 1897, has for contents:—On Nematite from Afghanistan. By F. R. Mallet, late Superintendent, Geological Survey of India; On a Quartz-barytes rock occurring in the Salem district, Madras Presidency. By T. H. Holland, A.R.C.S., F.G.S., Geological Survey of India (with a sketch map); Note on a worn femur of *Hippopotamus iravadicus* Caut. and Falc. from the Lower Pliocene of Burma. By Fritz Noetting, Ph. D., F.G.S., Paleontologist, Geological Survey at Jaintia. (With Plates xix and xx.); On the Supposed coal of India, Buxa Duars. By H. H. Hayden, B.A., B.E., Officiating Deputy Superintendent, Geological Survey of India; Percussion Figures on Micus. By T. L. Walker M.A. Ph. D., Assistant Superintendent, Geological Survey of India; Geological Notes; Donations to the Museum; Additions to the Library.

THE CONSOLIDATED ESTATES COMPANY, LTD.—(Messrs. Arbutnot, Latham & Co., Great St. Helens, General Managers) are to purchase the Horana Group of estates, comprising about 657 acres in the Kalutara district of Ceylon, of which about 426 acres are planted with tea, with tea factory and machinery complete. This group of estates is conveniently situated for the business of the Company, and the price at which the estates have been acquired is considered a very favourable one. The price paid for the estates is a little over £15,700, in addition to which some fields planted with tea adjoining the estates, with expenses of transfer, will probably bring the total cost to nearly £18,000. To cover this, the Company are to issue, £7000 in 5 per cent. Debentures at par, £7,000 in 8 per cent. Preferred shares at £1 per share premium, £7,000 in ordinary shares at par, and these issues are to be offered to the shareholders.

THE BENGAL GOVERNMENT CINCHONA PLANTATIONS.—The Government cinchona-plantations and quinifactory in Bengal appear to be almost as profitable as those in Southern India. From the rather complicated accounts published in the annual report of these plantations for 1896-97 it is difficult to arrive at the exact profits on the year's working, but it is apparently half a lakh of rupees. The total factory output of sulphate of quinine was 14,124 lb. The Naduvatom factory made 7,891 lb. during the same period, so that Government manufactured in all just two tons of quinine last year. Most of this goes to meet a new demand that would not exist but for Government undertaking the distribution. In the Bengal report it is stated that cinchona-febrifuge is bought largely by the non-official public who are under no sort of compulsion to use it in preference to other febrifuges, but who do so because they find it such an efficient medicine. There is, for example, a single native medical practitioner in the Jessore district whose purchases of it last year exceeded the official consumption of the whole province of Bengal.—*Ibid.*

RUBBER IN ZANZIBAR.—One hundred and fifty Para rubber trees have been taken from the Dunga nurseries and planted out at Tundaawa, Pemba. They have been placed 25 feet apart and cover a space of a little over 2 acres. Up to the time of writing, all, with the exception of seven, have taken hold and show every sign of growing rapidly. The locality is low sandy swampy ground though not actual swamp. The "Para" rubber tree appears to be especially fond of light and sun. It was found that trees grew much faster if the shade were removed as soon as signs of renewed vitality became apparent. The great thing is to keep the roots moist and well mulched with grass or leaves. The mystery of the Pemba rubber forests has at length been cleared up. No one was more ignorant of the locality and nature of the reported forests than the Pemba people themselves, particularly those who lived almost in the middle of it and all around it. Natives are loth to leave pathways, hence a black forbidding wood is to them a thing to be avoided, as it means sore feet.—*Shamba.*

RUBBER AT THE STRAITS—is going to be done on a large scale to judge by what the Acting District Magistrate, Matang, says in his monthly report:—

Mr. Stephens of Jebong estate has applied for some 3,000 acres of land for rubber planting in accordance with the terms of the circular that lately appeared on the subject.

New rules for land have just been promulgated by Sir F. Swettenham as follows:—

CULTIVATION OF GUTTA.—As it is the desire of the Government to encourage a comparatively new industry, it is hereby notified that land applied for the cultivation of gutta can, for the present, be granted on the following terms, which, however, will only be given to the first six successful applicants, after which they will be cancelled. (a) *Quit-rent*.—Ten cents an acre for ten years, afterwards fifty cents an acre. (b) *Cultivation*.—In concessions of 1,000 acres or less, at least one tenth of the land granted to be planted with gutta of any description, every year, no other form of cultivation being permitted so long as the land pays a quit-rent of ten cents per acre only. In concessions of over 1,000 acres and not exceeding 2,000 acres, one twentieth to be planted in each year. If over 2,000 acres and not exceeding 3,000 acres, then one thirtieth to be planted in each year. (c) *Duty*.—An *ad valorem* duty of 2½ per cent for fifteen years from date of commencing work. After that the duty in force for the time being; such duty not to exceed 5 per cent. (d) The above conditions to bind the lessee and his assigns, alienation of the land being unrestricted.—*1st December, 1897.*

THE POSITION OF VANILLA.—It is believed—says the *New York Drug Reporter*—that a syndicate is in control of the situation, so far as vanilla imports from Mexico go, and one view is that the reports from Mexico during the past three years of damage to the crops have been colored to serve the ends sought by the manipulators; but on the other hand, the shipment last April of 42 cases of the crop of 1894-95 is thought to confirm the reports of actual shortages in the crops. The action of the Mexicans has seriously curtailed the consumption of the Mexican bean. Dealers have ransacked the markets of the world for the other varieties. That they have been successful in securing supplies is attested by the importations. During the past two years about 40,000 pounds of Tahiti beans per annum have been received here, as against annual average of 15,000 in the preceding three years. Thus far in 1897 about 570 cases, or 57,000 pounds, of Bourbon beans have been imported. Only in rare instances have dealers succeeded in persuading their customers to continue to use none but the Mexican beans. Most of the users have mixed the cheaper varieties with a certain proportion of the Mexican beans, and in instances a small quantity of vanillin has been added to produce and extract of the flavor desired. The consumption of vanillin has increased enormously, the drop in the price from \$5.50 per ounce to \$1.70 (in fact to 90 cents before the new tariff became operative) having been coincident with the advance in the price of beans. While it is probably true that the artificial product does not produce that same rich flavor in the extract that the best Mexican bean does, a very large quantity of the cheaper extracts are used, and unless the price of Mexican beans is speedily reduced, it is very doubtful if there will be an outlet for the former average crop of 1,000 cases, even at the prices which existed before the upward movement commenced three years ago.

PROGRESS OF NORTH BORNEO AND THE PROSPECT OF TAXATION.

The recent action of the British North Borneo Government in notifying the increase of certain duties might have been anticipated by any one who knows the history of the Chartered Company. Established in 1881 by Sir Alfred Dent and some influential men like Sir Rutherford Alcock, whose death has so lately been communicated to us, the Chartered Company have seen their attempt prosper, and after sixteen years of paternal Government the territory can boast of a well established planting enterprise which is gradually increasing and comprises tobacco, coffee, gambier, pepper and other plantations in addition to the sago plantations which existed in 1881. Some of these have advanced to a paying stage, but no revenue is as yet collected except from tobacco which pays one cent a pound or in other words about one per cent of the value. We also have a well established timber trade with China, and the shipping engaged includes two steamers of 1,347 tons and 825 tons respectively which maintain a very valuable and constant communication with China whence a large proportion of our labour force is drawn. Time was when the Chartered Company paid a bonus on each trip to China and a large proportion of the ten thousand pounds sterling expended in the eighties on introducing Chinese immigrants had to be expended on chartering steamers to convey the immigrants; and even after the timber trade with China commenced the Government subsidised steamers and gave assisted passages from China by tickets issued here and in China. This paternal care extended to the trade with Singapore and it was only in 1891 that the subsidies to foreign steamers ceased. Since then the expansion of the trade with Singapore has enabled the shipping companies to hold their own, and today we are witness to the competition for this trade by the China Mutual Shipping Association which has lately commenced running two steamers from Singapore. But while watching the development of their territory, the Chartered Company have not benefited in any material way on the capital they have expended—a little over half a million sterling—except in 1889 and 1891 when dividends of 2½ per cent were paid, and in August of this year when the modest men of 1 per cent dividend on the paid-up capital was declared. On this last occasion the shareholders pointed out that the capital expended might fairly be viewed as a National Debt on which the Directors should try to pay a fixed rate of interest, as is done in all civilised countries. This suggestion naturally brings the Government face to face with its Revenue duties and the late increase imposed on the export of timber commended itself from several points of view. The duties formerly imposed were very low, and in the case of sawn timber were *nil*; moreover, when the first duty was placed on timber, exchange stood at a higher figure than it does today. Exchange is now so low that a profitable timber trade may be done with Europe, and the small increase in the export duty will probably not materially affect such a trade. Another point of view is that the timber exported was not grown by the timber companies, and it is only taken from the most easily accessible points along our coasts and rivers, and is therefore worked at the minimum of expense; and if the Chartered Company is ever to receive any return from this valuable asset it must be today, and

before these points are denuded of their natural forest growth. It may fairly be expected that, as the desirable timbers are exhausted along the frontage, increased knowledge and more effective appliances will reduce the working cost. Up to the present it is an open fact that want of capital has not allowed our timber companies to do justice to the magnificent stores of timber so freely laid open to them, and from this point of view the opinion has been expressed that it would be better to prohibit small exporters from entering into the trade. From yet another point of view the present is not an unfavourable time for increasing the timber duties as the prices ruling are fairly favourable, and exports have consequently increased from Sandakan, while Kudat has lately added some 5,000 to 10,000 cubic feet per month. Looking to the future it may naturally be expected that the Chartered Company will expect established industries to pay for the benefits accruing from a well established government. The paternal sympathy with the growing interests of the Colony are today exhibited by a continuance of the old steamer-subsidising policy which has largely assisted the establishment of the local Sabah Steamship Company which maintains frequent coastal inter-port communication and is a dividend paying concern, profitable to those concerned in it; and last, though not least, by the erection of a telegraph wire across the territory and by the construction of a Metre Gauge railway now being constructed from the West Coast to the interior. All this cannot be done without money, and it seems but fair to expect a small return on the capital expended on the development of the Colony. The history of the past sixteen years is a record of patient waiting and of hopeful anticipation that the Colony established by the Chartered Company would pay its way. This has become an accomplished fact and the next hope to be realized is that the Colony may pay a fair return on the capital expended. This also seems to be in a fair way of realization, not by imposing heavy Customs' duties but by so carefully levying duties as not to be a hardship or a deadweight on advancing trade. There are some articles on which a heavy duty, properly placed, would benefit trade. Our sago now sells for twenty-five per cent. less than Sarawak sago, a difference entirely owing to our allowing the natives to export it in a filthy, raw state; and the action of the Government in the future taxation of this product will probably lead to a much higher value and to large, local, sago cleaning companies which will be domiciled on our shores and add to our population. The Government has no intention of departing from its policy, hitherto maintained, of assisting trade and enterprise in every legitimate way; we offer our land at nominal prices, and we offer to give land for nothing under certain conditions; but at the same time it is to be expected that we shall ask for the return of a small percentage of the incomes extracted from the land and from the trade which the Government of the Chartered Company has been so successful in building up.—*British North Borneo Herald*, Dec. 1.

THE GUTTA-PERCHA CORPORATION, LIMITED.

(From the *Daily Chronicle*, Dec. 2.)

Capital £200,000, in 80,000 seven per cent. cumulative preference shares, 120,000 ordinary shares, both of £1 each, of which the whole of the preference

shares and 80,000 of the ordinary shares are now offered for public subscription. This company has been formed to trade in and manufacture gutta-percha, and to acquire and work a patent process "to obtain gutta-percha from the leaves and twigs of gutta-percha trees by an efficient and economical method." The prospectus goes on to show that there is room for a considerably increased supply of gutta-percha, which has advanced in price during the last few years, mainly owing to the wasteful method by which it is obtained—viz., by cutting down the trees. At the same time, to pay £150,000 for a patent which may possibly be very good, but which, so far as we can gather from the prospectus, has not yet been worked on a commercial scale, is, we think, too much, and it makes the company a very speculative venture. We think the patent should have been worked by a syndicate, and its merits fully ascertained, before being sold to a company at such a high price.

AUTOMATIC GEM AND GOLD-SEPARATOR.

Although sapphires, rubies, spinels, cat's-eyes and other precious stones command good prices and a ready market, it has hitherto been an impossibility for companies formed to promote this particular branch of mining to become really successful, owing, principally, to the fact that they were unable to prevent theft during the process of washing and picking the gems from the gravel. This obstacle has now been surmounted by Mr. William S. Lockhart, M. Inst. C.E., M. Inst. M.E., the inventor of the Automatic Gem and Gold-Separator, and our representative had the pleasure of inspecting a complete plant, which has been specially manufactured for the Ceylon Prospecting Syndicate, Limited, the other day at the works of Messrs. Clayton, Howlett and Co., Woodfield Road, Westbourne Park, W. The mines where the Separator will be erected are situated near Rakwana, Ceylon, and consist of deposits of alluvial gravel, containing sapphires, rubies, spinels, cat's-eyes, zircons, topaz, and alluvial gold. In order to give our readers an idea as to how the plant performs its duty, we may say that the gravel can be trucked or sluiced to the head of the plant at the rate of about 8 tons an hour, or, say, 60 tons a day of eight hours. The gravel is shot promiscuously into a large revolving Grizzly, which arrests and throws out anything that will not pass between bars 1 in. apart. By this means the clay is broken up and passes with the gravel and fine sand on to a puddling machine, which reduces the clay, washing it and the sand out together. A bucket-elevator immediately carries the washed gravel to a classifier, which screens it into sizes, ranging from $\frac{1}{8}$ in. to $\frac{3}{4}$ in.; and each size is then conveyed by a band elevator into a special separator, which, by the aid of a current of water, automatically selects the gems and gold, their specific gravity being slightly higher than that of worthless gravel, and discharges the latter into the tailings shoot, which carries it away to the dump. The gems and gold are deposited in locked receptacles, from which they may be removed by an authorised person holding the keys. The above operations are automatically accomplished and it would be impossible for anyone to appropriate a particle of the valuable product during its transmission through the plant. The machinery is suitable for diamonds, and also deals successfully with alluvial and pyritic gold, free-milling, refractory

and telluride ores. Some modifications, of course are necessary to treat crushings from rolls or stamp-batteries; for instance, the Grizzly and puddling machine, mentioned previously, are dispensed with. The weight of the plant is stated to be about 20 tons, and it is erected on a steel gantry, possessing the advantage of being made in small parts, and therefore, can be easily transported. The machinery at Westbourne Park is driven by a small 6-h.-p. engine, and is working with only about 1,000 gallons of water, pumped round and round by a small auxiliary engine. The separator is especially applicable to Western Australia and other countries, where water is scarce, as the same supply can do duty over and over again. We may mention that Rakwana is one of the best gemming centres of the Ratnapura district of Ceylon, so that with the aid of the Automatic Gem and Gold-Separator, the Ceylon Prospecting Syndicate may look forward to a prosperous career and to the inauguration of a profitable industry.—*The Mining World and Engineering Record.*

CLUB ECHOES AND TEA LEAVES.

I do not know whether the idea may not have already been ventilated in Ceylon, but it occurred to my mind the other day in glancing over one of the Reports of the United States Department of Agriculture to wonder if

CAMPHOR

had ever been tried as a bye-product in your island. From the report mention it appears to be a tree, which grows well under widely different conditions. It grows in Egypt, Madagascar, Buenos Ayres, the San Joachin Valley in California, the Canary Islands, and the South East of France as well as in its native Japan. In Tokio the trees are subject to a winter of from 70 to 80 nights of frost, but the conditions of really of successful cultivation seem chiefly a temperature never below 20 degrees F. in winter, plenty rain, in the growing season, and a nitrogenous soil. The camphor is distilled from the wood of the trunks, roots and larger branches, and the work is all done by hand. The wood is felled, cut into chips and placed in a tub something like a churn, size about 40 inches and narrower at the top than the base. A tight fitting cover is then put on. A bamboo tube from the tub connects with a condenser in which the oil is separated from the camphor crystals. Twelve hours is required for the distillation of a tubful. Twenty to forty pounds of chips go to each pound of crude camphor; and from Lewis and Peat's last fortnightly price list I see that Chinese camphor sells in London at 92s 6d a cwt. and Japan at 100s.

THE AMSTERDAM CINCHONA MARKET.

The 8,216 bales and 627 cases of Java cinchona-bark offered by auction at Amsterdam on December 9 weighed 753,859 kilos. According to analysis, they contain the equivalent of 40,793 kilos, of sulphate of quinine, or an average of 5.64 per cent. The tone of the market remains extremely firm. On Tuesday, December 7, 42 tons of cocoa-butter will be offered for sale at Amsterdam. These include 10 tons of "Hammer" brand (Dutch), 10 tons of "Helm" brand (Dutch), nearly 5 tons of "Holland" brand 9 tons of Suchard's (Swiss), and 7½ tons of "Mignon" brand.—*Chemist and Druggist.*

PRODUCE AND PLANTING.

THE BULKING QUESTION.—The bulking question, like the problem of the poor, is always with us in some form or other. The latest point at issue has been whether the place of hulking should be mentioned in the catalogues. As will be seen from a report which appears elsewhere, the members of the Indian Tea Association are by no means unanimous on the matter, and suggest that, for the present at any rate, Indian tea producers should be allowed to follow their own sweet will as to whether this information be given or not. As was pointed out in the discussion at the meeting, no valid reason has yet been put forward for giving the information on the catalogue, and if it is required, it can at all times be obtained at the warehouses. At the same time it may appear only reasonable to meet the views of the trade by stating the fact that the tea has been hulked in London when this has been done. It is certainly, however, strange that any dealer should prefer to have tea turned out of its original air-tight packages, thus absorbing the moisture in the London atmosphere, and losing not only its aroma but also its keeping qualities, merely to ascertain whether there was any country damage or not in the package. It looks as if the whole question has been raised in the interests of the warehouse-keeper to swell his profits, and to place a tax on the planter. It is a well-known fact that the cost of bulking on the factory does not amount to more than 2d. a package, while the warehouse charge for hulking an average chest of tea is 1s. 5d. It will be seen, therefore, that the planter stands to lose 1s. 3d. a chest by this demand for bulking in London. On a garden producing 6,000 boxes of tea this would form an annual charge of £375 for doing in London what could be done far better on the garden.

NATAL TEA.—There is a steady development of tea cultivation in Natal, and this year's crop may reach a million pounds, which would constitute a record. Natal's tea trade with the Cape and the Transvaal is gradually increasing, and the local demand is larger. Messrs. Hullett and Sons have just erected in Durban large double-story warehouses and offices and are also opening out in London.—*H. & C. Mail*, Dec. 3

TEA IN AMERICA.

New York, Nov. 24.

At the last auction sale prices were off, and some lots sold at very low figures. Fancy Formosa brought 38c. This is strange in view of the better tone of the foreign markets, notably London. One of our foreign exchanges says:—"So far as the producer is concerned, the position and outlook of the tea market is favorable. Already the large distributing retail companies are showing some anxiety on the subject of supplies. Shipments from China have shrunk to small dimensions; the Indian crop is, so far less than last season, and there is only a small increase from Ceylon. Meanwhile consumption at home and abroad increases, and a steady depletion of stocks in the United States is taking place, the quantity in bond being 5,000,000 pounds less than it was a year ago. The tea trade of the United Kingdom, including re-exports, is now at the rate of 275,000,000 pounds per annum: the cocoa trade, which is rapidly increasing, is at the rate of 50,000,000 pounds weight."

The imports of tea, as reported by the United States Bureau of Statistics, for the nine months ended September 30, compare with the same time in 1896 as follows:—

Tea imported from—	Pounds.
United Kingdom	1,778,513
British North America	328,857
China	28,214,238
East Indies	782,236
Japan	19,776,294
Other Asia and Oceanica	49,237
Other countries	7,470
Total	50,937,445

[The figures affording comparison with 1896 are not given]—*Ed. T.A.*

NEW YORK, Nov. 23, 1885.

Editor American Grocer.

There is something inconsistent in the actions of the leading tea importers. They petitioned Congress to pass an act to exclude cheap and nasty teas, and said that if their suggestions were carried out, the standard of teas in the United States would be higher than in any other country.

Well, their suggestions have been the basis of the new tea ordinance, but we find they still demand the cheapest and coarsest teas. *Excluding dust, which does not come here, the average price of pure, uncolored tea in London has been for the last few weeks about 9½d. (say 19c).* Yet importers seem to fix a limit of 12 to 14c, laid down in New York—a price at which only the sweepings of the London market can be secured.

The margin between this importing price and the price to consumers is surely great enough to allow ample profit, even if importers raised their limits to a figure which would enable them to buy *average teas*. This rich country should be able to afford itself food products of average quality.

Apart from this aspect of the matter, there is the important fact that with an improved *quality* of tea, an equal quantity would make 50 per cent more cups of tea. Other Anglo-Saxon countries consume three to five times the quantity per head that we use here, simply because they import the good quality, leaving the rubbish to come to America.—Yours, etc.,

DISTRIBUTOR.

TEA CULTIVATION: FLAVOUR AND MANURES.

A very delicate as well as important question is suggested in the course of an interview by an *Observer* representative with Mr. A. Baur who has just started the Colombo Manure Works. We have great faith in the experience and shrewdness of Mr. John Hughes and should be inclined to take his advice on any point affecting our tea culture; but we submit that only practical experiment can decide as to the effect on the flavour and aroma of our teas, of certain specified manures. *Prima facie* there would certainly seem to be good reason to object to certain rather unsavoury fertilisers, not only for the objection specially mentioned, but in view of the risk of introducing disease; but, on the other side, we have the fact of a good many years of experience appertaining to not a few plantations in the use of some, at least, of the fertilizers repudiated; while again many of our old coffee-planters used to think that the introduction and too free use of artificial manures had somehow to do with the succumbing of their coffee bushes to tungus and green bug. There is nothing, therefore, like having the whole question looked into and the way in which individual planters can settle it for themselves, it seems to us, is by giving a perfectly equal trial to the different ingredients mentioned. One acre or a-half or a-fourth for each plot—so long as all the plots are fairly equal in soil, lay of land, age and treatment of trees—ought to suffice and if the different manures are applied at the same time, and some trouble taken to keep the results in crop, flavour and value of tea, separate, and to report fairly on the appearance of the trees,—a very valuable object lesson should be the result. Meantime, we have no doubt that Mr. Hughes' opinions and recommendations will receive very careful consideration from our planting readers, leading to enquiry and practical experiments.

PLANTING AND MANURING IN CEYLON.

Mr. A. Baur, who is well and favourably known in commercial circles, has on his return to the island, after a course of study at the Swiss Agricultural station of Zurich, and consultation with the best known agricultural chemists of France, and Mr. John Hughes, who has so extensive and intimate an experience of Ceylon soil, climate, and planting, devoted his business energies to the pushing of the sale of manure. His attention was naturally directed to the subject on account of his being a proprietary planter himself, and after perusing the correspondence, which had appeared in our columns, last year, on the manuring of tea estates he put himself in communication with a friend, who was a doctor of agricultural chemistry and who had originally gone out to Sumatra, under engagement to assist and advise planters of that colony. That expert advised him as to the qualities and defects of the manures in common use here, and this advice he followed up as we have already stated when he went home recently by securing the opinions of those who had given special care to the subject on the continent and in England, Mr. Hughes, in whose judgement must be placed the greatest value, expressing the opinion that no blood, raw bones and fish should be used as strong smelling substances taint the flavour often, and that unless first treated with acid, these materials were dangerous, there being a risk that they might introduce some fungus disease which should certainly be a warning to planters considering the havoc done by the coffee leaf disease.

Mr. Hughes was very particular as to the ingredients to be used and that their composition should be such as to suit the nature of the soil, crop and climatic conditions of low-country and up-country estates. There will however be this further advantage that his mixture can be made up in any proportion which planters with practical experience on the subject, may deem best suited to the requirements of their soil. Mr. Baur, who has made a special study of manures and of the principles of manuring will be very glad to give every possible information to planters and at nominal expense to secure analysis of their soils and obtain the best professional advice so that they may be induced to give the new method a trial which he feels confident will result in the adoption of more scientific manuring. Mr. Baur further assured us that his mixtures were made up on the most up-to-date scientific principles and that he was ready to guarantee the quality of the materials as being only first-class. He also pointed out the defects of the present system of manuring by which very often a good deal of the most expensive of the manurial constituents gets lost without taking any effect on the plants and claims that his mixtures will effectually overcome this drawback and that they will therefore prove to be a more economical manure.

With regard to his Works at Vauxhall Street, Mr. Baur mentioned that he was importing special machinery for grinding and mixing, as it was very important that the ingredients should be carefully mixed, so as to ensure each plant getting the proper percentage. As to the motor power he was going to have a 25 horse-power oil engine which is considered the most perfect type of its kind, one advantage being that the engine is guaran-

teed to require cleaning of its inner parts only once every six-eight months. All the machinery is expected to be here by February, and we are sure from Mr. Baur's business enterprise that he will achieve a very fair measure of success indeed.

COLOMBO TEA SALES.

The results arrived at by Messrs. Forbes & Walker for the year 1897 as compared with 1896, differ a good deal from those given by Messrs. Somerville & Co. as may be seen from the following:—

(From Forbes & Walker's Circular.)

	OFFERED. packages. lb.	SOLD. packages. lb.
1897*	426,298 = 33,886,803	335,866 = 26,512,099
1896*	402,219 = 32,083,163	320,225 = 25,412,624

Increase 24,079 = 1,803,640 15,641 = 1,099,475

(From Somerville & Co.'s Circular.)

	OFFERED. packages. lb.	SOLD. packages. lb.
1897*	425,582 = 33,788,217	322,755 = 25,630,499
1896*	403,295 = 32,005,564	318,770 = 25,403,345

Increase 1,782,653 227,154

80 lb. is said to be about the average of a package of Ceylon tea—can the test be safely applied?

THE CHINA TEA TRADE.—“The Chamber of Commerce Journal” to hand by last mail contains a full report of a paper read by Mr. Geo. Jamieson, C.M.G. (H.B.M.'s Consul at Shanghai) on “The Effects of the Japanese War and Prospects of British Trade,” from which we quote the following:—

TEA TRADE

furnishes another and an even worse instance of how a great national industry is being ruined by the folly and indifference of the governing classes. It is only yesterday, as you are aware, since China supplied nine-tenths of the tea consumed in this country, and now I do not suppose she supplies a tenth. It is asserted, and I do not doubt it, that if foreigners were allowed to introduce machinery into the tea-growing districts and superintend the preparation of the leaf, China tea could even yet hold its own against the best that India and Ceylon can produce. But no such prospect, I am afraid, can be held out. The treaty gives us the right to buy from the Chinese such tea as they prepare, but not to grow and prepare it ourselves. I was consulted, just before leaving Shanghai, by a small syndicate who were very desirous of getting machinery introduced into one of the large tea-growing districts as an experiment. The proposal was to co-operate with a native company, who would be the owners of the plan, and employ as superintendents the necessary foreign staff. The plan seemed feasible enough, but it came to nothing. The native tea-men had not the courage to risk their money. They did not know what the officials would say, or probably enough they got a hint that the officials would not have it, and so the whole thing fell through. I am, glad, however, to observe that something of the kind is being done at Focchow, where a supply of leaf can be procured near the port. A foreign company has got some tea-firing machinery into operation with, it is said, the approval of the officials, and I trust this may be the beginning of a new departure. It is not particularly in the interests of China tea as against Indian that I say this, but in the interests of China trade in general. For unless the exports from China can be increased neither can her imports. What she exports does not matter, neither does it concern us what country it goes to.

* Total to 22nd Dec.

PAYMENT BY RESULTS.

It is impossible, in almost any walk of life, to do absolute justice to all classes, by any rule of universal application. We have all appreciated the obstacles which the old system of nomination to official appointments offered to justice. Had those with whom nomination rested been both clear-sighted in judgment and free from all taint of prejudice or partisanship, there would have been no need for change in the system; but men, however high-placed, being only human, the best candidates had often to give place to the most influential or the most showy. Competitive examinations were suggested as the best means of checking favouritism; but even on the assumption that perfect fairness obtains in the setting of papers and the awarding of marks, the candidate who obtains the highest number of marks may be far from being the ablest in intellectual power or deep reading. And even if he is the ablest, he may be deficient in character, or in aptitude for business, or in physical ability to do justice to his duties. The student is not always a practical man; and the cleverest student may prove a poor Administrator or be wanting in the Judicial instinct. Competition is accepted as, perhaps, the best test that has been suggested though far from being perfect, or even safe in many cases. Then, in regulating promotion, after admission has once been obtained into a Service or Department, we are confronted by similar difficulties. Seniority is regarded as an old-world tradition; and when any other system is adopted it opens the door to favouritism and to the advancement of the more plausible or complacent. The very necessity for the Re-organization Scheme which has been adopted as applicable to the Civil Service, is connected with the difficulties we have been considering of doing justice to the individual on the one hand, and the community he serves on the other; and the drawbacks even of that Scheme are neither few nor imaginary, as we have seen.

The difficulties which beset officialdom are present with the private employer of labour, but certainly not to the same extent. The latter has fewer interests to consider, fewer critics to appease. He deals with what is, in a sense, his own; and not a trust for the community or the country. Though a conscientious man will reckon whatever he has as a trust to be administered with care and circumspection, he can disregard all criticism when he feels he has done what is right; but still, awkward questions may arise, and have arisen, in regard to one's duty to one's employees; and the present contests between capital and labour, are but the expression of the difficulties we have indicated. One of the fairest and most reasonable solutions of these difficulties is to be found in giving the employé a pecuniary interest in his master's business. There are obvious difficulties in the way of a general application of concessions. Who are the employés who are to be allowed this modified partnership? What is to be the extent of their share in the profits? If profits are to be shared, why not losses? These are details which offer difficulties; but none of them are insurmountable; and it is being very widely recognized now by far-seeing employers of labour that, both good work and loyalty are best purchased, by

awarding to labour a share in the profits which it has the power to develop or lessen. In this view, we have always favourably regarded the action of local Plantation Proprietors who have offered their Superintendents something more than a living wage; who have provided for increments, at stated intervals, for good work: or better still, have held out the inducement of commission on profits, in order to create a closer feeling than is generally associated with payment for work. So far from considering the time inopportune for suggesting the division of dwindling profits from Tea, we are strongly of opinion that one of the most effective means of arresting the falling-off in profits, if not of materially increasing such profits, would be to offer the Manager or Superintendent a share in whatever is netted beyond the latest returns—or beyond the average for two or three years. The interesting and instructive letters we received in response to our Tea Circulars, show how great and diverse are the responsibilities of a Superintendent, from day to day, and how widespread a feeling there is that all Superintendents do not attend to the manifold details of their duties as closely as they possibly might. What then is the best incentive to persistent effort, and to close attention to worrying details which one might with propriety leave to subordinates. Surely it is the offer of some benefit for extra trouble. It is impossible to bind people to hours in certain classes of work, just as it would be the height of un wisdom and cruelty to be guided by the law of supply and demand in regulating wages for duties which it is impossible to define. In keeping down advances, in exacting task work, in conciliating labour, in visits to the field and the factory, there is a vast difference between what can fairly be expected from a Superintendent, and what a careful, thrifty Proprietor will do for himself. The latter is the standard to be aimed at, and that can never be secured by rules and regulations, and any amount of supervision. Personal interest is required; and a share of the profits is the best inducement. For these reasons, we commend the action of Companies which encourage their Superintendents by an annual bonus; but we are inclined to think that the better course would be, after the example of the Advertiser in our columns for a Manager for Travancore, to offer Superintendents and Assistants a share in profits, or a commission, beforehand. We should then hear less of complaints like those which "Greatly Interested" suggests—complaints for which we would fain hope the occasions are few and far between.

THE CINCHONA CULTIVATION COMPANY *Pasir Nangka*, of Java, has declared a dividend for the last year's trading of 13.4-5ths per cent.

A NEW STEAM TURBINE.—Our (London *Times*) Rotterdam Correspondent informs us that two Amsterdam engineers, Mr. van Gink, managing director of the Cycle and Machine Factory de Hinde, and Mr. W. J. Holsboer, have invented a steam turbine which (according to a report in the *New Rotterdam Gazette*) will cause a revolution in steam engineering. The inventors have sold their system, it is said, to a German firm for one million marks, preserving for themselves the application of the system to gas and benzine motors; and have taken a patent for it in several countries.

THE CEYLON AND LONDON SHARE
LISTS—IN 1896 AND 1897.

CEYLON COMMERCIAL COMPANIES.

The following comparison is afforded by simply taking the local Share Association's list of yesterday's date and placing alongside the quotations in the similar list for 22nd December, 1896. The falling-off in the value of the shares of some of the local Tea Companies is very striking and shows how lack of confidence (due to lower prices, higher exchange and continued extension of cultivation) and scarcity of money have told on the financial standing of our local Tea Estate Companies. The last cause—scarcity of money—has also affected some of the more purely commercial or trading Companies; but these, as a rule, stand the comparison much better. So also, strange to say, do the London-Ceylon Sterling Tea Companies, and we are aware that, in their case, the quotations for the local market are not so good as those given in the London share lists. Several new Companies (some of them absorbing small Companies appearing in 1896) have to be noted, and also care must be taken to discriminate between Tea and other Plantation Companies. In one or two cases the value of the shares has been either reduced or increased (more capital called up) and this must be allowed for. Nevertheless the comparison afforded by the table cannot but prove instructive, not the least noteworthy fact being the readiness of so many holders of shares to "sell" at this year's quotations:—

COFFEE AND ANTS.—Here is a receipt for driving ants away from coffee beds. It is sent to the *Straits Times* from Kuala Lumpur:—Dig where the black ants are to be found, and sprinkle cold wood ashes as much as may be necessary. This will drive away the black ants, and will probably prevent the white ones from coming up. The ashes will not only drive black and white but even red ants, and can be used to keep these little parties away from almost every object dear to their tiny hearts.—*B. N. B. Herald*, Dec. 1.

FRENCH COLONIES: HOW A COFFEE INDUSTRY IS (NOT) STARTED.—Says the *Daily Chronicle*:—A Paris contemporary tells an admirable story of French colonial administration. Some little time ago, 500 coffee plants were in store at the public garden of a French colony. The director conceived the happy idea of distributing these amongst the natives, and the suggestion was warmly approved by the Governor, who next day issued a proclamation to this effect:—

Art. I.—Any native requiring coffee plants must apply in writing to the authorities. Art. II.—This application must bear a penny stamp. Art. III.—The request must be countersigned by the head of the Second Department. Art. IV.—It must further be stamped by the head of the First Department. Art. V.—The director of the gardens must keep a strict account of the plants delivered.

It is, perhaps, needless to say that coffee culture still languishes in that particular colony. In the Belgian Congo State private traders buy up the plants and give them to the negroes, making the advantageous stipulation that they shall receive half the produce. One hardly knows which method is the more to be commended.

THE VISIT OF THE MINING ENGINEER.

CAPT. TREGAY, M.E.—of whose mission to Ceylon we gave a full account, quite a week ago—passes a few days in Colombo before going upcountry. He will probably go to Kandy on Monday next and next day to Monerakande estate, and there, with the Manager, Mr. A. J. Thomas he will enter on the special undertaking which has brought him to Ceylon. He is meantime reading up local literature bearing upon the Mineralogy of the island, our compilation "Gold, Gems and Pearls" being new to our visitor. We have mentioned the "gold campaign" entered on during the dark days of the Colony a decade ago, and how more than one mining expert then inspected some of our quartz reefs and directed how shafts should be driven, although they could not remain on the spot themselves to see the work completed. The most elaborate investigation was made by Mr. A. C. Dixon, B.S.C., &c.; but though a scientific man, Mr. Dixon had had no experience as a prospector or mining engineer. In Ambagamuwa and Dolosbage districts chiefly were the reefs examined. Capt. Tregay considers that too little time was given to the quartz reef trials; for, he holds with all other authorities that where gold is found in the streams as in the Mahaoya and some others of our rivers, there ought to be gold-yielding quartz not far off. At the same time, we know that gold is the most widely and finely distributed of metals and poor old Robert Dawson's saying about gold in India and Ceylon—has clung to our memory since he first repeated it over thirty years ago—"Gold in Ceylon?"—he would say to the enquirer,—"why, of course, gold is found in the sands of every river here, just as in Southern India, where, when a man has nothing else to do, he goes and washes for gold and makes his two fanams a day—and it is on record that a man once made four fanams (6d) a day!" There is no doubt of gold existing in our hill formation; but whether it is in an accessible and paying form is the problem. Still, there are the profitable mines in Mysore and Coorg to encourage investigation; and here comes Mr. Domenico in a letter elsewhere, to tell us how he found very appreciable evidences of gold below the Morawak-korale District in the Southern Province. Proprietors with likely quartz on their estates in that District should write and engage Capt. Tregay to pay them a professional visit. Our visitor has had very great and varied experience in both Victoria and New South Wales, in California, South Africa, Siam, Chili as well as in Europe, and he comes to us with the highest possible recommendations. We trust wherever Capt. Tregay travels in the island he will meet with courteous attention and all possible information of which he may stand in need. Our native Plumbago Pits or Mines and Gemming Districts' operations ought to interest him very much; and our readers will learn of Capt. Tregay's impressions at the close of his inspection. Meantime, Capt. Tregay's address after Sunday next, will be care of A. J. Thomas, Esq., Monarakande, Madawallatenna.

appointed is to act for Uva generally and is exceedingly well chosen as representative of the different districts in the principality. Very practical resolutions bearing on the subject were carried; and we trust Mr. Farr may be gratified by finding other divisions of the country establishing branches after the pattern just set in Uva.

THE AGRICULTURAL SCHOOL.

As an old believer in the Agricultural School and in its judicious well-trained Principal, Mr. Drieberg, we are delighted with the brave defence of the institution put forth in his Report reproduced on another page. It is monstrous that in this colony so purely agricultural, the one institution that should wither for want of proper encouragement and support is the Agricultural School. The Report very clearly shows where the institution is placed at a disadvantage as compared, with other not more deserving establishments for whose encouragement much more is done; and we sincerely trust that as the outcome of the present Commission, the Agricultural School in place of being allowed to lapse, may be established on a really liberal, sound basis and may prove the successful, progressive seminary which Ceylon should specially have in connection with its horticultural, agricultural and even planting interests. Several valuable suggestions were made by successive speakers and, the Mayor, who made a splendid Chairman, gave a most practical, enlivening as well as inspiring address—although he rose eventually to a point a little beyond the present generation. We must walk before we attempt to sour into the empyrean! Still, there is nothing like holding up a high ideal. With some of Mr. Davidson's illustrations of the backwardness of the community in its interest in Agricultural teaching we are rather puzzled. We do not know that we have ever seen the paper which he said provoked no criticism; but surely he cannot accuse the planters of the island or the city writers who fill the *Tropical Agriculturist* or Mr. Drieberg and his contributors who give us the excellent *Agricultural Magazine* with being at all backward in their interest in the main industries of the Colony. The rest of the world or "balance of creation" regard Ceylon (and its *T. A.*!) as the fountain-head of information on nearly every branch of Tropical Agriculture. We can only trust that Mr. Davidson and Mr. Obeysekara and Mr. Peris—if not on the Agricultural School commission already—will be individually asked for their advice and suggestions by the Commissioners, whoever they are, in reference to the School of the future. Meantime, it is refreshing to hear of Mr. Drieberg's headquarters being the centre of so much useful activity, and of the paying investments of Government that are represented there. May such activity, and success continue and expand largely through the influence which a well-adjusted, liberally-conceived Agricultural School is certain to exercise in the time to come.

THE GALAHA TEA COMPANY.

The shareholders of the Galaha Ceylon Tea Estates and Agency Company, Limited, held their first annual general meeting at the offices of the Company, 39, Lime street, London, on Tuesday, 7th December, Mr. C. E. Strachan, Chairman. After the notice convening the meeting had been read.

CEYLON GAME PROTECTION SOCIETY.

We direct attention to the letter of Mr. Farr—who is ever in the front in such matters—giving cover to an interesting report of a meeting lately held in Haputale in connection with the establishment of a local branch of the Ceylon Game Protection Society. The Committee

The Chairman, in moving the adoption of the Report and accounts, said—The accounts, duly certified by your Auditors, and the Report, have been in your hands for some days, and have, no doubt, been carefully read by all interested in the Company. I trust, therefore, you will allow me to take them as read. In moving their adoption it is only necessary for me to say a few words, as the Report deals fully with everything, and states the causes of the differences between the estimated and actual results of the season, and you will see that these are causes over which the Directors had no control. The crop turned out 829,000 lb. of tea and 19,240 lb. of cardamoms, against our estimate of 880,000 lb. tea and 20,500 lb. of cardamoms, or a shortage of about 5 per cent. This may be considered close and careful estimating when you bear in mind the large acreage, the different ages of the tea fields, and the different aspects and climates, which had to be considered. At one time there was every reason to expect a considerable excess on the estimate, but the last two months of the season were unpropitious, and very little crop was harvested. With regard to price, we based our estimate on the return of the two previous seasons, but, in the case of tea, there was an unexpected fall, and we only realized 6½d. per lb. against the estimate of 7d.; while, in the case of cardamoms, there was a substantial rise, but the extra amount obtained for the cardamoms did not, of course, cover the difference in the price of the tea. Then we had exchange against us owing to the action of the Indian Government, and we also sustained a loss in rice, an advance in price being caused by the famine in India. As far as rice is concerned the crop reports from India are favourable, so there should be a decline in price soon, but about the course of exchange I can say nothing—high exchange is, of course, much against us, and I can only hope that the Indian Government will be unable to maintain its action. But, in spite of the circumstances I have detailed, the Company has done well, and it says a great deal of our properties, and business that, last season, with less than two-thirds of our tea in bearing, we are able to pay so good a dividend. With respect to our progress we have, as the Report tells you, added 200 acres to the acreage, opened 218 acres of new land, completed the Factory which is now able to deal with the crops for some years to come, provided new line accommodation for the larger force of coolies required, erected a hospital and doctor's bungalow, and, in fact, done nearly everything necessary to make the estates complete. All this expenditure has added materially to the value of the properties and to your security. We spent £1,418 in manuring, which amount was charged to current expenditure. Little or no benefit was derived from this last season, but it will be reaped in the future. This item alone represents nearly 3 per cent. on the ordinary share capital. I only mention this to let you know that the properties are being thoroughly well cultivated and cared for. During the present season we are opening 422 acres of very fine land, and we hope to have the tramway at work, and to complete all buildings in course of construction. The capital expenditure after this season will be small, as very nearly all this work is completed. The acreage in bearing and in partial bearing this season is 2,047 acres of tea, from which we expect 1,026,000 lb. I leave it to you to judge what we are likely to get when the

whole 2,774 acres in tea are in full bearing, and I will only say that the larger quantity will, I believe, be produced at a smaller cost per lb. The Directors have not lost sight of the necessity of creating a reserve fund, but at present we are developing the properties, this being considered the best reserve that can be made, forming as it does a solid basis for future profits. With all the buildings completed and fully equipped, and with so large an acreage of the best land to come into bearing, the prospects in my opinion are decidedly cheerful, as the whole business is a sound working concern.

Mr. JONAS, a shareholder, said that in one sense the declaration of the final dividend of only two per cent. on the ordinary shares was disappointing, after an interim dividend of five per cent. as it could hardly be expected that such a large proportion would be declared for an interim payment. The Chairman explained that at the time it was considered by the Board to be fully justified, and that there was every reason to anticipate the payment of ten per cent. for the year, but, owing to the unforeseen circumstances already mentioned, the estimate had not been obtained.

Mr. Low enquired if any allowance were made for depreciation, and what steps had been taken to maintain a fuel reserve.

In reply, the Chairman stated that nothing had been written off this year for depreciation, most of the machinery being new, but that in future this important matter would be borne in mind; as to fuel reserve there was a large acreage in timber in addition to the belts of timber on the estate.

The CHAIRMAN'S motion to adopt the Report was seconded by Mr. HARWOOD, and unanimously carried.

The CHAIRMAN also proposed the payment of a final dividend of two per cent. in respect of the 5,000 ordinary shares, and this being seconded by Mr. Evans, was agreed to, making a return of seven per cent. for the year.

On the proposal of Mr. Low, seconded by Mr. Dunphie, Messrs. Fuller and Wise were duly elected Auditors.

The proceedings closed with a vote of thanks to the Chairman.

MADAGASCAR UNDER THE FRENCH.—From a commercial point of view this seem to have already proved a very unfortunate matter for trade. The "Tariif Général" has been introduced and the result is (says the correspondent of the *British Trade Journal*) that the whole trade of Tamatave is turned topsyturvy. Here are two instances of the troubles that have arisen:—

Ten cases of tea arrive from Ceylon, each of which contains 150½-lb. packets of tea packed in tin-foil. The Custom-house authorities exact that every packet be opened, the tea poured out in bulk, and the tinfoil weighed apart, as it pays a duty of 13s. per 100 lb., while the tea pays 2l. per 100 lb. Result: the tea is virtually ruined. *Morton's goods*, of which there is an enormous consumption in Madagascar, have to pay 35 per cent. on invoice price. The other day a merchant presented his *declaration* as: per invoice of three cases "mixed pickles." Every case has to be opened, and amongst these mixed pickles were found several bottles of *piccalilli*. The underlings immediately drew up "a court of accusation," and condemned him to pay a fine of 35l., because *piccalilli* contains curry powder, which pays 35 per cent., although the saffron root from which it is ground pays nothing.

THE CACAO FUNGUS SPECIALIST.

Mr. Carruthers is very busy with his investigation and hopes to be able to throw light on the origin and cause of the cacao plant disease, by-and-bye; but obviously the investigation is not one to be hurried, and will require time to deal with it. An upcountry correspondent (not a cacao planter) writes:—

I had the pleasure of travelling with the cacao expert sent to Ceylon by cacao planters for the purpose of investigating into the cause of death amongst the cacao trees.

That the canker is there, and the deaths in some of the fields are very numerous are facts beyond dispute. The cacao planters have an able and energetic Specialist amongst them in Mr. Carruthers and it is a fortunate circumstance, for he has a hard task before him, ere he can confidently say, "Here gentlemen is the cause of the disease and death, but prevention is better than cure and this is what you must do." Is the cacao enterprise of so little importance in Ceylon, that the Government should not be asked to contribute towards the cost of this investigation? I think Mr. Editor you will agree that His Excellency ought to come forward without being asked, and at least hold out some prospect of reward, and afford every facility for a thorough examination into the cause of so many deaths amongst the cacao trees of Ceylon. We have the man; let Government now provide the means.

"Hear, hear" we emphatically add; or at least, "let the Government supplement the means."

SALT FOR AGRICULTURAL PURPOSES.

"In the name of the Prophet——SALT!" After all, the Government wound up the somewhat controversial if not stormy sitting of the Legislature, with a very acceptable concession to public opinion as represented by the Tamil Member. A Committee to enquire into the denaturalising of Salt so as to be available duty-free for agricultural purposes was granted to Mr. Coomaraswamy, and the Colonial Secretary went further in showing his personal interest in the subject in a very satisfactory little speech. The area of "inland estates" likely to use salt has considerably increased since 1888, and we do not see why the demand for denaturalised salt should be confined to palm cultivation. So that the question may arise in an urgent form as to how the 150,000 (rising rapidly, perhaps, to 250,000) cwt. of salt required for local agriculture, are to be provided. Better means of manufacture and transport will be indispensable and a further reason will thus be adduced for the Railway to Puttalam. Meantime we congratulate the Hon. P. Coomaraswamy for bringing this long-standing request so far to a practical issue and we heartily trust that the labours of his Committee will be crowned with success (we had almost written with salt!) and then he will certainly deserve well of his countrymen even if the operation of the "five years' rule" bring his present term of service as Legislator to an early close.

The report of the discussion is as follows:—

The Hon. the TAMIL MEMBER moved:—That a Select Committee of this Council consisting of the Hon. the Auditor-General, the Hon. the Treasurer, the Hon. the Principal Collector of Customs, the Hon. A. De A. Seneviratne, the Hon. W. W. Mitchell, the Hon. J. N. Campbell, and the mover be appointed to consider and report upon the feasibility of selling salt at cheap rates for agricultural purposes.

He said:—It is not my intention, sir, to say more than a few words in support of this motion. It is admitted on all sides that salt is benefi-

cial to agriculture and especially coconut plants. It is largely used in other parts of the world, but in Ceylon because it is a Government monopoly and sold at prohibitive rates, the planters find difficulty, in using it as a manure. The Government makes a very good thing out of it, sir. I find that the revenue from this monopoly is certainly a million rupees a year. According to the Blue Books the cost of production is 32 cents per cwt. and it is sold at R2.40 per cwt. The profit therefore is R2.8 per cwt. and there are about 400,000 cwts. produced annually. Any amount of salt can be produced and the more it is produced the less it costs. Therefore I think the Government should find no difficulty in supplying planters with salt as manure. There is certainly one difficulty. The Government will naturally argue, if we supply salt at cheap rates as manure, how are we to prevent it being used for other purposes. Now, sir, this is a question that was solved elsewhere 30 years ago while we had gone to sleep over it. In January, when I went to Europe, I had the opportunity of meeting a German gentleman. One of the subjects we discussed was the Salt Monopoly here, and he told me that the King of Prussia, as far back as 1867, passed a law whereby the mode of denaturalising salt was fully laid out, and salt was sold cheaply, not only for manuring, but for another purpose—fish-curing—about which the Government had been very anxious, but which they had not been able to carry out before, owing to the difficulty to which I have referred. On my return I mentioned the circumstance to Mr. John Ferguson of the *Ceylon Observer*, whom we all know; and he has published a pamphlet giving full information on the subject and containing a translation of the German law which any member can read for himself, and see that it is most simple. Competent authorities in Ceylon declare that what has been carried out successfully for the last 30 years in Germany can with equal success be carried out here. I am sure that Your Excellency's Government will be only too glad to help the planters and it is because I believe that, that I ask that a Committee be appointed to go into the matter fully and report on the subject.

The Hon. the MERCANTILE MEMBER seconded. He said:—This subject has been brought before this Council in years gone by, but the difficulty hitherto has been in finding some method of denaturalising salt. This, as has been pointed out by the hon. mover, has been discovered by a German, and in the pamphlet to which he has referred, full details are given. I have reason to believe that one of the great needs for the cultivation of the coconut in inland districts is a good supply of salt, and, if Government can see their way to adopt the method suggested as an experiment, I think the result will be to afford encouragement to continue. I do not think the revenue will suffer in the least degree. I hope we shall not be told that the stocks of salt are so small that there will be difficulty because that is a difficulty that can be easily got over.

The Hon. the TAMIL MEMBER:—I would add to the Committee the name of the hon. the Government Agent, W.P.

H.E. the LIEUT.-GOVERNOR:—There is no objection whatever on the part of Government to the passing of this resolution, and in proof of that I may state that the subject has been under the consideration of the Government at different times during the last 40 years, and the last

occasion was in May 1889, when a communication was made to a European gentleman, who, I think, has taken up native industries. In that communication he was told that the Government would be quite prepared to consider any proposal which might be made on the part of the agricultural community. I, too, had the advantage of meeting the German professor to whom the hon. member has alluded and he assured me that the system of denaturalisation could be effectively and readily carried out. I was very much assured by what he said and I am very glad that the hon. member has brought the subject to the notice of Government in his motion today. It is now 30 years since the discovery was made but we need not go to Germany for information. Dr. Letheby in 1869 said there was "no substance which can be easily, cheaply and safely used for adulteration. Proper use is only secured by actual ocular supervision." I understand from the German professor that in the progress of science something has now been discovered which is effective and practical. I understand sir, that this is not such a large question as one would suppose at first: In 1888, the last time but one when enquiry was made there were only about 100,000 acres of inland coconut plantations, and the information given to me by coconut planters was that the amount of salt that they would undertake to purchase was 125,000 cwts. for the whole island. I may mention sir, that we have not at present such a very large stock of salt; owing to the season the stocks at some of the stations are very low. I am very glad that the hon. member has included the Auditor-General on the Committee because he is Controllor of the revenue and has always been our authority on the salt revenue. As I have already stated there is no objection on the part of Government to help this Enquiry and I hope it will have a successful issue.

The resolution was unanimously adopted.

PLANTING NOTES.

EXPERIMENTAL FARMING IN MADRAS.—The question of the establishment of experimental farms and farm school is still under the consideration of the Government of Madras, and it is not probable that, if any scheme is ultimately settled, effect can be given to it before the end of next year. The provision of R20,000 made by the Board of Revenue in its Budget estimate for 1898-99 on this account has accordingly been struck out.—*Madras Mail*.

VANILLA AS A CEYLON PRODUCT.—Vanilla, which has hitherto been conspicuous by its absence in the products cultivated in the Island, will soon be included in that category, providing the climate and soil prove favourable. Herr Langa, a young German who came out some time ago to learn tea planting under Mr. Holloway of Franklands, Wattedgama, has purchased an estate of nearly a hundred acres, on which he intends cultivating vanilla, and should he be successful, he will find little difficulty in securing for it a speedy sale in the market for Ceylon products. Vanilla by reason of the agreeable flavour which it imparts to tea and other beverages, is in great demand, though at a premium, and on this account the profits accruing from its cultivation will in time be considerable. Now that the projects has been fairly launched on the somewhat treacherous waters of experiment, it deserves encouragement, and Herr Langa ought to receive hearty co-operation in his endeavour to promote a new industry.—*Local Examiner*.

SALE OF ESTATE PROPERTY IN CEYLON DURING 1897.

We direct attention to the long and interesting list of Sale of Estates in Ceylon during 1897 given on another page. Our mercantile and planting readers cannot fail to scan this detailed series of sales with special attention, and we trust they will give us credit for some little enterprise in presenting the list to them at this early date. There has been little or no abatement during the year now drawing to a close in the formation of limited Companies to take over Ceylon properties, and several of the sales are of groups of estates in different districts associated for the very purpose of starting a Limited Company. This continued activity in the selling and buying market is the more striking when we consider the discouragement offered by lower prices for tea and higher rates of exchange generally prevalent in 1897. Taking the totals realized by the Sales of Estates in our lists as compared with 1896 we have the following:—

Total Value of Plantations sold:			
1896 ..	R5,790,768	..	£1,668,912
1897 ..	3,352,311	..	£1,517,702
Decrease this year		R2,408,457	Decrease .. £ 151,210

CEYLON TEA COMPANIES.

A REVIEW.

We have on several occasions alluded in this column to the steady progress and splendid financial position of Ceylon, which, needless to say, has been brought about solely by the tea planting enterprise. When wonder is expressed that other tropical countries do not enter into the lists of competition against Ceylon by growing tea, the fact appears forgotten that no other country could suddenly open up its land into tea estates as Ceylon planters were able to do within a few years.

The coffee-growing industry had been going on in the island for upwards of forty years before the first break of Ceylon tea was ever shipped to England. During all these forty years jungle had been felled, roads and drains traced and made, and Tamil coolie labour imported, or, indeed, had been raised upon the estates themselves. When, therefore, owing to the ravages of leaf disease and the fall in prices, coffee began to show a recurrent loss to planters who had been long accustomed to a high percentage of profit, the entire island was equipped with nearly all the requirements of a tea-growing country.

In thousands of instances tea plants were put in between the lines of the rapidly-falling coffee trees, so that the weeding which was required for the one product was equally advantageous to the other. The young tea plants also benefited from the shelter and shade furnished by the coffee trees. In hundreds of other instances the coffee trees were boldly removed from whole hill-sides, and either carted away or burnt in the ravines when the denuded portion of the estate was relined, holed, and planted up with tea seedlings, all within the space of two or three months.

Under such circumstances the cost and efficiency of the planting up of 200 acres with tea were such as to defy any competition, while the fact, that Ceylon was equipped with an army of 600,000 Tamil labourers all conversant with the routine and discipline of an estate enabled the new enterprise to be carried on without a hitch. The change of the face of the planting districts was comparable to nothing but a dissolving view. As the coffee trees faded away the tea plants came into focus, until the same dark green aspect was visible over all the hills of the upcountry districts,

GENERAL CRYLON TEA ESTATES.

The history of the tea enterprise of Ceylon has been one continued success, and, although the price of tea may fall, there are no grounds for anticipating any alteration in the good profits now being made by well-opened estates. The company whose prospectus is before us has been formed for the purchase of some twenty-two different properties in various well-known planting districts, and including upwards of 4,000 acres of tea in full bearing, 1,622 acres of young tea, and 3,600 acres of reserve land.

It may therefore be literally said that the company has its capital scattered over a thousand hills, and from the figures and estimates given there is room for a considerable increase in the profits as uniformity of management curtails working expenditure and young tea comes into full-bearing, which it does usually at the end of the sixth year. The estimates contained in the prospectus are based upon the experience of the past ten years by experts who are seldom greatly at fault, and the total amount available for dividend shows that a rate of 10 per cent. may be reasonably expected. A good feature about the company is that the land to be acquired ranges in elevation from what may almost be termed the low country, such as the district of Kalutara, to the elevation of 3,500ft. or 4,000ft. or over in the higher portions of Pussellawa.

With low country teas the planters get quantity, provided the rainfall be sufficient to induce a constant "flush," while for the tea grown in the upper districts they expect a smaller yield per acre, but a considerably higher price in the market. Apart from the share capital the five per cent. Mortgage Debentures should be a good purchase for any investor desirous of having a stake in the tea-growing enterprise and who prefers a fixed rate of interest with specified security for his money.—London *Echo*, December 2.

SALT AND COCONUTS.

We direct special attention to the letter of Mr. Cochran, Chemical Analyst, on this subject. Mr. Cochran seems to prove that it is quite needful to supply salt to the maritime, as well as to the inland, growing coco-palms. The former no doubt benefit by the saline breezes; but at the same time, they make great demands on the soil. Inland trees having no salt-bearing breezes to feed them, make still greater demands on the soil. Altogether, it is evident that our coconut-palm cultivation ought to greatly improve from the liberal application of denaturalised salt. Let us suppose that the result from 200,000 acres being so treated, was an increase of even so few as five nuts per tree per annum, and we should get an addition of between R1,400,000 and R2,100,000 to the annual income of the island. No mean improvement this! The fact is that neither the Government nor the public of Ceylon have ever awakened to a proper sense of the importance and capabilities of the great Coconut Planting Enterprise of the Colony.

THE GALAHA COY.

Considering the difficulties experienced during the past year through high exchange, lower prices for tea and dear rice, we think this new Company has done exceedingly well in paying a total dividend equal to 7 per cent per annum. This has been secured too without neglecting to do the fullest justice to the interests of the shareholders in cultivation, factory and transport improvements. Then the Company has no less than 700 acres of young tea, so that it occupies an exceptionally strong position. The report of the Chairman's (Mr. Strachan's) address and of

the other proceedings appears on page 493, and we now give the main portion of the Directors' Report:—

The Directors have pleasure in submitting their Report, also Statement of Accounts duly audited for the year ending 30th June last.

	£	s.	d.
The gross profit for the season is ..	10,580	15	11
From this has to be deducted—			
Interest on £55,000 Debentures	£2,750		
Dividend on £60,000 Preference Shares at six per cent ..	3,330		
And the Interim Dividend of five per cent on £50,000 Ordinary Shares paid in January	2,500		
	8,640	0	0
			1,940 15 11
London Charges, including Directors' Fees, Trustees' Fees, Income Tax, &c. ..	771	15	5
Leaving a balance of ..	£1,169	0	6
From which the Directors' recommend the payment of a—			
Final Dividend of two per cent. on £50,000 Ordinary Shares, making seven per cent. for the year ..	1,000	0	0
Balance to carry forward ..	£169	0	6

The outturn of the Tea Crop was 829,000 lb., being 5 per cent below the estimate, and the Cardamom Crop was 19,240 lb., being 6 per cent below the estimate. These shortages arose from unfavourable weather during the last two months of the season. The Tea sold at 6'23d per pound nett, or about 3d per pound below, but the Cardamoms realized 10d per pound above the estimate. The unforeseen advance in exchange was an element of loss not calculated upon, as was also the high price of rice, caused by the scarcity in India.

The above causes account for the difference between the estimated and actual result of the season's working, but, considering these adverse circumstances, the Directors cannot but feel satisfied with the result.

During the past year 200 acres of additional land adjoining the Company's estates were acquired, 218 acres were opened for tea, and the expenditure of the season included the sum of £1,418 for manuring, the benefit of which will be felt later on. The factory was extended in a substantial manner in order to deal with the increasing crops, and new lines were built to accommodate the larger labour force necessary for the efficient working of the estates. The capital expenditure has materially raised the value of the Company's properties.

The acreages under cultivation, including 422 acres which are being opened for Tea and Cardamoms this present season, are:—

Tea in full and partial bearing ..	2047	acres.
„ non-bearing ..	727	
	2774	
Cardamoms in full and partial bearing ..	93	
„ non-bearing ..	14	
Timber ..	107	
	276	
Total cultivated acreage ..	3157	
And in addition to this are 1917 acres of Forests, etc., etc. ..	1917	
Making a total of ..	5074	acres

The Tea crop for the current season is estimated by the Ceylon Manager at 1,026,000 lb. against 880,000 lb. for the last season, and the Cardamoms at 27,750 lb. against 20,500 lb. for last season.

The Directors are glad to say that the market has improved, and the sales of present season's Teas to date show an average of 6½d. net per lb. They

take this opportunity of expressing their satisfaction with the work done by the Manager and staff in Ceylon.

CACAO IN CEYLON AND TRINIDAD.

The following paragraph from the London letter of our morning contemporary, is of so startling a character that we reproduce it in full:—

"The following extract from a letter penned by a writer well versed in cacao planting may be found worthy of the consideration of the Cryptogamist who is now called on to prescribe a remedy for the disease under which the trees are suffering:—'What I believe to be the matter with cacao is limit of age, which limit is reached at 13 or 14 years. At any rate cacao dies out, I may say, universally, when it reaches that age. Supplies grow vigorously where the original cacao has died out, so it comes to this, that on a cacao estate you have a certain proportion of acres bearing, a certain proportion dying out, and a certain proportion coming on towards bearing, *i.e.*, if you re-plant as the trees die out, as you should do. When the cacao is sickening before dying it is no doubt attacked by various pests which do not attack it while it is vigorous and healthy. I do not think these pests are the cause of the death of the cacao, although they may hasten it.' If this be a correct view, the practical benefit to be anticipated from Mr. Carruthers' visit will be limited to a slight prolongation of the life of these infirm old patients, though from a scientific point of view his researches into the life history of the fungus may be full of interest." We say the above is "startling" intelligence, because of what is said about the limit of age of cacao. All authorities on the plant and its culture in South America and the West Indies, that we have come across, give a widely different opinion and generally agree with the Dutch writer Berthelink, who, in his monograph on the Cacao in Dutch Guiana, states that no tropical product gives more trouble to the planter, or proves less certain success, up to its tenth or twelfth year, than Cacao; but after that all should be plain sailing, with little or no trouble, and the prospect of steady continuous crops up to a hundred years. The writer further quoted instances of "Cacao Walks"—as plantations are called—in Guiana that had gone on bearing for quite a century. Of course South America is the natural habitat of "Cacao" and the deep rich soil of the Guianas and Amazon valley is no doubt specially favourable; but wherever the plant has been established in fairly good soil in valley "pockets" or in alluvial expanses in Ceylon, we should be confident of a far longer term of productive life than is given by the pessimist quoted above. The risk of disease, such as is now engaging the attention of the Cryptogamist, Mr. Carruthers, must of course be taken into account, apart from soil or situation.

It will be remembered that Mr. R. S. Fraser of Kandnewara and Warriapolla—like Mr. Tytler—before commencing Cacao cultivation in Ceylon, visited Trinidad, and we have just received from that Colony, Proceedings of "The Agricultural Society," which include a very full and valuable Report, giving elaborate analyses of soils and of fruit in all stages from different West Indian Colonies—the two kinds of Cacao dealt with being "Calabacillo" (a new name) and "Forastero." There are more than a dozen pages of analyses alone. In Ceylon we can have no soils to compete with those here detailed. Types of good cacao soils are given for Demerara, Guiana, St. Vincent, Trinidad

and Nicaragua, and we must quote the table with the results obtained, into our *Tropical Agriculturist*. Meantime, it is of interest to learn from the Report:—

From these figures it appears that the cacao tree whilst storing up in the plant itself relatively large proportions of the important elements of plant food present in the soil, requires for the yearly production of young shoots, leaves and fruit not less than 138 lb. of nitrogen, 64 lb. of phosphoric anhydride, 94 lb. of potash, 104 lb. of lime and 31 lb. of magnesia. Under careful conditions of agricultural practice, however, of this great annual drain upon the soil but 87 lb. of nitrogen, 45 lb. of phosphoric anhydride, 37 lb. of potash, 14 lb. of lime and 1 lb. of magnesia are necessarily removed from it, the remainder becoming more or less available again for plant food by the decomposition of the fallen leaves, pruning and husks upon the land. Of the, in round numbers, 130 lb. of nitrogen returned to the soil a considerable proportion, possibly 20 to 30 per cent. may be lost during the decomposition of the vegetable matter, but where the trees are shaded by the nitrogen-collecting Bois Immortel or Oronoque tree (*Erythrina velutina* and *E. umbrosa* which are used on the islands, or *E. glauca* which is used in Guiana) doubtless much of the amount thus lost is recouped to the soil. Hence from these considerations, we are led to the conclusion that a good cacao soil should be one capable of yielding to the tree in the course of years a somewhat high proportion of the important constituents of plant food without exhaustion, and also capable of rapidly rendering again available the large quantities of manurial matter returned to it in the forms of prunings, leaves fallen and broken pods. It must in addition be one in which the course of nitrification readily take place; in other words, a fairly rich friable and well drained soil.

Again, as to manuring, we are told:—

In the absence of direct experiments on the manuring of cacao we have formed our opinion that where the *Erythrina* are used as shade trees, manuring should be directed largely towards the upkeep of the potash and phosphates necessary to enable the shade trees to do their part as nitrogen collectors and that where no shade trees are used the mineral manuring ought to be more largely supplemented by nitrogen. Thus the following mixture or mixtures of other materials yielding the same proportions of nitrogen, phosphates and potash per acre might be advisedly tried on cacao plantations:—

	<i>Erythrina</i> used for shade.	Not shaded.
	cwt.	cwt.
Nitrate of soda ..	1	2
Superphosphate of lime 36 per cent. soluble ..	$\frac{3}{4}$	$\frac{1}{2}$
Potash sulphate ..	1	$\frac{1}{2}$

The materials should be well mixed and applied in quantity according to the number of trees planted per acre around each tree at a distance of about two to three feet from the stem.

But the most interesting portion is the conclusion bearing on "pests," only unfortunately the tree gets little attention—nothing being said of "fungus" or "canker"—as compared with the fruit. We quote in full:—

Pests affecting cacao plantations.—This country being particularly suited over vast areas of its extent for the cultivation of cacao, we availed ourselves of opportunities for investigating some of the ailments that affect both trees and fruit. Two or three species of borers prey on certain trees, but on healthy plantations are not a serious pest, the trees growing under unfavourable conditions of soil, drainage, &c., suffering most from the attacks. Much of the prevalence of these pests is due to the amount of dead brushwood lying about on plantations dropped from the shade trees or left from pruning of the cacao. Plantations kept clear of dead wood would not suffer much. A more serious affection is the fungoid disease to which the fruit is liable and is often attacked with. Fruit so attacked are called by plan

ters "Black" cacao. The fruit is subject to it in many cacao growing countries. The disease as far as we can ascertain is, although present, not very common in this colony. The external signs of an attack of the disease consist of the following: first a minute brownish black spot or spots forms on the outside of the pod as a rule towards the lower part of it but frequently in the middle and occasionally near or at the top. In the majority of cases this first appears at the time when the cacao fruit has attained a considerable size and is approaching its period of ripening. The spot or spots rapidly increase in size producing large patches of a blackish brown colour which appear over the lower part of the pod, in the middle of it or all over the top and if the fruit is allowed to remain on the tree it rapidly becomes black all over and partially rotten.

On opening an affected pod when the disease has somewhat advanced it is found that the pulp surrounding the beans in the immediate vicinity of the blackened part of the husk is slightly discoloured, whilst in the more advanced stages of the attack the whole of the pulp becomes brownish yellow in colour and evolves a characteristic sour and somewhat offensive odour. Later it quite dries up, leaving the beans bare.

Where a diseased pod is in contact with a healthy one the disease in many cases extends to the healthy one. Microscopical examinations of the diseased fruit show that the blackened exterior is occupied by the mycelium of a fungus which gradually makes its way from the husk into the pulp surrounding the beans and finally into the beans themselves. The blackened husks if kept for a short time becomes covered with a light coloured incrustation consisting of vast numbers of the spores of the fungus. We have found that these spores when brought into contact with healthy fruit give rise to the same disease. We have been informed by J. H. Hart, Esq., F.L.S., that this disease or a similar one occurs occasionally in Trinidad but is there not looked upon as serious and is generally ascribed to an excess of moisture. We have recognised the disease as occurring commonly in one of the West Indian islands. It is common and has produced much injury in Surinam, from which colony we have seen and examined pods affected by it.

Analyses were made of diseased pods, and the following gives the composition of the dry matter of the whole fruit of the variety "Forastero" in a healthy and in a diseased state:—

	Healthy.	Diseased.
a. Organic matters ..	95.93	94.43
Phosphoric anhydride..	.81	.59
Sulphuric anhydride ..	.78	.19
Sodium chloride ..	.06	.11
Iron peroxide ..	.05	.04
Manganese oxide ..	traces.	.01
Calcium oxide ..	.22	.27
Magnesium oxide ..	.65	.59
Potassium oxide ..	2.03	2.85
Sodium oxide ..	.03	.40
Silica ..	.04	.58
	100.00	99.98

Taking into consideration that the healthy fruits analysed were quite ripe whilst the diseased ones had only attained about two-thirds of their normal development, the variations in the analytical figures have but little significance. As the contents of nitrogen and of the mineral constituents derived from the soil varied but little in the two cases, probably the prevalence of black cacao in any place is not connected with defects in the composition of the soil. Wherever we have seen it occurring the diseased condition has appeared to be closely connected with an undrained condition of the soil or with dampness resulting from over-shading and over-crowding the trees. We consider that the remedial treatment consists in the proper drainage of the soil and judicious pruning of both the cacao and shelter trees to let

in light and air. All affected pods should be separated from the apparently healthy ones, broken at a distance from the trees and the husks either burnt or else treated in heaps with quick lime and covered with soil. As an alternative the husks might be treated with a solution of half a pound of sulphate of iron (green vitriol) to one gallon of water or with Bordeaux mixture, but we are satisfied that the destruction of the pods by burning is the most effective process.

When trees are at all badly affected it may be advisable to spray them with Bordeaux mixture prepared in the following manner:—Dissolve six pounds of copper sulphate (blue vitriol) by suspending it in a coarse cloth bag near the surface in four gallons of water contained in a wooden or earthen vessel. Slake six pounds of quick lime (do not use air slaked or agricultural lime) in four gallons of water; mix the two and when thoroughly mixed, insert into the liquid the freshly polished blade of a knife and leave for a few minutes. If the blade then shows a coppery discolouration more lime must be added until upon immersion it ceases to do so. Dilute the mixture with water to about 40 or 45 gallons.

We give this receipt as the mixture may be found efficacious in fungoid diseases of fruit and other crops of which the smuts so common on mango and orange trees may be mentioned as instances.

There is nothing here to help us in regard to the subject of Mr. Carruthers' investigation; but all through the Report under review, a great deal is made of "judicious pruning." But we do not think that Ceylon cacao planters have failed of their duty in respect of any one of these particulars.

OUR MAP OF THE PLANTING DISTRICTS OF CEYLON.

A FEW OF THE TESTIMONIALS RECEIVED.

H. E. THE GOVERNOR.

His Excellency desires me to convey to you his thanks for your new Map of the Planting Districts, which will be most useful. It is in fact just the sort of thing we have been wanting for some time.—Yours truly,

R. WARD JACKSON.

The Queen's House, Colombo, 7th Dec. 1897.

FROM AN OLD SUBSCRIBER.

I must send you a few lines to wish you a merry Christmas, and thank you for the new map of the Estates: its arrival has been one of the events of the week. Long-looked-for, come at last. Although I don't know all the districts, and am therefore no authority on the geography of Ceylon estates, yet so far as I do know, I think it is beautifully done and wonderfully accurate. The marvel is that you have been able to produce so useful a map of the planting districts and, issue it at the low figure fixed. One would think that you expected to sell them by the thousand before they could pay you for the trouble and cost you must have let yourself in for, to produce such a map. For my own part I thank you very much for undertaking the work, and congratulate you on the result, and hope it may prove, as it deserves to be, financially a success.—Yours faithfully,

A SUBSCRIBER.

Matale N.E., 26th Dec. 1897,

FROM "TIMES OF CEYLON," DEC. 15TH.

We have to acknowledge receipt from the Observer Office of a new large map of the Planting Districts of Ceylon, brought up to date, and such as planters and others have long needed. The map, which

is on a scale of three miles to an inch—with a small map in the corner for speedy reference—shows principal roads, railways completed, railway stations, resthouses, boundaries of provinces “pearl stations,” and gem and gold districts, and most useful of all, the estates in the new and old planting districts. These include, besides the former and better-known coffee districts, the new ones that have been, and are still, springing up in the low-country, such as the Kurunegala district—where the extension of tea and coconut cultivation during the last few years has been wonderful,—the Panadura and Kolutara districts, the Veyangoda estates, the Morawak Korle extensions, and the estates scattered throughout the Southern Province at Udagama, Ambalangoda, and near Galle. The publishers certainly deserve credit for their work.

FROM THE “CEYLON EXAMINER,” DEC. 15.

With characteristic zeal in everything likely to advance the planting interests of the Island, Messrs. A. M. and J. Ferguson of the *Ceylon Observer*, have just published a splendid map of the Planting Districts of Ceylon, showing the position of the principal Tea, Cacao and Coffee Estates in the country. The scale of the Map, 8 miles to the inch, has enabled its projector to delineate the natural features of the districts exploited for planting purposes, in a clear and comprehensive style. The Map cannot but be therefore, of the highest value to intending prospectors in search of suitable localities for cultivating the staple products that already form the objects of agricultural enterprise, or for the introduction of new ones for which peculiar conditions in regard to altitude, situation and so forth are essential. The range of country exhibited is from the Nalande Oya north of the Matale District to Ambalata in the South in the vicinity of Hambantota, and from the West Coast of Ceylon to Monaragala District in the East. Each Planting District is distinguished by colour as well as by name, and to the ordinary traveller the inclusion of Principal Roads, Railways completed, Railway Stations, and Resthouses must prove of no small utility. A printed list of all the Tea Districts with the altitude of each forms part of the contents, while a smaller map on the same sheet in which is marked the Gem Districts, Pearl Oyster Stations, and the places where gold has been traced, will no doubt be of service to the mineralogist and the scientific explorer.

FROM THE “CEYLON INDEPENDENT,” DEC. 17.

Messrs. A. M. & J. Ferguson of the *Ceylon Observer* have placed both the planting and mercantile community of Ceylon, it may be added the general public as well, under a considerable debt of obligation by their publication for the first time of an up-to-date map of the Planting Districts of Ceylon showing in a clear and accurate manner the position of all the tea, cacao, cardamom and coffee estates in the Island. A reliable map of this description has long been a desideratum and we had a guarantee that if Messrs. A. M. & J. Ferguson undertook the work they would do it thoroughly and turn out something that would reflect credit upon their enterprise, but we confess that the excellent result achieved surprises us. It has been a colossal task, but the preparers have not shrunk from the difficulties in their path, rendered all the more acute by the rapid development that has gone on and is continuing to this day. We can well believe that every effort has

been made to secure reliable information and we can only find words of unstinted praise at the skilful way such information has been utilised. The size of the map is 48 inches by 36 inches, and on it the position of nearly 1,600 estates can with ease be located. It makes an invaluable reference and should form an indispensable ornament in every bungalow and mercantile office in the Colony. The proprietors hope to make it the basis of a series of maps which “issued from time to time will prove useful records of the progress of Tea Planting in Ceylon.” The map is arranged on a scale of three miles to the inch and the principal roads, railways with stations and the resthouses are equally clearly defined. There is also a list of the altitude of the various planting districts, and a small key map of the Island of Ceylon showing the gem districts, pearl oyster stations and the places where gold has been traced. The work was lithographed by Messrs. Standidge & Co., Ltd., of Old Jewry at their extensive works in Worship-street Finsbury, and the proprietors accord ungrudging testimony to the care and efficiency with which this part of the labour has been carried out.

“CATHOLIC MESSENGER,” DEC. 18.

We received from the *Observer's* Office a new large map of the Planting Districts of Ceylon, which will be very useful to all the Planters. The map which is on a scale of 3 miles to an inch, with a small map in the corner for speedy reference, shows principal roads, railways completed, railway stations, resthouses, boundaries of provinces, pearl stations, gem and gold districts and, most useful of all, the estates of the new and old planting districts. On this map are marked also the new estates that have been, and are still, springing up in the lowcountry, such as the Kurunegala, Panadura, Kalutara districts, the Veyangoda estates, the Morawak Korle extension, and the estates scattered throughout the Southern Province at Udagama, Ambalangoda and near Galle. This useful map, will no doubt, find a ready sale among the Planters.

“MADRAS MAIL,” DEC. 20.

Messrs. A. M. & J. Ferguson, Proprietors of the *Ceylon Observer*, have just published a very fine map of the Planting Districts of Ceylon, showing the position of the principal Tea, Cacao and Coffee estates. The scale of the map is three miles to an inch, and various simple devices, marginally noted, are used to indicate principal roads, railways completed, railway stations, rest houses and boundaries. The various districts are distinguished by colours as well as by name. To the right of the map is given a list and altitude of tea planting districts, some fifty in number, while in the left hand corner is a small map of the Island in which are shown the gem districts, the pearl stations and the gold producing tracts. The map is likely to prove most useful to the colonists and reflects great credit on Messrs. Standidge & Co., Lithographers of Old Jewry, London, who produced it.

AMSTERDAM CINCHONA SALES.

Our Amsterdam correspondent telegraphs on Thursday evening (Dec. 9th.) that of the 8,842 packages of Java cinchona offered as today's public sales only 4,889 packages sold, at an average unit for the Manufacturing bark of 7c. per half-kilo (equal to 1½ per lb.) against 7.90c. paid at the auctions on November 4. Today's sale has therefore resulted in a decline of about 12 per cent, the general tone throughout being dull

and with a downward tendency. The American and English manufacturers bought 5,372 kilos; the Auerbach factory, 2,618 kilos; the Brunswick factory 5,069 kilos; Mannheim and Amsterdam factories 1,552 kilos; Frankfort and Stuttgart factories 2,421 kilos; various other buyers 4,921 kilos. The prices realised for Manufacturing bark ranged from 10½c. to 60½c. (equal to 2d to 12d per lb.) and for Druggists' barks from 10c. to 99c. (equal to 1 3-8th d. to 1s 6d per lb.)—*Chemist and Druggist.*

THE AMSTERDAM DRUG-MARKET.

Our Amsterdam correspondent writes, under date of December 8, that the Cinchona market remains firm, everybody anxiously awaiting the result of the heavy auctions (equaling 40,793 kilos sulphate of quinine) on December 9. Quinine shows no change, business in this article being very restricted. There has been rather more speculative demand for Cubebs, and offer of 12c. per half-kilo have been refused for fair bold berries. But the stock, both in first and second hands is very heavy. A parcel of 186 kilos of Java Vanilla has been sold by tender at a secret price. The lot was valued at from 6f. to 10f per half-kilo. There has been some trade in Java Cannaga oil, of which about 100 bottles have been taken by dealers. The present value of good quality is about 7-50f. per bottle. Cassia fistula in pods is somewhat lower. About 200 baskets have lately been sold, but the price has not been made public.—*Chemist and Druggist.*

THE SCHOOL OF AGRICULTURE IN 1897.

During the past year the School of Agriculture has been the subject of much criticism. Owing to the lack of encouragement on the part of Government and the reorganization of the Technical School as a Training College for employees in the various scientific departments of the Colony, the numbers of students in the School of Agricultural fell considerably. This state of affairs gave rise to a good deal of comment, some going the length of advocating the suppression of agricultural education, but the large majority rightly demanding the reorganization of the institution on a more liberal scale. The school has undoubtedly been neglected by the State and given small opportunity for carrying on the useful work which is expected of it owing to a want of funds and any kind of support from Government. It has been officially announced that a Commission is at present dealing with the school, and the result, if the interests of the Colony be consulted, should be that the institution will be set on a proper footing with wider scope for doing the good work which it is capable of doing. The School of Forestry for training students for the Forest Department has proved a useful adjunct to the Agricultural School and now supplies the necessary technical education, which was much required for employees in the Forest Department.

The Veterinary Surgeon attached to the School has been given an Assistant who is stationed in the N.C. Province, and between these two officers some progress has been made towards the suppression of cattle disease in the Island.

The Government Dairy has proved an unqualified success both as a source of revenue to Government and as an agent in the improvement of the indigenous breeds of cattle in Ceylon.

OUR COMMERCE FOR 1897.

(Special Report by a European Merchant.)

Although returns for the year will not be completed till some time in January, yet those figures which are available now are complete to a point

sufficient to draw fairly accurate comparisons with those for 1896:—

A. EXPORTS.

1.—COFFEE.—In 1896 Ceylon exported	22,747 cwt.
„ 1897 „ exports not likely to exceed	19,250 „
showing a falling-off, of	3,497 „
2.—CINCHONA.—In 1896 Ceylon exported	1,309,560 lb.
„ 1897 Ceylon exports not likely to exceed	650,000 „
showing a falling-off, of	659,560 „
A temporary increase in export of this bark might be looked for in 1898, as prices in London are dearer by 100 per cent than what they were about this time in 1895.	
3.—TEA.—In 1896 Ceylon exported over	108,000,000 lb.
„ 1897 Ceylon exports not likely to exceed	114,500,000 „
showing an increase of	6,500,000 „
4.—COCOA.—In 1896 Ceylon exported a little over	31,000 cwt.
„ 1897 Ceylon exports expected to amount to	35,000 „
showing an increase of	4,000 „
Market for cocoa steadily improved during the last six months of this year.	
5.—CARDAMOMS.—In 1896 Ceylon exported a little over	452,000 lb.
„ 1897 Ceylon exports will, it is thought, exceed	515,000 „
showing an increase of	63,000 „
Prices for cardamoms show a sharp decline as the year closes, but for most of the year prices have been exceptionally good.	
6.—CINNAMON.—In 1897 exports of quills and chips considerably exceed these for 1896, and prices have gone back quite 1d per lb. both in Europe and locally, during the closing months of the year.	
7.—COCONUT OIL.—In 1896 Ceylon exported a little over	343,000 cwt.
„ 1897 Ceylon export is expected to exceed	410,000 „
showing an increase of	67,000 „
Exports of oil to India in 1897 are double those of 1896. Exports to the Straits also show a large increase in 1897. Rupee values have not fluctuated violently during the year.	
8.—COPRA.—In 1896 Ceylon exported a little over	50,000 cwt.
„ 1897 Ceylon exports will probably aggregate	107,500 „
showing an increase of	57,500 „
The large increase in export of copra this year is almost entirely due to a strong demand from Hamburg, where other copras were in smaller supply than usual.	
9.—DESICCATED COCONUT is expected to show an increase in quantity exported, of 12½ per cent over 1896. Prices unfortunately for this industry remain at a very low figure.	
10.—PLUMBAGO.—Exports for 1897 will show a slight increase over those for 1896. Prices during 1897 have ruled higher all through than for many years past, and owners of pits must have made good profits. The market closes very firm and dear prices seem likely to rule for some time.	
11.—COCONUTS.—Exports this year will be much about the same as for 1896.	
12.—COIR GOODS, ROPE, YARN AND FIBRE all will show an important increase, but Yarn and Fibre especially so.	
13.—EBONY AND SAPANWOOD, both will show a large decrease.	
14.—PALMYRA FIBRE AND KITUL FIBRE will also show a falling-off.	

B. IMPORTS.

RICE.—The price of rice during the year ruled very high, gradually increasing from January till August, when it was dearest. Since then prices have been easier, and as the year closes good Kumway is obtainable at R3-80 per bushel in Colombo.

DRY GOODS.—Imports of Manchester and Continenta goods have been considerable. Exchange has been favourable to importers; and as the year closes with high exchange, dry goods may be expected to arrive on a fairly large scale during the first half of 1898, and supplies will be ample for all demands.

Business was to some extent impeded during the latter half of this year owing to the slip on the Railway line. In anticipation of "Tivali" demand, upcountry dealers who came to Colombo for supplies, had in many instances to return without these—being unable to get them up in time for Tivali—thus to some extent a market was lost. The small cash balances due to coolies after deductions for rice have also tended to curtail the offtake.

ESTATE REQUISITES have on the average ruled low in price.

METALS have been imported in fair supplies.

HABERDASHERY GOODS.—A fair business has been done during the year.

C. SHIPPING.

With the exception of the closing part of the year, tonnage has been ample and on the average freights ruled low. Increased facilities for loading and unloading at the wharf and jetties are urgently needed to expedite the despatch of steamers. The quantities discharged from and loaded into steamers—taken per hour of continuous work—compare unfavourably with former years.

REVIEW OF THE GENERAL NATIVE TRADE 1899.

(By a Sinhalese Trader.)

The native trade in the Pettah during the past year, has been looking up, in spite of prices fluctuating, consequent on the rise and fall in the value of our rupee. Luckily for importers of European goods, exchange rose opportunely, which enabled all Christmas goods to be placed at a reasonable value. A glance at the Main Street shops will convince one, that importations have been heavier than previous years. Some shops show better quality for instance in Drapery and Millinery, F. X. Perera's have kept up their usual reputation for good quality, fair value, and politeness.—"The Diamond Jubilee Warehouse" which was opened during the celebrations of Her Majesty's Diamond Reign is dressed in good style. Abdul Carrim also deserves mention for his usual display of superior goods, especially in Millinery and Drapery, and last, but not least, "The Pettah Cash Drapery Warehouse" owned by the general N. S. F. established in 1893, though still in its infancy, has done well in following in the wake of her elder English sister—all goods imported being of superior quality and finish.

SPIRITS AND WINES business has been brisk in good brands, but the market is glutted with spurious inferior rubbish which ought to be prohibited by the City Fathers.

OILMANSTORES.—Trade in this line has shown up well. Importations have been heavy. Australian Produce is making headway. Germany is still pushing her biscuits, dealers looking to cheapness rather than quality. Special mention may be made of A. Simon Fernando as being the largest wholesale dealer and Cornelius Fernando and Sons may be reckoned the largest retailers. Messrs. V. P. Perera and Sons, who established themselves about 32 years ago, have unfortunately collapsed; some attribute failure to recent bad management.

LAMPWARE, GLASSWARE, HARDWARE, CEMENT, OILS PAINTS &c., did a very big business during the year,

at steady rates, caused by increased demands for building purposes. Germany has held her own in nearly all the above lines.

PAPER, PATENT MEDICINES AND DRUGS' TRADE.—In these lines have been very favourable, Stearn's Wines Scott's Emulsion, &c, making good headway. But the line, which showed the greatest activity, and assumed large proportions, was Paper of all descriptions. Here again German makes, especially in printings and coloreds found great favor. Sorry to find that the Indian Paper Mills have fallen off considerably during the year. The Baly Mills were offering stocks on hand at cutting prices, but very little changed hands.

CHINESE AND JAPAN goods: transactions were much restricted, a little passed in Canton matting. Paper lanterns were in great demand during the Jubilee, but importations fell far short of demands. Fire crackers came into the market in large quantities and found good sale.

INDIAN PRODUCTS, RICE.—The demand during the year has been larger than ever, rates fluctuated daily for all kinds except Rangoon raw rice which was rather sluggish, owing to abundant supplies. Business done during the year was very steady. The Chetty firms almost monopolising the trade. Prices ran up to R6 per bushel for Muttusamba. Supplies were up to demands. The high prices ruling may be attributed to short crops caused by long drought throughout India.

CASTOR OIL, CASTOR CAKE, FISH MANURE, AND CATTLE BONES: next to Grain these form a very important importation, large business has been done with European Firms at steady prices, the trade being almost monopolised by the Tuticorin Tamils.

SUGAR.—Importations were heavy during the year, demands for the middle grades were great, but importations were restricted owing to European importations, German Granulated crushed has held the market firmly and bids fair to maintain its present position. Importations have been heavier than ever of the latter grade.

KEROSENE OIL.—Messrs. Carimjee Jafferjee are monopolising the trade in oil. "Daylight" as usual found most favor, "Sumatra" bids fair to do good business. The largest consumption has been in Russian Tank Oil.

GRAIN, COTTON SEED, &c.—These did a free sale as usual in spite of the heavy prices that ruled.

DRY FISH AND MALDIVE FISH: rates have been fully maintained and the bulk of the business in the former is in the hands of the Tuticorin Tamils. In the latter article the trade is almost entirely in the hands of Messrs. Carimjee Jafferjee, the Bombay merchants, who have the Maldivians sellers well in hand; shipments arriving in their own schooners. The demand was great, stocks plentiful. Prices exorbitant; a month or two ago rates ran up to R45. About four years ago Maldivian fish was sold at R14-50 per cwt. Monopoly is the only reason one can give for this unjustifiable raising of prices.

BOMBAY AND CALCUTTA FLOUR.—The Bombay Flour Mill Co.'s brands were to the front, landings heavy and the trade satisfactory: but the Plague having broken out in Bombay, direct arrivals were nearly nil. The Bengal Flour Mills Co., did a fair trade. Importations from the former Company are now coming in freely and good business is being done in their brands.

SUNDRY INDIAN PRODUCE CURRY STUFFS, &c.—There was keen competition in these, but prices have been maintained. Chillies ruled at unheard-of prices, and Shellots or Red Onions were ditto.

EXPORTS.—Leading native firms did good business in Ceylon Produce, heavy consignments of Coconuts, Coconut Oil, Desiccated Coconuts, and a little Tea, Plumbago, &c., have been shipped to England and the Continent, Madras, Calcutta, Coconada and Singapore drew large shipments of oil.

NATIVE JOURNALISM.—Success is still crowning the printers at Pettah. "SriLankodaya," another native journal, has come into existence during the year under review, and one or two other magazines,

Sale of Ceylon Plantations (Tea and Coconut) during 1897.

<i>District.</i>	<i>Name of Estate.</i>	<i>Name of Purchaser.</i>	<i>Amount.</i>

CEYLON GAME PROTECTION SOCIETY.

A local meeting was held at K. C. C. on Nov. 29th, when there were present:—Messrs. J. A. Maitland (in the chair), H. C. Richmond, T. C. Robin, E. T. Clarke, M. E. Waddilove, W. Ormiston, W. G. Powell, J. Marks, R. D. Carson, A. P. Tucker, W. F. Reid, H. M. Wilson, L. R. Biddell, and T. R. Barkley, hon. secretary, *pro. tem.*

The Secretary read letter from Mr. Farr, expressing his regret at being unable to attend the meeting.

It was proposed by Mr. CARSON and seconded by Mr. ORMISTON.—That a local branch of the Game Protection Society be hereby formed, under the rules and affiliated to, the main society.—Carried.

It was proposed by Mr. BARKLEY, and seconded by Mr. WADDILOVE that Mr. Ormiston act as hon. secretary.—Carried

A committee was then formed consisting of Messrs. R. D. Carson, H. M. Philby, J. J. Robinson, J. R. Barkley, E. de Winton, W. Hermon, H. O. Hoseason, C. de Winton, J. H. Carson, A. G. Dupuis, and W. Ormiston, (Hon. Secretary.)

Mr. ORMISTON then rose to point out that in the Uva Province, the closed season might be cut short; it now ran from May 1st to October 30th. The only reason for a closed season in Uva was to prevent the slaughter of game while drinking at rivers during the dry weather, and he pointed out that the months of May and September were usually wet months and would not easily lend themselves to the poaching proclivities of the native. He would therefore propose that Government be asked to alter the closed season in Uva from the 1st June to 3rd September. This was seconded by Mr. ROBIN.—Carried.

The next subject taken up by the meeting was the possession of fresh deer meat and hides during the closed season. Most of the members present had seen natives with meat in their possession, but it would seem that this was insufficient to obtain a conviction. It was understood that the poacher had to be caught *in flagrante delicto*, which was almost impossible; it was therefore proposed by Mr. Biddell and seconded by Mr. Clarke.—“That possession of fresh deer meat or hides during the closed season be made

a penal offence, and that Government be respectfully asked to alter the Game Ordinance accordingly.”

It was then proposed by Mr. MAITLAND and seconded by Mr. MURRIE WILSON:—“That the Government Agent of Uva be asked to issue orders to the various headmen and forest watchers of the Province to be more vigilant and in every way in their power to assist the Game Protection Society in preventing the present wholesale slaughter of deer during the closed season, the local branch of this society agreeing to pay a reward of R20 for each conviction.”

A lengthy discussion here ensued and it transpired that it was a well-known fact that there was a large illicit export of horns and hides from the Southern coast, and it was believed that the light-houses aided this smuggling. It was thought expedient to enlighten the authorities on this subject and to ask the hearty co-operation of the Trinity House and port officials of Southern India in the matter.

It was unanimously carried that a cordial vote of thanks be tendered to Mr. Thomas Farr for his untiring energy in furthering the interests of the Game Protection Society.

The meeting here adjourned.

J. R. BARKLEY, Hon. Secy. *pro. tem*

CEYLON CINNAMON.

Mr. Ernest Williams offers in the “Windsor” amusing indictment of the Christmas pudding. It is consecrated to John Bull, and yet most of its ingredients are foreign, Greek currants, American plums, candied peel from everywhere, French brandy! The only comfort for Mr. Williams is that the cinnamon comes from Ceylon, and Ceylon is still part of the British Empire, though you can never be sure that when you open a Tory evening paper you will not find a suggestion that Lord Salisbury is thinking of making a present of Ceylon to France. However, it is plain now that patriots cannot eat their Christmas pudding any more and we expect to hear that it has been banished from Mr. Chamberlain’s household.—London *Daily Chronicle*.

Correspondence

To the Editor.

CEYLON GAME PROTECTION SOCIETY.

Dec. 1st.

SIR,—I have the pleasure to forward for publication in your columns, if you will be good enough to oblige me—a copy of the Report of a local meeting of the Game Protection Society held in Haputale on Nov. 20th. It is most gratifying to me to welcome this new departure, and I trust the example of Uva will be followed by other districts in Ceylon.

If only some enthusiastic Sportsman in each district would take up the matter of Game Protection in the same wholehearted way that Mr. Barkley has done, I am confident that real and lasting progress would be made.

I take this opportunity of recording my thanks to Mr. H. V. Bagot of Hewaheta, for his hearty co-operation.—I am, Sir, yours &c,

THOS. FARR, Hon. Secy.

[The report of the meeting referred to will be found on page 505.—ED. T.A.]

TEA CULTIVATION: PRACTICAL
PLANTERS ON "FORKING," "DRAINS"
AND THE "PREVENTION OF WASH."

Pundalnoya, Dec. 17.

SIR,—I am pleased to see "Veteran," (see page 476) drawing attention to the fact that forking on steep land does not engender wash, if carried out as he describes, namely, by loosening the soil without turning it over. I am prepared to go further and assert that it is actually preventive of wash. The chief cause of wash is the inability of the rain water to penetrate the ground fast enough when the surface soil is firm and close. Directly the soil is loosened by the proper use of the fork, the rain will soak in as it falls, and there will be no accumulation of surface water to rush down the slopes transporting valuable soil in his progress. The plants also will benefit by the well-known valuable properties of rain water and by the more perfect aeration of the soil.

"Veteran" also touches upon the question of filling up drains to avoid some of the effects of drought, which, it is thought, might follow the breaking-up of the surface soil. But when the rain water has been allowed to penetrate to the subsoil, instead of being hurried off into the nearest ravine, I think it will be found that the tea plant—with its deep roots—will feel the effects of drought much less.

In connection with both the prevention of wash and the closing of drains, I would draw attention to another plan that I have been lately adopting and which has so far proved most satisfactory. This is, to fill up all the drains evenly with the prunings immediately after a field has been pruned. Paradoxical as it may seem, this really prevents the disastrous blocking of drains that so often occurs during a heavy plump of rain. There can be no accidental heading back of water. Any solid matter that falls into the drain rests where it falls—above the prunings, and is not carried along to form a dam at the first obstruction. The water filters through the rubbish, depositing any soil it has

brought down, and trickles slowly away below, much of it finding its way into the subsoil. The repeated clearing out of drains is no safeguard against a block—as I have often found to my cost. The cleanest drain is at the mercy of the first rock that rolls down the hill.

I plead the following advantages for my method:—

1. The saving of soil: the water being filtered in its passage through the rubbish.

2. A great saving in expense: there being no necessity to clear out the drain until the time for the next pruning, when the accumulated soil and decayed vegetable matter will be spread over the surface below the drain, and the drain will be recharged with the new prunings.

3. The avoidance of any accidental block at one spot, with its consequent leading back of water and overflow.

4. Benefit to the tea by the freer percolation of water in its slower flow along the drain; and by the application of accumulated soil and humus.

5.—The convenient disposal of the troublesome prunings.—I am, sir, yours truly,

E. ERNEST GREEN.

THE CACAO DISEASE.

Dec. 16.

DEAR SIR,—As the investigation into the Cacao disease may benefit all growers of that product, and as it would be unfair that the cost of it should be borne by a few, I think that, as in the case of work done for the benefit of the Tea Industry, it should be met by an extra export tax on that product, to be levied till the account is closed.

This, at the rate of 25c per cwt., would probably take only one year.

Hoping you will give room to my suggestion,—I am, yours truly,

A. V. D. P.

[A very fair suggestion.—ED. T.A.]

TEA CULTURE AND THE RISK OF
APPLYING CERTAIN MANURES.

Colombo, 22nd Dec.

DEAR SIR,—With reference to your comments passed in Monday's issue of your paper on the question of tainting of the flavour of tea by the application of strong smelling manures, like blood or fish, it would read as if the chief argument of Mr. John Hughes against their use was in this direction, whilst on the contrary his principal objection against them—and raw bones—was on the ground of the risk of introducing some fungoid disease.

Mr. John Hughes laid special stress on this point and declared the use of these substances as "dangerous," unless treated with acid before their application.

The immense damage done by the Coffee leaf-disease, and more recently by the Cacao disease, whether due to the above cause or not, should certainly be a warning to planters not to treat this matter lightly, and in their own interest try to avoid any such risks—prevention in all cases being better than cure.

As regards the question of strong-smelling substances tainting the flavour of tea I would point out that I had been cautioned against their use by more than one authority on this matter, and as a practical demonstration one of the leading agronomists of France submitted to me samples of wine from a vineyard, which

had been manured with a strong-smelling fertiliser, and the flavour of which had been distinctly affected, whilst the wine from the unmanufactured plot of the same vineyard was all right.—Yours truly,
A. BAUR,
The Ceylon Manure Works.

ESTATE SUPERINTENDENTS AND PROPRIETORS.

SIR,—How is it you have never given us your views on the question of treatment of Superintendents and all Tea Planters by Proprietors? Further reference to it seems desirable as some practical good may result from adequate ventilation of the matter. As a contemporary of yours once pointed out, the only difference—a very material one too—in which way employers treat their Superintendents and Assistants is, that the one is recognized as a fellow human being, toiling in a trying and dangerous climate to make capital bring in its largest return to the owner and the other is considered simply as a machine, to be used as long as it can go and then to be cast aside! Awaiting your opinion.—I am, yours truly,

GREATLY INTERESTED.

GEM DIGGING AND GOLD PROSPECTING IN CEYLON.

SIR,—Will you kindly allow me for the second time a little room in your valuable columns for the benefit of your readers who may be interested in this special industry in the island.

I have read with interest some paragraphs which appeared in the local "Times" a few days ago. I agree with the explanations given by the writer, as regards the oriental amethyst (the *ulakanthiya* of the natives) which is a mixture of the red and blue colour in the same stone. When the ruby colour is predominant the stone is subjected to fire and in most of the cases the blue colour will disappear, leaving a first-class ruby, but when the blue colour is in excess no attempt is made to subject it to the fire and it is cut as it is and takes the name of the oriental amethyst. The real Ceylon amethyst is the best specimen I have ever seen. Certainly Lockhart's Gem Separator will not retain it as the specific gravity is very low. Even with the present system of washing if the water is muddy when the washer can't see its sparkling colour, in many instances it is lost, as this gem will not settle down under the gravel where the other gems separate from the rubbish. The amethysts, which are produced in Mexico and Brazil can't approach the Ceylon specimens. Up to date there has not been discovered any gemmiferous primitive soil or matrix from which the gems are disintegrated. Therefore gemming is carried on only where the deposits of alluvial soil hides the deposit of gravel where gems are supposed to be. This kind of gravel or strata is found at different depths, depending especially upon the size of the water-course. When digging near a river at a depth of about 90 feet, I came across two or three strata of illan one over the other. The two upper ones showed no signs of gems, but gems and gold I found in the last one, that is to say the gravel resting on the malava, as it is called by the gemmers, or the primitive soil of the English. Therefore to wash all the alluvial silt which covers the gravel seems to me to be absurd. I admit that a gem may have been picked up by a cooly woman in Rangwalatene estate without any signs of illan. When the island came out from under the waters and before the vegetation took place, naturally the earth was naked. Therefore the water could easily wash the earth carrying with it all that it contained. In these days also handships were more frequent and in large masses and where the waters found space there they left

it, so the present alluvial deposits which now we come across are of primitive formation. Then when the earth covered herself with vegetation the water could no more wash easily the soil of the highest mountains so it is not easy to find gems in recent deposits.

After the opening of so many estates in the island and the land being bare and naked again it will not be strange to find a gem on the surface of the earth without any signs of illan. The gem being naturally disintegrated from her matrix by the action of the water and remaining there unprotected, on the surface, anyone could have picked it up; this has happened many times on upcountry estates.

As to gold the writer says in his letter of the 17th inst., that gold has been found in the illan of gem pits in specks up to the size of half grains of rice. Gold has been found by myself a great deal larger than that size. At a place called Deturangalla three miles this side of Morawaka, gold nuggets were found of ten penny-weights and larger.

Another well-known European and I went prospecting there and we could not trace the matrix from which the gold had been disintegrated. I hope as the writer says that Mr. Lockhart's Separator may locate it in the bottom of the machine, but it cannot point out the reef.

There is another trouble which the Gem Separator will find on the way, that is, that the alluvial soil of the island contains a large quantity of perioxides of manganese which will fill up the receiver in no time, so there will be little or no space left for the gems, especially the large ones which remain at the very top of the *Kalu-wella*. There is another place well-known to me where I found gold dust and pepitas, better than the last-named place. I am sure that some startling things will be found—things which will surprise not only the aforesaid writer but the inhabitants of the island.

At the time of the gold prospecting fever in Ceylon I applied to Government for assistance, but it was refused. As my means could not afford the prospecting expenses the matter died a natural death; but, if God spare my life and provide me with the means to go and prospect the place at my own expense, I will not leave a spot unsearched for the precious metal. If this trial is not allowed to me the secret will pass to my heir.—Yours faithfully,

A. DE DOMINICO.

GOLD IN UVA.

DEAR SIR,—I have read with interest your leader on "Mining and Gemming in Ceylon." I would certainly endorse Mr. Haly's opinion, that the quarts and localities at the foot of the hills below Nanunnkula Kanda should be searched and examined by Mr. C. Tottenham's friend Capt. Tregay; there is a village called "*Rang-denia*" reputed in ancient times as being a city of gems and gold in such abundance that the very plough shares of the villagers, were made of gold! (see a book called "*Wagarupota*" belonging to Tel-denia R.M.) Near Wellawaya there is the site of an old ruin (temple or dagoba), with a rock inscription recording the existence in ancient times of a fabulous wealthy city and country whose inhabitants died of plague or famine; and that all their goods and chattels, *golden ploughshares* and all, were buried underneath this ruin and rock inscription. Some years ago, I got from the villagers near about this locality some ancient coins in gold and copper, and many other persons are said to have found lots of jewelry; I am of opinion that gold may be found in this locality if a search be made.

As for iron: I remember Dr. Gygax, the geologist in June 1858, was at Biluhuloya on his exploring expedition, and he reported that iron of a very superior quality existed between Ratnapura

and Hapatule; iron used to be smelted in holes and kilns on the patnas by villagers near Kaha-galla when I came in '58. The rough lumps of iron were taken to Ratnapura and they came back to us in the shape of catties and axes for felling our forests, and mamoties for the villagers ploughing season, besides gun-barrels and many other kinds of im- plements. I think Dr. Gyax said the ironstone contained 90 per cent of pure iron. What we want is coal to melt it.—Yours truly,

OLD HAND.

SALT IN THE ASH OF COCONUT HUSK.

Kandy, Dec. 27.

DEAR SIR,—Some time ago I sent you the results of an analysis of the ash of the husk of a coco- nut grown near the sea. The analysis shewed that the ashes contained a large proportion of chlorides, the total chlorine found being 24·80 per cent, equivalent to 40·87 per cent of common salt. The inference from the analysis was that common salt should be regarded as an essential ingredient of plant food of the coconut tree; but to make certain that a large amount of chloride was nor- mally present in the ash of coconut husk, and that this was not simply an accidental circumstance due to the proximity of the tree to the sea, it seemed to be necessary to prove by experiment that salt was also present in large proportion in the ash of husks of nuts of good quality grown far from the sea. A short time ago I had the oppor- tunity of demonstrating this in the case of a well- grown coconut, much above the average size, received from Mr. Austin Fernando, of Veheralanda Watta, Kurunegala. I have not Mr. Fernando's letter beside me, otherwise I should quote from it, but it was stated in the letter that the nut was grown on land that had never been manured, and that the nut had been allowed to mature on the tree.

In the case of the sea-side nut, one third part of the husk, cut longitudinally, was reduced to ashes. If the husk be regarded as built up of three carpels then one-third part corresponds to a complete carpel.

In the case of the inland nut, with a view to minimise the loss of chloride that is liable to take place during incineration, as chlorides of the alkalis begin to volatilise at a red heat, I took only one-sixth part of the husk, corresponding to half a carpel. As- suming the two halves of a carpel or modified leaf cut longitudinally to have the same chemical com- position, a half carpel may be regarded as rep- resentative of the whole husk, while a shorter time is required to reduce the smaller proportion of the husk to ashes, and the possible loss of chloride is therefore proportionally reduced.

The chlorine was the only constituent of the ash that I considered it necessary to determine. This amounted to 26·498 per cent of the ash, which is equivalent to 43·67 per cent of common salt. The following exhibits, in tabular form, a comparison of the results obtained with the sea-side and with the inland coconuts respectively:—

	Seaside Coconut.	Inland Coconut.
Weight of coconut with husk ..	3·482 lb.	4·407 lb.
Weight of nut ..	1·693 lb.	1·914 lb.
Weight of husk..	1·789 lb.	2·493 lb.
Proportion of husk used for analysis ..	one-third	one-sixth
Percentage of crude ash yielded by husk ..	1·938	1·977
Percentage of chlorine in ash of husk ..	24·80	26·498
Percentage of common salt equivalent to chlorine in ash of husk ..	40·87	43·665
Weight of common salt equi- valent to chlorine in one husk ..	·01417 lb.	·02152 lb.
Ditto in 1,000 husks same as those analysed ..	14·17 lb.	21·52 lb.

It will be observed that the larger coconut, although grown on an inland estate, yielded the larger pro- portion of chlorine: and even supposing the incine- ration of the husk of the inland-grown nut to have been conducted with somewhat less loss of chlorides the legitimate inference from these two analyses is that a sufficient supply of common salt must exist in the soil or be supplied to the soil, for the suc- cessful cultivation of the coconut tree.

M. COCHRAN.

THE "AGRICULTURAL GAZETTE" of New South Wales, Vol. VIII, Part 11. Edited by W. H. Clarke. Contents for November, 1897:—Further Notes on the Milling Qualities of the Differ- ent Varieties of Wheat, F. B. Guthrie and E. H. Gurney; Fruit-drying, W. J. Allen; The Culture of Tobacco, A. M. Howell; Summer Pruning of the Vine, M. Blunno; Pruning Ornamental Trees, H. V. Jackson; Profitable Poultry-breeding for the Local and English Markets (Conclusion), Geo. Bradshaw; the Curing of Meats, Reprint; Influence of Bees on Crops, Albert Gale; Bee Calendar for December, Albert Gale; Orchard Notes for December, Geo. Waters; Practical Vegetable and Flower Growing for December, W. S. Campbell; General Notes; Replies to Correspondents; Agricultural Societies' Shows; Label for Specimens.

MINOR PRODUCTS:—DRUG REPORT.

(From the Chemist and Druggist.)

London, Dec. 9.

COCA-LEAVES.—Privately the market is very firm 8d per lb. for fair green sb Truxillo leaves. Of 54 bales Truxillo offered at auction, 6 sold 8d per lb. for fair greenish, and 5d per lb. for ordinary damaged. Nine cases of good Huacoco character leaves from Ceylon sold rather cheaply at 6d per lb.

CROTON SEEDS rem in neglected. At auction ten bags of ordinary part small and dull from Shanghai sold very cheaply at 13s per cwt. Another lot of two bags, rather dark mixed Ceylon, was bought in at 4s per cwt. nominally.

KOLA.—Four small consignments, totalling 27 packages, of West Indian kola were offered at sale today, and a portion sold at 8d for sound, and from 3d to 4d per lb. for damaged quality. Another lot of nice washed West Indian kolas is held for 7d to 7½d per lb., and fair natural at 6d per lb.

OILS (Essential).—Sandalwood oil firmer on account of the advance in the price of wood in India. A fair quan- tity of eucalyptus oil was offered at auction today. At auction there was a rather large supply of Cinnamon oil. One case of this oil was bought in nominally at 4s per oz.; others are limited at from 1s 7d down to 1s per oz. Two cases of very poor rank quality were knocked down at 5d per oz. There is plenty more of this same lot on hand. Lemongrass is extremely firm, and nothing can be had on the spot below 8d per oz., but it seems doubtful whether more than 6d per oz. has yet been paid. There is practically nothing offering to arrive. At auction 10 cases, "land carriage," were bought in. Another lot of 25 cases imported via Hamburg is limited at 8d per oz. At auction it was bought in nominally at 1s per oz. One case distilled W.L. Oil of limes sold at 3s 3d per lb. which sh ws no alteration compared with the last sale at auction. For three cases Nutmeg oil offered 'without reserve,' and sold at lower prices, viz. 1½d to 2d per oz. For Citronella oil, November shipment 1s 1d per lb. c.i.f. terms, in drums, has been paid, and on the spot, nearest quotation is 1s 3d per lb. for drums, and 1s 4d per lb. for tins.

DEAFNESS. An essay describing a really genuine Cure for Deafness. Ringing in Ears, &c., no matter how severe or long standing, will be sent post free.—Artificial Ear- drums and similar appliances entirely superseded. Address THOMAS KEMPE, VICTORIA CHAM- BERS, 19, SOUTHAMPTON BUILDINGS, HOLBORN, LONDON.

COLOMBO PRICE CURRENT.

Furnished by the Chamber of Commerce.)

Colombo, Jan. 4th, 1898.

EXCHANGE ON LONDON: CLOSING RATES. *Bank Selling Rates*:—On demand 1/3³/₄ to 27-32; 4 months' sight 1/3 25-32 to 7-8th; 6 months' sight 1/3 13-13 to 27-32

Bank Buying Rates:—Credits 3 months' sight 1/4 1-32 to 3-32; 6 months' sight 1/4¹/₂ to 5-32; Docts 3 months sight 1/4 1-16 to ¹/₂; 6 months sight 1/4 5-32 to 3-16.

COFFEE.—Plantation Estate Parchment on the spot per bushel R14.75. Plantation Estate Coffee, f.o.b. on the spot per cwt. R80.00. Liberian parchment on the spot per bus. R4.75. Native Coffee f.o.b per cwt. none.

TEA.—Average Prices ruling during the week Broken Pekoe, per lb. 00c. Pekoe per lb. 00c. Pekoe Son-chong per lb. 29c. Broken mixed and 1st Dust, per lb. 00c. Averages of Week's sale. No sales.

“PIONEERS OF THE PLANTING ENTERPRISE IN CEYLON.”

(Second Series.)

SIR JOHN J. GRINLINTON, KT.,

SOLDIER, ENGINEER, SURVEYOR, MERCHANT, COMPANY DIRECTOR, M.L.C.
AND M.M.C. &c., IN CEYLON:—1857 to 1898.

BEFORE the present issue of the *Tropical Agriculturist* is in the hands of the majority of its readers Sir John Grinlinton will have retired from Ceylon where he has been resident for 40 years, and he will carry with him hearty good wishes from all sections of our mixed community for a lengthy period of enjoyment of his well-earned *otium cum dignitate*. He has long taken a keen interest in the affairs of the Colony, and for many years an active part in its public life, rendering good service as a Municipal and Legislative Councillor, Administrator of Companies, and a member of various bodies which have for their object the promotion of the material and moral welfare of his fellow-citizens. He has had a very honourable as well as successful career, and of that career we now propose in this notice to give an outline.

Erect in figure, lithe in limb, and delightfully fresh in complexion, one can hardly think that Sir John has attained his sixty-ninth year, but such is the case. Time has certainly whitened his locks, but his silvery hair and beard only serve to enhance his erect presence and alert bearing. He carries his years extremely well indeed, and we can point to him as a proof of the argument we have frequently advanced that long residence in a tropical climate,

such as that of Ceylon at all events, is by no means inimical to good health or longevity. A son of the late Mr. Thomas Grinlinton of Portarlinton, he was educated in Liverpool at Mount St. Institute, a well-known educational establishment, more especially for boys intended for engineering and mercantile pursuits. It was also at this school that Dr. Archer, late Brigade Surgeon in Ceylon was educated, but the Doctor had just entered when Sir John was about to leave to commence the business of life. Young Grinlinton's natural aptitude for engineering was well developed here, and at an early age he entered the Ordnance Survey Office at Liverpool, where his abilities gained for him the distinction of being selected to assist Major Tucker of the Royal Engineers and the Naval Officer in charge of the survey of the mouth of the Mersey in fixing the Channel and the treacherous sand banks in that locality. The excellent work which he did there attracted notice and led, before he was 17 years of age, to his entering the Royal Engineer Service with a view to special employment at the Ordnance Map Office, Southampton, where in a short time he was placed at important duties under Executive Officer (Colonel Yolland, R. E., and afterwards under the Director General Colonel Hall and the present General Gosset, who was as Capt. Gosset, Surveyor-General of Ceylon). Of General Gosset Sir John always speaks in the highest terms and looking

back on his youthful career refers to the great scientific establishment at Southampton as the school of his life, having there had many unusual opportunities, of which he did not fail to take advantage, of making himself acquainted with many branches of practical science. When at the Map Office he had the honour, during the absence of the Executive Officer, of conducting the late Lord Palmerston round that large establishment and of explaining the work in the various departments—a circumstance which his lordship did not forget when an opportunity occurred of doing a good turn for “his young friend” as he called him. In 1848 the great Railway mania occurred, but although Mr. Grilinton had tempting offers to leave the establishment for good, he was wise enough not to relinquish his fixed post, as many did and repented afterwards. Altogether he served seven years on the Ordnance Survey of England. When a change was made in the Directorship he lost his patrons Colonel Hall and Capt. Gosset. This caused him to think of a new line of life, and having been strongly recommended for a Commission he was gazetted Ensign in the 65th regiment of foot then serving in New Zealand. He, however, did not join his regiment there, but continued for some time further on the Ordnance Survey discharging the same important duties. During the period he was stationed at Southampton he took a keen interest in the Polytechnic Institute, and as a member of Committee had an active part in its management. On handing over his responsible charge in the Ordnance Survey Department he joined the dépôt of his regiment in Jersey in 1854 and became Adjutant. Like most soldiers he desired to see active service, and preferring the rigours of campaigning to a military life in New Zealand he, when the Crimean War broke out, was successful, through the influence he had, in obtaining a transfer to the 4th King's Own. He joined that regiment as Lieutenant in the Crimea in 1855, and was at once placed in General Orders on the recommendation of General Sir Harry Jones (who commanded the Royal Engineers at the Siege) as Assistant Engineer, serving as such through the memorable siege of Sevastopol. It was there he met Capt. Wolsley, afterwards Sir Garnet and now Lord Wolsley, Field Marshal, Commander-in-Chief of the British Army, then in the 90th regiment and looked upon as a first-rate officer, as also the lamented Charles Gordon (R.E.) who was killed at Khartoum. Lieut. Grilinton was also engaged in making a military survey of the Allied positions, and on the fall of Sevastopol on 8th September, 1855, he was mentioned in despatches, recommended for promotion, and received the Crimean medal with clasp, the Turkish medal and the order of Medjidie.

After the peace (in 1856 and '7) he served with his regiment at Aldershot, in Dublin, and in Mauritius; and in 1857 he had the choice of two posts, but he preferred joining his former commanding officer, the present General Gosset, who was then Surveyor-General in Ceylon and who obtained for him a nomination to the Survey Department in this Colony on a commencing salary of £550 a year and allowances in September 1857. He carried with him the goodwill of all the officers of his corps and was presented by (then) Capt. Gosset on his own and their behalf with a very handsomely worded letter and a weighty purse which was most acceptable to a young fellow starting in a new life as a Subaltern in the line on half the pay he had at the Ordnance Map Office.

Sir John's career during his residence in Ceylon extending over a period of 40 years

is pretty well-known to old colonists; but in this sketch it is only right that we should enumerate a number of the prominent matters with which he has been personally identified. He laid out the Rifle Range at Mount Lavinia and was afterwards sent to Negombo and placed in charge of the Surveys in the “Alootoor” and other Korales with a considerable force of Ceylonese who were instructed by him in the duties of field Surveyors. Thus was begun the first effort at a Cadastral Survey in Ceylon and it is interesting to think that the work started by Sir John, may in all probability be completed by his worthy son Mr. F. H. Grilinton who now occupies the important position of Surveyor-General of the island. When the Colombo and Kandy railway works were begun he was placed in charge of the necessary surveys at Marandahn and along the line within the Municipality of all properties to be taken up for railway purposes. About this time the Batticaloa irrigation works had been attracting a good deal of attention and early in 1859 Mr. Grilinton was despatched to that district with a large staff of European and Ceylonese surveyors to survey and make plans of all the lands fit for irrigation and subsequently all paddy lands for tithe commutation and it was when he was engaged in this responsible work that he had a difference of opinion with the then Assistant Government Agent, the late Mr. Woodford Birch (murdered at Perak) on a subject which seriously affected the natives who had purchased land which the works designed up to that time had been unable to irrigate. This difference however, was happily made up, as we have heard Mr. Grilinton say, before Mr. Birch left on promotion for the Straits Settlements. While resident in the Batticaloa District he was obliged to lead a rough nomadic life shifting his talipot camp every few days and travelling through uninhabited jungles known only to Veddahs and some native hunters and which very few Europeans ever visited. This was all in the course of his work in superintending the trigonometrical survey of the province; but a good deal of sport came in his way and he had what may be described as the “cream of shooting.” It was during his wandering in these lonely localities that he made the acquaintance of many of the Veddahs (some of whom acted as his guides) through the assistance of a Vedarala (native doctor) who stated that his mother was a Veddah. He found them at first to be extremely shy and they frequently ran away; but afterwards they became more intimate and he speaks of them as being on the whole a docile simple-minded people. After nearly four years spent in the Eastern Province Mr. Grilinton was transferred to the Southern Province, where he interested himself in a design for an improvement of the Galle Harbour and was granted a free passage home and back by the P. & O. Co., in order that he might further the designs. In 1865 he was brought to the Colombo Office and was Executive officer until the close of 1871 in which year he went home on leave of absence to study the narrow-gauge light railways system for the purpose of seeing whether they could be introduced to Ceylon, and had it not been for a difference with the Governor (Sir William Gregory) it is very likely that much good would have resulted from the work he did then in England and Scotland, a former commanding officer—Colonel Yolland—who was then Inspector of Railways (and who had known Mr. Grilinton well on the Ordnance Survey) having furnished him with introductions to the engineers of every light line known to the Inspector General. In 1866 he was appointed

one of five official members to the Municipal Council and was chosen as Chairman of the Public Works Committee, and during his six years of office he designed the first Public Latrines and received the thanks of the Council. He was asked to report on a Water Supply for the City, which he did at a considerable cost to himself. For this also he received the thanks of the Council; and to him the public are indebted for having led the way in introducing Gas into Colombo. In 1871 he along with others, (Capt. Fyers, R.E., Captain Donnan, and Capt. Graham) sent in designs to Government for a Breakwater to protect the Harbour of Colombo on which the Admiralty Engineer, Mr. Townsend, passed encomiums. This Engineer, however, considered (among other things) that a northern arm which formed a part of the design and a graving dock with tramway round the shores of the Harbour were more than could be undertaken. Time, however, has shown that all have been found necessary. In the year 1868 during the total Eclipse of the Sun, Mr. Grinlinton took special observations from the top of Trinity Church for which he was thanked by Astronomical authorities in England and America.

In 1872 Mr. Grinlinton resigned the public service and was immediately appointed Managing Director of the Gas Works. He likewise adopted mercantile pursuits and established Manure Works outside Municipal limits where he converted the offal of the Municipality and the scavenging of the town into fertilising material, there being added to it sulphate of ammonia with some thousands of tons of fish from the coast of India with ammoniacal liquor and gas-lime from the Gas-works. This proved a most successful undertaking as also did certain speculations in the purchase of large cargoes of teak from Burmah. In both of these ventures he was cordially aided financially by his esteemed friend, Mr. White, then the senior partner of Messrs J. M. Robertson & Co. On the visit of H.R.H. the Prince of Wales in 1875, Mr. Grinlinton was chosen as one of the Honorary Secretaries for the reception and the indefatigable efforts then made to make the illumination of the City and the large ball-room built at the Galle Face Club a success, caused the Governor to specially present Mr. Grinlinton to H. R. H. and to send him a letter of thanks for his special services. In 1876 the Wharf and Warehouse Co. was in very low water, and the post of Manager was offered to Mr. Grinlinton and he continued in the Company as Manager and Managing Director for a period of 20 years leaving it in a flourishing condition. In 1882 he accepted in addition to his other duties the Managing Directorship of the Colombo Hotels Co., Ltd., which at the time was in a very low state, its R100 shares selling at R15 and R20 and in 1888 he became also Chairman which post he now vacates, the present quotation of shares being R335. In the Jubilee year of Her Majesty the Queen, he was a member of the Committee which undertook the preliminary and active proceedings in raising funds and carrying out the object sought to be obtained and has ever since taken an interest in the Royal Victoria Home for Incurables, then established, of which he is a Life Governor and a member of Committee. In 1887 on the formation of the Irrigation Board he was appointed an Unofficial Member and his unremitting labours in connection with that Board are well-known and have been recognized by successive Governors. In 1888 he was appointed to the European seat in the Legislative Council and the general public know the keen interest taken in every question of importance that has come before that assembly, the latest instances being

his propositions in connection with sanitary management on the railway and the fares on the sea-side line, and in strongly advocating Railway extension on a narrow gauge (the metre he prefers) and on Irrigation he is ever "at home." A fluent and forcible speaker Sir John makes his points well and has always been listened to with close attention by his fellow members. He seldom if ever speaks except on a subject with which he is familiar or has carefully studied and it is generally admitted that he puts his case in a very strong light. In 1891 when preparations were being made for the Chicago Exhibition he was selected by the Planters' Association, Chamber of Commerce and the public in general as Special Commissioner and was so gazetted by Government, and during some months in 1892 and whole of 1893 he was at Chicago.

In 1891 Mr. Grinlinton succeeded (after more than a year's pressing the subject forward unofficially) in attracting the attention of Government to Uplands as the best site for a Graving Dock which could be made suitable for the largest ships in Her Majesty's Navy and the Mercantile Marine. A Commission was appointed by the Governor, Sir Arthur Havelock, to report on the subject, and the opinion of the Commission being unanimous, the site is now about to be converted into one of the finest Graving Docks in the world.

On the 25th March, 1894, soon after Mr. Grinlinton's return from America, he received the great blow of his life in the death of his wife who had been in delicate health for some years. This amiable lady was a daughter of the late Mr. Booth of Southampton, and her hospitality and benevolence are well known to many of the present residents of the Island, more especially to those who visited Nuwara Eliya. She had followed the fortunes of her husband to Mauritius and Ceylon, and was often with him in his journeys through remote parts of the Island where she made good use of her opportunities in writing interesting descriptions of her travels which have been preserved, and are to see the light at some future day.

Her belief in her husband was unbounded, and we do not wonder at the blank he now feels leaving this country alone and practically for good to take up his residence at Middle Wallop in Hampshire.

We attach an official record of Sir John Grinlinton's service:—

GRINLINTON, Sir JOHN J., M.L.C., A.I.C.E.,
F.R.G.S., F.S.A. &c.,
son of the late Thomas Grinlinton, of Portarlington; was seven years on the Ordnance Survey of England, gazetted Ensign in the 65th Regiment, appointed Depot Adjutant, served the Crimean Campaign of 1855-56 as Lieutenant 4th King's Own Regiment, and Assistant Engineer during the siege of Sebastopol; was also engaged making a Military Survey of the allied positions, was mentioned in Despatches on the fall of Sebastopol, 8th September, 1855; Crimean Medal with clasp, 5th class of the order of Medjidie, and the Turkish Medal; Assistant Surveyor-General, Ceylon, 1857; retired from the Army by the sale of his commission 1858; appointed an Official Councillor of the Municipality of Colombo at its formation in 1866, and served for six years; resigned the Public Service 1872, and subsequently followed Mercantile pursuits; Member of the Central Irrigation Board 1887 to 1897; Councillor of the Municipality of Colombo (for a second time) 1887 to 1897; Member of the Legislative Council of Ceylon (to represent the European Community) 1888; Special Commissioner for Ceylon at the World's Columbian Exposition, Chicago, 1893; *m. Emily*, daughter of the late Mr. Isaac Booth, who died 1894; *cr. K. B.* 1894.

Colombo, Ceylon, and Rose Hill, Middle Wallop, Hants. Clubs:—Royal Societies and the Junior Constitutional.

He leaves two sons here—the elder Mr. Frederick H. Grinlinton being Surveyor-General of the Island, and the younger, Mr. Edward Gordon Grinlinton who has been a successful Tea Planter and who resides at Yalta, Nuwara Eliya. His only surviving daughter, Mrs. Coventry, proceeded to England last December.

Finis coronat opus!—The finishing touch to Sir John Grinlinton's career in Ceylon was put in the most cordial and successful and (in some respects) unique banquet accorded to him on the night of the 4th inst. by representatives of all sections and classes of the community, and which was honoured with the presence of the Queen's representative. Surely no old colonist or hardworked public man could desire a more congenial or fitting "send-off." He has not lagged "superfluous on the stage," but leaves at a time when the whole community must feel that his absence creates a blank, and when "troops of friends" regret the decision which makes his departure necessary. Sir John Grinlinton, though close on the ordinary limit of human life, is still hearty and vigorous, and his age is as "a lusty winter, frosty but kindly." No one can grudge a time of rest and retirement in his Hampshire home; but we may be certain of learning that he has found means of being useful in his new surroundings, while we may all look forward to a visit some years hence both to India and Ceylon. And so we take farewell of the worthy Knight—we have personally followed his career for over 36 years, always with interest, sometimes with criticism in words of praise or censure as the case might be, but more generally with feelings of admiration for the pluck, enterprise and indomitable industry which have marked his career. If we wished to sum up Sir John Grinlinton's character in a couplet we could not find one more fitting than that of the poet Wordsworth:—

'A man he seems of cheerful yesterdays
And confident tomorrows.'

RUBBER CULTURE.

A POSSIBLE AUSTRALIAN INDUSTRY.

An age of stone, of bronze, of iron, and also, say the scoffers, one of brass, has the world passed through in turn; is it too much to claim that we are now in the rubber era, considering to-day the multitudinous articles in common use, the manufacture of which is impossible minus the indispensable inspissated juice known as caoutchouc. Indian rubber comes from many countries, but the principal supplies have been secured heretofore from tropical South America, West and East Africa, Burmah, Assam, &c. Over extensive areas of these countries the different species of rubber trees are to be found, & though nature in the past has been so generous to man's wants in the present pneumatic tyres, &c., so great is the demand and so wasteful the usual process of rubber collections—left as it mostly is to either ignorant, savage, or semi-civilised savages, taking little heed for the to-morrow of manufacturers—that specialists are casting around for fresh fields of exploitation; their prognostications

being that nothing is more sure than a half response, or less, to the future cry for raw material. And this is owing to the exhaustion of the known forests, thanks to ruthless destruction of trees and lack of forethought in the matter of replanting.

Not so many years ago the Amazon valley with its *Hevea Braziliensis* yielded more than enough rubber for the world's use—and the real rubber trade may be said to have commenced less than thirty years ago—to-day this supply has been supplemented from the *Hancornias* of Pernambuco, the *Manihots* of Cara, the *Landolphias* and *Kick-sias* of West and East Africa, not to speak of the *Ficus Elastica* of the East and the celebrated *Castilloa* of Central America. And yet the prices are slowly rising! Needless to say the manufacturing outlook is viewed with some uneasiness. Accordingly in other climes certain far-seeing people have started plantations, more particularly of the *Castilloa*, the *Hevea*, and the *Manihot*, whilst the Germans, with their usual thoroughness, in their West African possessions are making systematic attempts to propagate the *Landolphias*. And that the harvest to be reaped will be satisfactory is assured. The profits, based on present prices, at the expiration of the eighth year can be reckoned on at 300 per cent.

The parts of the world above mentioned are tropical, with a minimum average temperature of 66 F., combined with a heavy rainfall (though the *Manihots* and *Hancornias* do not require too much moisture), and it has always been laid down as a botanical postulate that Rubber and Rain, Miasma and Monkeys, are an indivisible quartette. But the knowledge of the earth's good things increases always. For example in 1893 the output of caoutchouc from Lagos, West Africa, was practically nil. Comes along one Kicks, who discovers a hitherto unknown tree. Its product is sent to Kew Gardens, London, for report, which being satisfactory, by 1895 nearly 4,000,000 lb. of rubber had been exported from that British Possession. But this by way of illustration only of what fresh discovery has done for the rubber market, for Lagos is an equatorial province. What is of far greater import to us is whether there is any possibility of the cultivation of any known tree in New South Wales. And considering what immense advantages would accrue to the farmer and planter by so doing no research for such a valuable kind of tree could be too comprehensive and no experiments too exhaustive, for the successful introduction of rubber-growing into New South Wales would mean an additional £1,000,000 to our annual export schedule. Surely an attempt to acquire such an increase is worth more than academic scepticism.

Twenty years ago that distinguished savant, the late Baron Von Mueller, stated emphatically that the *Ficus elastica* (E. Indies), being so closely allied to the *Ficus* species known here, would grow in the Gippsland valleys and gullies. Nothing so far has been done towards founding such an industry. However, opinions differ as to the speed of growth of this tree, for though experience elsewhere, in Ceylon, &c., quotes an average of eight years ere maturity is attained, it is at least likely in a fair cooler climate that the wait would have to be at least 25 per cent. longer. The deceased Baron spoke, too, of the well-known Port Jackson fig (*F. Rubiginosa*) which on analysis gives—Resinous sycoretin, 73; Acetate sycoceryl, 14; Caoutchouc, 13—100.

And the Apocynaceous "bitter bark," akin to the West African variety, is also reported to yield a fair percentage of commercial rubber when leaf and stalk crushing are resorted to. Beyond these *Lactaria Calocarpa* and *Lactaria Moorci* have been suggested by some writers as possible caoutchouc givers.

So much for the known Australian trees themselves. Remains now to be seen whether there are any quick growing varieties obtainable from other countries which are suitable to the climate, say, of the Tweed, Richmond, and Clarence rivers. And, it appears, while the *Castilloa* might possibly meet the case, it is more than probable that the *Sapium Biglandulosum* would do so.

There is considerable difference of opinion as to the flourishable habitat of the Castilloa so far as New South Wales is concerned. Ordinarily speaking it is found best suited to tropical localities with a heavy rainfall; but it has been claimed that, owing to its adaptiveness, a sub-tropical climate would supply the necessary environment. Moreover it is at least suggestive to find the Ipomea Borna Nox, the juice of which is used to coagulate the caoutchouc milk of the Castilloa in Mexico, should grow luxuriantly in many part of New South Wales. So far, it is believed, no castilloas have ever been introduced into New South Wales. When full-grown it is a magnificent forest tree; but it must not be confounded with the Castilloa Markhamii, which belongs to the Perebea class. At maturity this tree's trunk often measures 10ft. in circumference, and its height will sometimes top 130 ft. It is easily distinguished by its immense hairy, oblong, and lanceolate leaves, often 18 in. by 7in., which are subtrigose, as also are the branchlets the colour on the latter being buff. It is of small foliage area, taprooted, and requires a scrub surrounding when young. If grown as in a plantation the seeds should be set at a distance of 15ft. apart in uncleared ground. This is most important, a small area of about 1ft. in diameter being left clear around the young plant. So much do these trees desire shade in their youth that tests prove that whereas seedlings planted in uncleared ground develop a 9 in. trunk diameter, and flower and fruit in four years, those planted in well-cleared ground show nothing like similar advancement. In point of fact the young Castilloa needs above all things shade, for its stem's growth and juice supply else will be checked. Once suitably planted they require little or no attention. The rubber obtained at the fourth or fifth year is worth 2s 9d to 3s per lb., and so far as is known the tree with each year gives a large increase, expanding in geometrical progression. As for the collection of the juice and its metamorphosis into a commercial product that is an easy matter. It may be here added that recent discoveries show that a fair supply can be obtained from a crushing of the leaves. Whether this deciduous tree could be grown on the sugar lands of New South Wales has yet to be proved.

The other tree, the Sapium aforesaid, which it is likely could be advantageously introduced here, is one of the Euphorbiaceæ. For years past rubber has been exported from the Port of Cartagena, and under the name of that Colombian city it was supposed to be a species of castilloa. This idea, however, is exploded, and the sapium mentioned now gets its due credit, with the acquiescent approval of the botanical authorities at Kew Gardens (vide "Kew Bulletin"). To Mr. R. B. White is due the honour of the initiatory indications on which subsequently Mr. Rob. Thompson, formerly in charge of the cinchona plantations, Jamaica, went so successfully to work. Mr. Thompson, who now resides at Chappell, Sante Fe de Bogota, Colombia, has established since 1891 a plantation of 70,000 sapium trees, and in his report to Kew he states that this tree—trade name of it, "Colombia virgin"—has this peculiarity; "Unlike all other known sources of this substance it grows at a high elevation, and therefore, in a comparatively cool climate." There can be little doubt that the tree is one of the multiform varieties of the Sapium biglandulosum (Muell. Arg.), one of the Euphorbiaceæ, to which the Para hevea and the Ceara manihot belong. The variegations which this widely-spread species present are as extreme as are to be met with in the vegetable kingdom. . . . Under cultivation this tree thrives admirably, growing with great rapidity at the rate of 5ft. per year. Crops are obtainable in five to six years, at five years, the yield begin 1lb. of rubber per tree, which is worth about 2s 6d per lb., and when matured the tree, planted at the rate of 150 to the acre, attains a diameter of from 6ft. to 7ft. This, bear in mind, has received the cachet of Kew.

Mr. Thompson's plantation, lying at an elevation of between 6,000ft. and 7,000ft. above the sea level, is on land quite useless for other purposes, and so much

success has attended his efforts that at Monteiro, Rio Sinn, Mons. M. P. Durand has put in no less than 100,000 cuttings and seedlings, which are now flourishing. Mr. Thompson, so the "Kew Bulletin" reports, has offered the Indian Government to deliver at the Nilgiris a large supply of Sapium plants and seeds insured to germinate for £1,000. Inquiries as to this tree are now being made by the higher authorities in Sydney, and should the replies be satisfactory no doubt an attempt will be made to acclimatise this tree.

Before concluding this article, it is as well may be, to disabuse the public mind of the belief that very cheap labour is required to make rubber-getting by tree-tapping a success. In the first place, little or no labour is needed until the trees have sufficiently grown. In the second place, from personal experience, and quoting from an exhaustive article on this industry as carried on by the half-civilised half-bloods of the Amazon Valley, those mestizos can and do earn £1 per day during the season of five months.—*Sydney Mail*.

CATALOGUE OF COCCIDÆ COLLECTED IN CEYLON.

BY MR. E. E. GREEN.

[The following list of Coccidæ, which contains many undescribed species, is to be regarded as preliminary to a more exhaustive paper with figures of all the new species, now in course of preparation by the same author.—*Ed.*]

1. *Chionaspis brasiliensis*, Sign.—On cultivated ferns, *Strobilanthes* sp., and *Acacia melanoxylon*, occurring, when present, in enormous numbers, the males usually predominating. A remarkable exception being in the case of specimens found on the *Acacia* which were all females.

Locality Punduloya.

2. *C. biclaris*, Comst.—Very common on stems of Cinchona and Tea, sometimes in such numbers as to considerably injure the plants. Found also occasionally on stems of *Grevillea* and Coffee; never on leaves, though the American type is described from examples found on leaves of fig. Male unknown. The female shield very inconspicuous, from the fact that it is always covered with the superficial fibres and loose material of the bark upon which it rests.

Locality Punduloya.

3. *C. aspidistæ*, Sign., var. *mussendæ*, n. var.—Found on stems and twigs of *Mussenda frondosa*. Differs from type chiefly in the character of the female shield, which is opaque, greyish white, and covered with the hairs and fibres of the bark instead of being of a "clear transparent yellow" as in Signoret's type. The male puparia are crowded together in large groups, each individual attached by the anterior extremity only, the rest of the body elevated.

Locality Punduloya.

4. *C. eugeniae*, Mask., var. *varicosa*, n. var.—Found on under surface of leaves of *Gelonium lanceolatum*. Differs from type chiefly in character of female shield, which is proportionately broader and marked with ramifying raised creases resembling veins.

Locality Punduloya.

5. *C. eugeniae*, Mask., var. *litzeæ*, n. var.—Found on under surface of leaves of *Litsea zeylanica*. Differs from type in the female shield being very thin and semi-transparent. Male with 3 knobbed digitules on feet.

Locality Punduloya.

6. *C. vitis*, n. sp.—Found on under surface of leaves of *Vitis*, producing discoloration of the leaf, the punctured parts turning pale yellow. Very occasionally found on upper surface of leaves of *E. agnus*. Female shield thin, colourless and semi-transparent. Pygidial lobes small but prominent. Female insect pale yellow before gestation; afterwards reddish. Male with 4 knobbed digitules on feet.

Locality Punduloya.

7. *C. graniniæ*, n. sp.—On lemon-grass (*Andropogon*). Punctured area of leaf turning dark purple. Female

shield snowy white; insect reddish orange. Pellicles of male puparium dark brown. Adult male with 3 knobbed digitules on feet.

Locality Punduloya.

8. *C. minuta*, n. sp.—On *Tetranthera*. A very small species, appearing to the naked eye like minute yellowish specks on under surface of the leaf. Female shield colourless and transparent. Male puparium also very thin and transparent. Adult female insect very pale yellow. Male with 3 knobbed digitules on feet.

Locality Punduloya.

9. *C. acuminata*, n. sp.—Found on both surfaces of leaves of *Arctisia* and several unidentified plants. Female shield very long and narrow with a median ridge, yellowish brown. Insect very pale yellow, tinged with bright orange in order individuals. Pygidia lobes very small. Male puparium strongly carinate, the furrows coloured reddish, giving a general pink tinge to the mass. Feet with 3 knobbed digitules. Terminal point of antenna with 3 knobbed hairs.

Locality Punduloya.

10. *C. elæagni*, n. sp.—On *Elæagnus latifolia* under surface of leaves. Female shield thin, whitish, but closely covered with the stellate hairs of the leaf. Insect bright yellow. Pygidium reddish. Pygidial lobes large and prominent. Male with 3 knobbed digitules on feet.

Locality Punduloya.

11. *C. exercitata*, n. sp.—On both surfaces of leaves of Tea, *Psycaotria* and other plants, in colonies consisting usually of one, or a very few females and a large number of males; the white carinated male puparia being disposed very regularly in parallel lines. Female shield long and narrow, reddish brown. Insect dull purplish red; pygidium with single median lobe. Male with 2 knobbed digitules on feet.

Locality Punduloya.

12. *Aspidiotus nerii*, Bouché.—Common on Tea, *Loranthus*, *Dalbergia*, Palms, etc.

Localities Punduloya, Kandy, Colombo.

13. *A. aurantii*, mask.—On Agave (American aloe) and *Citrus pomela*.

Locality Punduloya.

14. *A. osbeckia*, n. sp.—On stems of *Osbeckia*, not common. Allied to *nerii*, but differs in the opaque brownish shield, and the marginal hairs of the insect. Male with black apocema. Feet with 4 knobbed digitules. Terminal joint of antenna with 3 knobbed hairs.

Locality Punduloya.

15. *A. oculatus*, n. sp.—In minute galls on leaves of *Grewia orientalis*. Female pale yellow: no grouped spinnerets. Male with 4 digitules on feet, and 3 knobbed hairs on terminal joint of antenna.

Locality Punduloya.

16. *A. trilobitiformis*, n. sp.—On leaves of unidentified tree. Female shield broad and flat, opaque, reddish brown. Insect very regularly and symmetrically formed; segments strongly marked: a deep transverse groove behind the cephalic segments. Pygidium with well-marked reticulated path on upper surface.

Locality Punduloya.

17. *Diaspis lanata*, Morg. and Ckll.—Very common on stems of geranium. *Callicarpa lanata* and *Tylophora asthmatica*. Very destructive to cultivated geranium, the stems often being completely covered with the white male puparia.

Locality Punduloya.

18. *D. cuculata*, n. sp.—Common on young tea plants and on the twigs of older bushes: also on *Cinchona* and *Osbeckia*. Female shield yellowish: pellicles usually dark, with a small whitish central boss surrounded by several concentric raised circles. Insect yellow. Male unknown.

Locality Punduloya.

19. *Mytilaspis citricola*, Packard.—On orange, and leaves of *Cocculus indicus*.

Localities Punduloya, Kandy.

20. *M. elongata*, n. sp.—On leaves of *Arundinaria*. Female shield very long and narrow, snowy white. Insect also very long; almost linear; pale yellow to orange. Male with 4 knobbed digitules on feet, and 6 knobbed hairs on terminal joint of antenna.

Locality Punduloya.

21. *M. pallida*, n. sp.—On leaves of unidentified shrubs. Allied to *M. citricola*. Female shield proportionately longer, smoother and more regular, very pale yellowish or brownish. Insect creamy white: pygidium pale reddish. Male pale lilac: foot with 3 knobbed digitules: terminal joint of antenna with 3 knobbed hairs.

Locality Punduloya.

22. *Aonidia corniger*, n. sp.—On upper surface of leaves of *Psychotria* and *Litsea*. A very remarkable form, the first pellicle bearing a series of 16 long, glassy, colourless horn-shaped processes. Adult female pale lilac: completely enclosed within second pellicle: pygidiums without spinnerets: margin produced into tooth-like processes.

Locality Punduloya.

23. *Fiorinia saposnæ*, n. sp.—On under surface of leaves of *Saprosma*. Female shield almost completely occupied by the second pellicle, which is pale orange coloured. Male puparia concealed beneath a mass of loose white filaments. Female insect pale yellow: minute jointed tubercles on margins of abdominal segments. Locality Punduloya.

24. *F. secreta*, n. sp.—In small galls on leaves of *Grewia orientalis*. Female insect yellow: pygidium long and pointed, with a prominent double median lobe: no grouped spinnerets.

Locality Punduloya.

25. *F. serobicularum*, n. sp.—In glandular pits at base of veins on leaves of *Garrucra karigii*. Female shield very narrow in front, widened behind; pale yellowish with reddish median area. Insect pale yellow: pygidium with deep median cleft.

Locality Punduloya.

26. *F. Palmæ*, n. sp.—On fronds of Coconut palm. Differs from *F. saposnæ* in smaller size, and in possession of a long stout spinelike process on rudimentary antennæ.

Locality Punduloya.

27. *Planchonia bambusæ*, Boised.—On stems of Giant Bamboo. Male unknown.

Locality Punduloya.

28. *P. miliaria*, Boisd., var. *longa*, n. var.—On *Arundinaria*. Differs from type in proportionately greater size and length. Male yellow. Terminal joint of antenna with 3 knobbed hairs.

Locality Punduloya.

29. *P. delicata*, n. sp.—On leaves of *Arundinaria*. Much less convex than *P. bambusæ*: sometimes almost flat. Male reddish; antennæ with 6 very long whip-like hairs, and 3 knobbed hairs on terminal joint.

Locality Punduloya.

30. *P. solenophoroides*, n. sp.—on leaves of *Arundinaria*, a minute species. Hinder part of female test narrowed and elevated. Insect bright yellow. Male pale yellow; foot with 3 digitules: antenna with 3 knobbed hairs at apex.

Locality Punduloya.

31. *Walkeriana floriger*, Walk.—On stem of *Litsea zeylanica*.

Locality Punduloya.

32. *W. compacta*, n. sp.—On stem of unidentified tree. Without the silky filaments and tufts of *W. floriger*. Short, stout, compact, conical white processes on dorsum.

Locality Kelani valley.

33. *W. euphorbiæ*, n. sp.—On branches of *Euphorbia antiquorum*. Very convex behind; narrowed and depressed in front. Short curved conical processes in concentric series.

Locality Hambantota.

34. *W. polcii*, n. sp.—On stems and twigs of *Dodonæa viscosa*. Pinkish grey: short, conical, truncate yellowish processes: very convex dorsally: laterally compressed inner side of femur with stout spines.

Locality Chilaw.

35. *W. seneg*, n. sp.—On stems and twigs of *Dodonæa viscosa*. Broader, flatter than *W. Polcii*: processes very long and curling white or brownish.

Locality Chilaw.

36. *Orthezia insignis*, Dougl.—On numerous ornamental shrubs, affecting specially *Acanthaceæ*. A very destructive species. Male slaty-grey with a brush of long silky filaments from extremity of abdomen. This species has been redescribed from Ceylon specimens by Mr. Buckton under the name of *O. naerea*; but I can find no distinguishing points between this and the species from Kew. In fact our specimens are doubtless the direct descendants from the Kew insect, as they first appeared in the plant-houses of the Government Botanical Gardens at Paradeniya.

Locality Kandy.

37. *Monophlebus zeylanicus*, n. sp.—On trunks of *Antidesma bunius*. Female bright orange-red: rather long and narrow. Insects of second stage occupying small cells in the living tissue of the bark.

Locality Punduloya.

38. *Icerya ægyptiaca*, Dougl.—On leaves of variegated Croton.

Locality Chilaw.

39. *I. tangalla*, n. sp.—On leaves of unidentified plant. Differs from *ægyptiaca* in absence of dorsal waxy cushions, and the marginal processes being very short, stout and truncate.

Locality Tangalla.

40. *I. crocea*, n. sp.—On leaves of Citrus, Croton and Cocculus. Body reddish orange: dorsal area covered with bright yellow mealy secretion, with double marginal series of yellow waxy tufts and numerous delicate silky filaments.

Locality Punduloya.

41. *I. pilosa*, n. sp.—On a species of wiry grass growing on seashore. Body dull crimson: dorsal area completely covered with white granular powder and short white filaments: skin with blackish hairs.

Locality Chilaw.

42. *Eriococcus arancariæ*, Mask.—On *Arancaria*, occurring locally in enormous numbers, making infested trees quite unsightly from the sooty fungus that accompanies the insect.

Locality Newera, Eliya.

43. *Coccus cacti*, Anct., var. *ceylonicus*, n. var.—On *Opuntia*. Differs from type in proportions of antennæ in different stages. Male, with a pair of longish knobbed hairs on each of last seven joints of antenna.

Locality Hambantota.

44. *Pseudococcus mangiferae*, n. sp.—On *Mangifera indica*. Female pale yellow, dorsal area covered with white mealy powder, except on a subtriangular median patch: a marginal series of stout white fragile processes. Male very pale yellow.

Locality Punduloya.

45. *Dactylopius adonidum*, Lin.—On nearly every cultivated plant and in every part of Ceylon.

Localities Punduloya, Kandy, Colombo, Chilaw, Hambantota.

46. *D. longifilis*, Comst.—On *Fasminum* and *Adiantum*.

Localities Punduloya, Kandy.

47. *D. talini*, n. sp.—On *Talinum*, *Lilium*, Croton. Female purplish brown, sparsely dusted with white powder: a single pair of longish stout filaments at abdominal extremity: numerous long, very delicate, colourless, glassy filaments.

Localities Colombo, Kandy, Chilaw.

48. *D. scrobicularum*, n. sp.—In glandular pits at base of veins of leaves of *Elæocarpus*. Dark slaty-grey, sparsely covered with whitish powder, abdominal segments only with stout white processes, which protrude from the opening of the cell in which the insect lives.

Locality Punduloya.

49. *Vinsonia stellifer*, Westw.—On leaves of Mango, *Ficus antimesma*, Coconut palm and other shrubs.

Localities Punduloya, Kandy, Colombo.

50. *Ceroplastes floridensis*, Comst.—On Tea, Mango and Citrus.

Locality Punduloya.

51. *C. ceriferus*, Anders.—On stems of *Antigonon* and *Poutzolia*. Specimens from the hills less than half size of those from low country.

Localities Punduloya, Chilaw.

52. *C. actiniformis*, n. sp.—On leaves of Coconut palm. Very convex. Median area of test with radiating purple lines.

Localities Punduloya, Kandy.

53. *Putvinaria psidii*, Mask.—On Guava, Tea, Cinchona and numerous shrubs and plants. Occurring in enormous numbers and doing considerable injury to infested plants.

Locality Punduloya.

54. *P. tessellata*, n. sp.—On leaves of *Ophiorrhiza pectinata*. Female scale with tessellated markings; bright green oviseac, fluted.

Locality Punduloya.

55. *P. tomentosa*, n. sp.—On unidentified tree. Female scale olive-brown; median area rather thickly covered with small balls of tightly curled woolly filaments, oviseac with deep median longitudinal furrow.

Locality Punduloya.

56. *Lecanium coffeæ*, Walk.—Common on leaves and stems of Tea, Coffee, various ferns, and numerous other plants.

Localities Punduloya, Kandy, Colombo, etc.

57. *L. longulum*, Dougl.—On branches and twigs of *Albizia* and *Grevillea*.

Locality Punduloya.

58. *L. viride*, Green.—On Coffee, Cinchona and numerous shrubs and trees. A very injurious species. But though it has killed out the coffee in whole districts, it has fortunately not seriously attacked Tea.

Localities Punduloya, Kandy, Colombo, etc.

59. *L. mangiferae*, Green.—On leaves of cultivated mango trees.

Locality Punduloya.

60. *L. nigrum*, Nietner.—Rather Common on various shrubs and plants, Croton, Asparagus, *Begonia*, *Cobæa*, etc. Though originally described from coffee, it is now very seldom seen upon this plant.

Localities Punduloya, Kandy, Colombo, etc.

61. *L. tessellatum*, Sign.—Rather common on leaves of *Caryota urens*. Found also on Cinnamon and some other shrubs.

Localities Punduloya, Colombo.

62. *L. planum*, n. sp.—On upper surface of leaves of unidentified tree. Bright castaneous to dark chocolate brown. Flat, broad. Subtriangular: pointed in front. Antennæ 6-jointed. Margin with continuous fringe of very delicate overlapping fan-shaped scales. Dermal cells small and circular on median area, oblong and irregular towards margin. Male puparium divided into 18 plates. Adult male without caudal filaments.

Locality Punduloya.

63. *L. planum*, var. *maritimum*, n. var.—Found on both surfaces of leaves of a thorny shrub growing on the sea-shore (within reach of surf). Differs from type in smaller size and absence of dermal cells. Scale protected by a secretion that becomes tough and gelatinous under treatment with potash.

Locality Bentota.

64. *L. geometricum*, n. sp.—On leaves of unidentified shrub. Pale castaneous, or fulvous. Flattish, sub-circular, median dorsal area with concentric series of polygonal depressed spaces. Antennæ 6-jointed. Marginal fringe of overlapping fan-shaped scales. Dermal cells oblong, irregular.

Locality Punduloya.

65. *L. marginatum*, n. sp.—On upper surface of leaves of *Psychotria thwaitesii*. Pale fulvous to castaneous, a sub-marginal zone almost colourless. Oval, pointed in front. Antennæ 6-jointed. Marginal fringe of overlapping semi-circular scales. No dermal cells. Male with long caudal filaments; costal nervure of wing bright carmine.

Locality Punduloya.

66. *L. expansum*, n. sp.—On leaves of *Litsea* and *Dalbergia*. A very large flattish species. Longest diameter nearly $\frac{1}{2}$ inch. Margin with continuous fringe of fan-shaped scales. Antennæ obscurely 6(?)-jointed. Legs wanting.

Locality Punduloya.

67. *L. antidesmae*, n. sp.—A single specimen found on leaf of *Antidesma bunius*. Very flat, but opaque; reddish brown with a thin-greyish powdery film.

Antennæ 8-jointed. Margin with simple stoutish hairs. A distant series of short, fine, white cottony filaments springing from glandular spots near margin.

Locality Punduloaya.

68. *L. caudatum*, n. sp.—Very abundant on leaves of *passiflora*, occasionally on Coffee. Convex oblong, oval; broadest behind. Colour varying with age from bright orange to deep chestnut brown; the paler specimens with a dark brown longitudinal and several transverse bands. Three or four very long white thread-like filaments springing from anal aperture, frequently extending two or three times length of insects. The hairs from ano-genital ring very conspicuous, stout and dark coloured; marginal hairs dilated and toothed. Antennæ 7-jointed.

Locality Punduloaya.

69. *L. acutissimum*, n. sp.—On under surface of leaves of Coconut and other palms. Very narrow; pointed in front and behind of the shape and size of a carroway seed. Reddish brown to black. Antennæ 6-jointed. Single stigmatic spine.

Localities Punduloaya, Kandy, Colombo.

70. *L. piperis*, n. sp.—On leaves of wild pepper, upper surface. Female broadly oval, flattish, with prominent median longitudinal, and two transverse ridges. Pale fulvous to pale reddish brown. Antennæ 8-jointed. Stigmatic spines in deep cleft, four to six. Male puparium divided into 18 waxy plates.

Locality Punduloaya.

71. *L. ophiorrhiza*, n. sp.—On leaves and stems of *Ophiorrhiza pectinata*. Oblong, pointed in front. Pale fulvous with dark reddish, reticulated pattern. Stigmatic spines three, the central one very long and prominent. Antennæ 8-jointed. Male puparium composed of 9 glassy plates, a median longitudinal series of prominent points.

Locality Punduloaya.

72. *L. formicarii*, n. sp.—On stems of Tea and other shrubs, always sheltered by nests of a small brown ant (*Crematogaster*, sp.). Highly convex, almost globular; dull brown.

Locality Punduloaya.

—*Indian Museum Notes.*

YIELD OF BLUE-GUM PLANTATIONS.

From some interesting figures lately supplied us by a correspondent, we gather some valuable information regarding the yield of fuel from gum plantations:—

Years.	Age.	Elevation. Feet.	No. of trees per acre.	Stack per acre.	Annual increase per acre.	Average dimensions of trees.	Annual increase per tree.
1	5	7,235	847	2,966	593	3-5	0-2
2	6	5,954	980	2,151	302	2-2	0-3
3	9	6,694	1,045	5,963	503	5-7	0-6
4	10	7,382	469	6,894	585	14-7	1-4

Equivalent of cubic feet in tons is 45 cubic feet = 1 ton, Govt. ratio.

Taking the question of elevation first, it will be seen that the highest plantations give decidedly the best results, both in actual stock and annual increase per acre. Naturally the youngest plantation (No. 1) leads the way in annual increase per acre, while it is undoubtedly the lower elevation that make No. 2 and 3 so inferior to the others. No. 4, by the way, is the average of two plantations, very similar in age, elevation and other details. Another factor to be noted is the number of trees per acre, No. 3 containing far too many for its age, nine years. The chief influence on the yield, however, to be gathered from our figures, is that of elevation. Detail as to soil, exposure, &c., are unhappily not given.

The Government ratio of 45 cubic feet to one ton seems to be far under the mark, as this gives very nearly 4,500 lb. dry weight per the usual stack of 100 cubic feet. With timber under ten years, the average

runs according to our experience to 3,500 lb. per 100 cubic feet or 64 cubic feet per ton. Naturally the younger the trees, the lighter the stack, for it is certain that the cubic space occupied by the stack certainly does not represent 100 solid cubic feet of timber owing to the interstices between the logs. The actual weight of a cubic foot of dry blue-gum timber runs out, it is true, to the Government standard of 45 lb. We mention this to warn planters basing the actual dry weight of the fuel they grow by such a high standard as 45 lb. per stacked cubic foot.

A query was recently propounded as to whether it paid better to buy or grow one's fuel for firing purposes. This depends of course on the price of the outside fuel available and on the quality of the reserve land on the estate. The annual yield in lb. of fuel per acre of gums varies from 10½ thousand pounds at say 6,000 feet to 20¼ thousand pounds at say 7,000 feet. Or say the plantations were cleaned felled in successive plots each five to six years' old, the yield would vary from 70,000 lb. to 105,000 lb.

Any further information that our correspondents may furnish will be gladly welcomed.—*Planting Opinion.*

PLANTING NOTES.

FORESTS.—The following table of forest distribution in several sea bound countries, from which a fairly reliable data is given may be of interest, says Mr. D. Forbes in the *Hawaiian Planters' Monthly*:—

Countries.	Percentage of Forest area total average of country under forest.	Population per head of in acres.
East India (British) ..	25 %	5
U. S. America ..	17 "	7-6
Russia in Europe ..	42 "	6-1
Sweden in Europe ..	35 "	9-1
Germany in Europe ..	26 "	8
Italy in Europe ..	22 "	5
France in Europe ..	16 "	6
Germany in Europe ..	4 "	1

POOR QUALITY OF CEYLON TEA.—An Up-country Visiting Agent writes to our evening contemporary:—If most planters began to pluck fine, there would be a plethora of fine teas, which would be, a way, a drng in the market, while the few who continued to pluck coarsely would score considerably. There is a demand for different kinds of tea at different times, and it has paid of late to pluck coarsely to meet the demand for a particular kind of tea. As for the falling-off in quality in March, April, and May, and the consequent drop in the market, it is due in my opinion to the weather, which affects the sap in the tree, and, when the rains set in, the leaf improves at once, and prices rise. Fine plucking will not alter this. I have always held that the market would be relieved and prices steadied by planters going in for making green teas for America on a big scale, and that the Thirty Committee should financially assist for a twelve-month those who would do so. The Committee have lots of money, and this method of spending it would be quite as beneficial as subsidising traders in America and Russia to build up big business for themselves." As to the "expert and tea rejection" scheme, it would require legislation before it could be carried out, as there is no law at present to prevent the tea planter shipping any rubbish he likes. Of course, if tea is bad enough, and we hear of tea bought in Colombo for ten cents being shipped home, the rejection ought to take place at the British Customs. Tea unfit for human consumption is rejected now in America as well as in Australia, and the same vigilance ought to be exercised in England. But the English tea-drinker appears to be able to consume what is too bad for any other country. Surely the Ceylon Association in London might wake the Customs up, as rejection on the other side would be much more easily carried out, and a less invidious duty, than if done in Colombo. Otherwise, we think something should be done on this side.

CEYLON TEA IN RUSSIA.

We give prominence to the following interesting letter addressed to us by Mr. J. M. Maitland-Kirwan from Moscow. Its perusal will whet the general expectation for Mr. T. N. Christie's Report and advice as to the future campaign in favour of our tea in Russia:—

Moscow, Dec. 10, 1897.

DEAR SIR,—You will no doubt be interested to know what the position of Ceylon teas is in this country, and you will shortly have the report of Mr. Christie, whom I have had the pleasure of meeting on several occasions.

The enormous duty of eighty kopecks (1s 10d) per lb, together with many other restrictions, of which Mr. Christie's Report will inform you, tends heavily to hamper the budding of a new product, especially so in this country, in regard to Ceylon tea, where "Russians" have such a firm grip of the palate. Nevertheless, it is most encouraging to know that, in spite of such difficulties, the imports of our teas have risen during the last six years to close on 4,000,000 lb. and this, you may say, with practically no Advertising. I have been going mostly closely into matters during the week I have been here, and I am of opinion that a good round sum of money, spent judiciously in Advertising, would be a well-invested capital. I am afraid Mr. Christie does not altogether adopt my view as to this, but, nevertheless, with every deference to his excellent judgment, that is my undoubted opinion. Mr. Rogivne has done good work here; he has had a hard uphill game to play, and has played it honestly and well, and is now rewarded as he deserves, by having an uncommonly good business at his back. We want more "Rogivnes" out here; there is plenty of room for them, and we shall no doubt get them in time, but assistance will be required to enable such to start, and to this the "Thirty Committee" will doubtless give their careful attention. It is certainly a most important matter and worthy of their gravest consideration.

Weather here is intensely cold, though the sun is shining, and clothed as you are from head to foot in fur, the icy air still finds its way in and makes one sometimes long for the balmy breezes of a certain isle far away in the gorgeous East.—Yours faithfully,

J. M. MAITLAND-KIRWAN.

We are as firm believers in Advertising as our Correspondent; but we doubt the wisdom of starting more "Rogivnes" as opponents of Russian tea-dealers—cannot Ceylon planters work through the latter? Mr. Christie may tell us.

TEA PLANTING IN ASSAM:

THEFTS OF TEA—BREAD AND LIQUORS:

(Notes from a Correspondent.)

What you wrote some while ago about the local consumption of tea, was very interesting. Our case here is very much the same. While nearly every native now-a-days drinks tea, it is not procurable in the open market. The amount of tea sold locally, on the gardens, is very small, so the pilfering that goes on in every factory must be enormous. Any cooly going to the village to buy rice or dhan (paddy) can always barter tea for these things or any little necessities he may want; it is a beautiful system, naturally beneficial and free from all worry and waste of time, tea, unlike cash, being procurable whenever wanted. I have made several ineffectual attempts

at different times to buy tea, but the khyahs will not sell me any for fear I might make enquiry as to whence it was procured.

It seems rather hard lines that the coolies should always select the best tea for their simple transactions. If their pilfering was confined to the coarser grades, one would not mind so much, but they have not the decency even to take massorted teas. In the numerous cases of theft on gardens, so far as I have seen, the tea found in the cooly's possession has been almost invariably of the best grades; taken away from the factory by a woman, or her child, as she was suffering from fever!

How do you make bread in Ceylon? I cannot get my servants to make it without yeast; they say it is impossible. Natives of course make use of the country grog, which is said to be made from the flower or fruit of the "mahwah" tree; but a paid servant cannot debase himself to use such stuff. It is imported into the district by the "sharab maholdars" or liquor-shop keepers, but it has an overpowering smell, enough without any of its adulterants to make the consumer drunk. I should think that "lao pani," fermented rice liquor, would be a good substitute for yeast. It is a glorious beverage, so I have been told, but the Government in its inscrutable wisdom has made its preparation an offence in order to realize a noble revenue from licensing liquor shops. If the natives wish to get drunk it must be done on spirits "recommended by the (Government) faculty," not on a simple, unsophisticated beverage at 8 annas a bottle!

COFFEE, RUBBER AND TOBACCO IN

COSTA RICA:

THE SARAPIQUI ESTATES CO., LD.

The Sarapiqui (Costa Rica) Estates Co., on whose property Mr. J. L. Shand made so favourable a Report, afterwards joining the Board, has issued its first Report. Besides Mr. Shand, two other well-known Ceylon men are Directors, namely, Messrs. J. H. Thring and R. P. Macfarlane, their colleagues being three city merchants, Messrs. Jennings, Maguire and Phipps. With a capital paid-up of £46,756 (£40,000 being the cost of the property which includes an immense area of fine land besides 144 acres of good coffee), the Directors are very properly going to work cautiously and judiciously. The following is from the first Annual Report:—

Work on the Company's plantations has been diligently prosecuted, and considerable progress has been made. The 128 acres referred to in the Prospectus as being already planted have on re-measurement turned out to be 144 acres. This area has been thoroughly cleaned and weeded, and part of it is bearing crop. In addition some 400 acres have been taken in hand and are being planted with coffee. The quality of the coffee has been established by a sample shipment which arrived in July and was sold in September at an average of 96s per cwt, part having realised 108s. Considering that this coffee was defectively cured, owing to the want of proper machinery the result must be considered satisfactory.

It is the desire of the Directors to proceed with the cultivation of Tobacco and India-rubber, and the realisation of the Company's large Estate in timber so soon as funds and the exigencies of work permit; but it is their opinion that for some time to come it will be necessary to devote the resources of the Company both in money and energy to the development of the coffee land.

It has been arranged for a Member of the Board, Mr. R. P. Macfarlane, who has great experience in coffee planting, to visit the plantations, sailing by the Royal Mail Steamer of 12th January, and with him will

go ont an assistant to Mr. Rothe. The heavy outdoor duties require all the Manager's time and attention, and very much interfere with the necessary work of accounts and stores, hitherto attended to by him personally.

As an experienced, shrewd and thoroughly reliable coffee planter, the impressions and report of Mr. Macfarlane on the Costa Rica estate will be looked for with much interest. The Directors are doing wisely in devoting some attention to other products, especially to tobacco (for which their rich soil is suitable) and to rubber for which the demand steadily grows year by year. The Secretary this Company, Mr. A. G. Beeston, has an old connection with Ceylon, his father having been Secretary and Agent to the first Ceylon Railway Company and resident here in Sir Henry Ward's time; while he himself is a nephew of the late Mr. Geo. Steuart, founder of the well-known Colombo firm. The Chairman, Mr. G. D. Jennings, is much esteemed as a man of high character and prolonged City experience.

PRODUCE AND PLANTING.

PLANTING IN BRITISH BORNEO.—On Tuesday night, at a meeting of the Royal Colonial Institute, Mr. E. P. Gueritz read a paper on "British Borneo." The reason given by Mr. Gueritz for the absence of popular knowledge of Sarawak among the commercial community of London, as compared with that of the native States of the Malay Peninsula, Labuan, and North Borneo, was her inability to compete in mineral wealth with the vast tin deposits of the Peninsula. Trade, which was generally carried on through Chinese merchants, included exports of sago—flour (of which 15,481 tons were exported in 1896), gutta, india-rubber, beeswax, birds' nests, quick-silver, tobacco, rice, rattans, and coal. Attention was drawn to the territory as a field for the planter, and reference made to its success in regard to the production of tobacco, the area of which was being extended. Coffee and coconuts were receiving considerable attention, while manila, hemp and rhea had also been planted, and gambier to a small extent. An experiment in tea-planting was also being made on a considerable scale.

COFFEE MIXTURES.—Dr. Bostock Hill, who is the analyst to the Warwickshire county, in making his report to that body, recently referred to the sale of various kinds of mixtures, and said "there can be no doubt that the sale of these coffee compounds, even when labelled, is a fraud, as the price charged for them is always higher than their commercial value, while the purchasers have no means of knowing how infinitesimal is the quantity of coffee contained. . . . In future legislation I am of opinion that it would be very desirable for all such mixtures to be labelled, and that the label should indicate the proportions of the foreign ingredients." Some of Dr. Hill's confrères made the same suggestion to the Select Committee on Adulteration, but their report states: "After careful consideration of the matter, your committee have come to the conclusion that they cannot support the proposal that the labels on mixtures should set forth the several components of the mixture, as well as the fact of admixture."—*H. and C. Mail*, Dec. 17.

THE CEYLON LAND AND PRODUCE COMPANY, LIMITED.

REPORT OF DIRECTORS.

Your directors have the pleasure to submit the annexed profit and loss account and balance sheet for the crop year ending June 30th, 1897, duly

audited. The amount at credit of profit and loss account is £10,356 7s 5d, which, with the sum of £788 5s 9d brought forward from last year, leaves £11,144 13s 2d to be distributed. On July 22nd last an interim dividend of seven and half per cent on the ordinary shares and three per cent on the preference shares was paid, and your directors now propose to pay on December 31st, 1897, the balance of the fixed cumulative dividend on the preference shares (three per cent), making six per cent for the year, and seven and half per cent on the ordinary shares, making fifteen per cent for the year, and, in addition a bonus of five per cent on the ordinary shares—all free of income-tax. It is also proposed to reserve fund, increasing that account to £10,500, and carry forward the balance of £1,438 13s 2d, subject to the directors' remuneration for the year under review, to be fixed at the general meeting, and to the payment of income-tax, &c. In accordance with a resolution of the board, a call of 10s per share was made upon all members holding ordinary shares upon which only £2 10s had been paid, and the same was payable on January 1, 1897. In pursuance of the terms of the notice, the dividend and bonus will be calculated as from the date of receipt of cash. It is a source of gratification to your directors that they are again able to lay before the shareholders evidence of the continued success of the company, notwithstanding the increased cost of production, mainly due to the rise in exchange. The crop of tea greatly exceeded the estimates drawn up at the commencement of the financial year, but the forecast of the cocoa crop was scarcely realised, owing to a very heavy rainfall in December last. The prices obtained for tea were lower than those recorded in the previous period, but it is pleasing to note that a substantial rise in the values of cocoa has been realised.

TEA.—The expansion in the trade in Ceylon tea is indicated by the increasing quantity offered at auction here during the eleven months from January 1 to November 30, which was 1,082,700 packages, realised at an average price of 7½d per lb, compared with 8¼d per lb obtained for 962,000 packages in the same period last year. It speaks well also for the popularity of the article that deliveries fully kept pace with the increased supply, so that the bonded stock in London was 1,000,000lb less on the 30th ultimo than it was a year ago. Quality has varied a good deal, probably due to climatic influences. On the whole the crop has been of a useful description, though the fine flavour, which was at one time the feature in Ceylon tea, is not now so often noticeable as formerly. Common to medium grades ruled about steady through most part of the year, due largely to the growing demand for "leafy kinds" for the Continent and other quarters outside the United Kingdom.

Fine and finest generally met with good competition, but prices showed some irregularity at times, being much influenced by the fluctuations in quality noticed above. Business from London to Russia, the Continent generally, as well as to Canada and America, continues to increase, and exports to these countries bid fair to become a very important feature. Total shipments for the first eleven months of this and the two previous years to November 30 were, according to the Board of Trade returns:—1897, 9,590,000 lb.; 1896, 7,418,000 lb.; 1895, 6,535,000 lb.

Cocoa.—It is a satisfaction to your directors to report that the sales of our crops have been at enhanced values on those of last year, and we have to look back to 1894 for similar prices. By judicious handling, your directors were enabled to finish the realising up to 85s, which is the highest figure obtained this year. The outlook for the article is hopeful, but a return to the high values existing previous to 1894 is improbable.

COFFEE.—The small crops from the company's estates have been disposed of at the best possible prices, but the prognostications of your directors given in

last year's report, pointing to a further reduction in values, have been realised beyond their expectations. The price secured in February for good yellow Liberian was 70s, but in September only 54s 6d was obtainable, and although it is satisfactory to your directors to report that these were extreme at the time they regret that prices have had a further decline, and the value now is about 42s per cwt. The prospect for this article is not promising, on account of the large increase in the production of other countries, especially of Brazil, and we have to refer to the years 1885 and 1886 for similar values.

ACREAGES.—The following statement shows the approximate acreage of the company's properties at date:—Tea, 2,232½; cocoa, coffee, coconuts, etc., 1,582; forest, grass, chena, abandoned, etc., 1,341½; total acreage, 5,156½.

The crop prospects for the season 1897-98 appear to be, so far, favourable, and according to the last reports received from the chairman—who is presently in the island—the estates were in excellent condition. Mr. William Keiller, by rotation, retires from the directorate, but, being eligible, offers himself for re-election. Mr. James B. Laurie, the auditor, also retires, but he is eligible, and offers himself for re-election.—*H and C. Mail*, Dec. 17.

THE CEYLON PROSPECTING SYNDICATE LIMITED.

10 ST. SWITHIN'S LANE, E.C.

Report of the proceedings of the Annual Meeting, held at the Company's Offices, 10 St. Swithin's Lane, E.C., on Wednesday, 1st December, 1897, Mr. A. W. Lawder, M. Inst. C.E., F.G.S., in the Chair. The Secretary read the notice convening the Meeting.

The CHAIRMAN said:—Gentlemen, In rising to address you today, I am sorry that I have to do so in place of Mr. Wallis, the Chairman of the Company. Unfortunately he has been summoned to attend a jury this morning, and is therefore unable to be with us. He expresses his great regret at this, as he always has the interest of the Company at heart. The Directors' Report and the Balance Sheet have been circulated and are in your hands, and in rising to move their adoption, I would like to make a few remarks. Since the Statutory Meeting, held in this room, considerable progress has been made with the Company's business. At that time we had acquired the option for certain lands in the Island of Ceylon, and the rights to the patents for machinery to work them. We have since then exercised that option, and have become landed proprietors in the Island of Ceylon, being now in possession of 191 acres of freehold property. We have also been busy in the exercise of our patent rights, and have had manufactured for us a large and powerful plant, capable of dealing with the alluvial gravels of the Island in a way they have never been dealt with before. The land we have is acknowledged on all hands to be good gemming land, and as we have made up our minds, I think wisely, to commence our work on a large scale, and in a vigorous manner, there is no room to doubt that the operations of the Company must be successful. Our machinery has been on view and at work during the course of last month at Westbourne Park, and invitations to see it were issued to our shareholders, and to many other gentlemen interested in the subject, who were agreeably surprised at the power and suitability of the plant, and the efficiency with which it did its work. I may state that it has fully realised all expectations, and notices of a highly satisfactory nature have appeared in the technical journals. With regard to the Balance Sheet, there is not much in the way of explanation to be said. You have the figures and the Board will be very pleased to hear any remarks, or to add any explanations on points arising that may suggest themselves to the Shareholders. It will be noticed that we still have some shares to place, and I may say

that it is the policy of the Board to obtain further subscriptions for these, rather than to make further calls at present on those already taken up. I may add that we have with us to-day a Shareholder who knows our property well, and being thoroughly conversant with the Gemming industry in Ceylon, I will ask him a little later to make a few remarks on the subject. I now, Gentlemen, beg to formally move that the Report of the Directors and the Balance Sheet be adopted.

Captain H. L. PILKINGTON, a Director, said:—I rise to second the Resolution moved by the Chairman that the Report and Balance Sheet now before the meeting be adopted. I think we have done excellently when we consider the two great difficulties under which we have had to work; the difficulty of developing new machinery, and that of taking up an industry that has not up to the present been successfully worked by an English company. Should we prove successful in our work, we ought to have a very big thing indeed before us. The possibilities of the Gemming industry in Ceylon are almost unlimited, and as we have the sole right of using Mr. Lockhart's machinery in the Island, I regard our position as most favourable. We have a first-class freehold property in Rakwana, the great gemming district of Ceylon, we have plenty of water, and, above all, we know, by the very successful working of our machinery at the recent trials, that the gems in the alluvial to be treated by our plant will beyond doubt be secured, and that we shall not be in the hands of the natives as other companies were.

Mr. ARNOLD FRANCKE, a shareholder, asked for information as to the number of shares taken up, and the amounts paid on them, and some discussion on the subject ensued, the result of which was that the shareholders, with the desire to strengthen the hands of the Directors, expressed their opinion that any outstanding subscriptions should be energetically followed up and payment forthwith secured.

Mr. FRANCKE then said that his inspection of the plant the Company was sending out to Ceylon, had afforded him much pleasure; he fully endorsed all the Chairman had said as to its efficiency and the strength and excellence of its manufacture, and he considered that with such a plant the Company had every prospect of success before it. He wished to lay particular emphasis on the wisdom of the policy of the Directors in deciding to commence vigorous operations at once on a large scale. Past undertakings of a similar nature, both in Ceylon and elsewhere, had failed through the endeavour to work at first in a small and tentative manner with the mistaken idea that encouragement would be gained before facing the necessary outlay for plant adequate to ensure commercial results. He believed that encouraging results could never be obtained in this way, while expenses were all the time running on. It was far more prudent to commence with plant capable of making a return on the capital which would have, in any case, to be laid out, and thus put the success or failure of the enterprise beyond the possibility of a doubt in a short space of time. This course the Directors have decided to pursue.

Mr. LEOPOLD DAVIES spoke as to the necessity of all the shareholders loyally supporting the Directors in an enterprise of this nature, and in paying the calls on their shares promptly, so that the Directors might not be hampered in their use of the Company's working capital, and that the burden of providing it might fall equally on all. He also put a question with regard to the Directors' fees.

Mr. DUNCAN DAVIDSON, one of the Directors, in replying to the question as to the Directors' fees pointed out that they had not been drawn, but that he considered that Directors who gave their time and attention to the Company's business,—and he would like to say that this Company made very considerable demands in this way, which were cheerfully and promptly responded to,—were fully entitled to at least the small sums provided for by the Articles of Association, and that, as soon as the Company's finances warranted it, he was of opinion that they should be paid.

Mr. M. E. WESLEY called attention to some points in the Balance Sheet, noting that he had accounted for all the funds at the Company's disposal, with the exception of a sum of £350 and asked if the Chairman could offer any explanation on the subject.

The CHAIRMAN replied that the £350 to which Mr. Wesley had referred was the sum mentioned in the Prospectus as the cash consideration for the benefit of the Option for the Land, since exercised, and for the Patent Rights. Although not specifically mentioned, it was actually included in the balance sheet and accounted for to the satisfaction of the Auditors. He then asked Mr. F. L. Shand, if he could give the meeting any information as to Gem-mining in Ceylon.

Mr. F. L. SHAND, on rising, said he had spent 15 years in Ceylon, and knew the district in which the Company's estates lay thoroughly. He had been engaged in gemming on lands immediately contiguous to them and, referring to the map on the wall, he pointed to "Golden Grove," "Everton" and "Ran-weltenna" as properties well worth the Company's attention, and he said that it would be important to ascertain whether the surface illum or gem-bearing gravel, which existed there and was very rich, extended over the Company's land. He believed it did. This gravel bed was well known in the district to be very rich. The best gem-bearing gravel is usually found in level country, and not where you have abrupt hills. He instanced a case in which he found a small patch of the surface illum which had escaped denudation on the hill-side owing to its being protected by the roots of a few tea-bushes, out of which he washed gems to the value of 500 rupees. He would like to know what reports on the Company's property had been obtained, he, however, had no doubt that, situated as it was, the illum there might be valued at fully 10s per ton. He had known £7,000 worth of stones sold at one time as the result of three months' ordinary basket washing in this district. The beautiful gems in the case on the table were, he could see, Rakwana stones and of high value. He had once picked up a gem in the district, by the road side, which sold for 500 rupees, and he had sold other Rakwana Sapphires at £10 per carat.

The MANAGING DIRECTOR said that he was particularly pleased with the remarks which Mr. Francke had made as to the advisability of commencing work on a large and comprehensive scale, and with regard to the machinery he was well satisfied that it would accomplish the work necessary to ensure the success of the Company's operations. Referring to Mr. Shand's remarks, he said that the Company's ground had once been the bed of a lake, and was quite flat. It was well known that layers of rich illum existed in it, and the alluvial had been proved to a depth of 138 feet by a shaft sunk by the former proprietors. In reply to the question that Mr. Shand had put as to the Company's property, the most convincing report possible was the case of beautiful cut stones which he held in his hand, and would pass round for the inspection of the Shareholders. These, and many more like them had been found during the sinking of the shaft referred to. Sapphires of such quality were very scarce in the market and never commanded better prices than at the present time. As to the question of working the illum, it was not his intention to do much in the way of selection of the ground, but to pass everything that came to hand rapidly through the machinery. His experience in actual gem-mining, was that valuable gems were constantly found in ground adjacent to the recognized gem-beds, and he had found it most economical to take the ground very much as it came, provided operations could be conducted on an extensive scale.

The CHAIRMAN then announced that the adoption of the Report and Balance Sheet had been proposed and seconded, and he put the Resolution to the meeting. It was carried unanimously.

Mr. FRANCKE then proposed the re-election of the Auditors, Messrs. Ball, Baker, Deed, Cornish & Co.

for the ensuing year. This was seconded by Mr. Pallett and duly passed.

A vote of thanks to the Chairman for presiding at the meeting, was proposed by Mr. Edwd. J. Sargeant, and seconded by Mr. E. Wright, and the proceedings terminated.

AIDS TO AGRICULTURE IN CEYLON.

In commenting lately on the vast increase there would be in the production of Coconuts—valued at from R1,400,000 to R2,100,000 a year,—if the average on 200,000 acres be increased only by 5 nuts per tree, per annum, we declared that neither the Government nor the public had ever awakened to a proper sense of the importance and capabilities of the great Coconut Planting Enterprise of the Colony. By the public we meant, of course, the public as a whole; for individual members of the community—now an upcountry planter, then a Colombo merchant; now a lowcountry planter, then an enlightened retired Sinhalese public servant—as our columns, and specially the pamphlet on salt we recently published, show, have fully realised the immense gain there would be to coconuts specially and to the country generally, if salt were rendered available for agricultural purposes. Their efforts to move the Government were, however, unsuccessful; and it is not alone in connection with the question of salt that local authorities have failed to appreciate fully the importance of agriculture to the welfare of the whole country. This island is essentially agricultural, whether we regard the indigenous population, who have, from time immemorial, considered the cultivation of the soil as the most honourable industry, or the colonist, who has brought capital into the country to test its capabilities for coffee, cinchona, cardamoms, cacao, tea, rubber, and other products. Agriculture, therefore, is the mainstay of the island, the backbone of its prosperity; and yet, how grudgingly does the Government extend any help to the agricultural interest! We by no means assert that the planter, whether European or native, should be regarded as a disinterested philanthropist, and that he should be aided at every turn from the public funds, instead of being expected to help himself in the royal way which ensures a blessing. But what the Government too often forgets is that the planter—we use the word in a sense to include every agriculturist—is a public benefactor, in that, while he benefits himself, he in some way, and generally according to the measure of his success, benefits the country; that there are directions in which the Government can aid him, almost without any effort and almost at no cost to itself; that there are circumstances under which its help becomes an urgent duty, especially under conditions in which its influence and resources can command scientific knowledge and experience not readily available to the individual. We can recall the refusal of our Government a few years ago to avail itself of Mr. Ernest Green's services for work specially recommended by the Planters' Association; and it was rather grudgingly that, recently, official recognition was given to the same gentleman with a certain status as Honorary Government Entomologist, as if, in a little colony like this, every encouragement should not be accorded to those who develop a most uncommon, and yet most useful, aptitude for

patient scientific investigation. And then, after some show of readiness to help the cacao planter,—for which thanks are due to Sir West Ridgeway,—there has been a rather mysterious withdrawal, which has placed on a few private proprietors the obligation of securing the services of a Specialist to investigate a trouble in which every cacao plantation, large or small, is interested, and therefore the country generally. For, our cacao exports now represent a value approximating to one-and-a-half million of rupees annually. We do not underrate what Mr. Willis is doing to further knowledge on agricultural subjects, including the cacao pest; but he has proceeded rather on his personal initiative than at the instance of the Government. What we deprecate is the tendency of the Government to take too narrow a view of its responsibilities and duties, to look only to the immediate present, and to favour a strictly rupees-and-cents view of every question, even in regard to such comparatively light matters as the employment of a Scientist involving an outlay of five or six thousand rupees per annum. When the Island was under the cloud of depression, the Government added to the burdens of the taxpayers. That was, perhaps, in a way, inevitable; but it proceeded on the assumption that the best way of increasing the revenue was by the simplest expedient of doubling certain levies. Of course, its anticipations were not all realized in connection with the revenue from Stamps and Customs. Not only so; but an impulse was given to Crime, for when impoverished people found resort to the Courts to establish their rights rendered more difficult, they began taking the law into their own hands. The chief grievance, however, is that when prosperity returned to the island, there was no reduction or removal of the special levies. But rather, a new engine of taxation has been found—which many think will be widely used, should “depression” recur—in increased Railway fares. Take again the entirely unjustifiable enhancement by Sir Arthur Havelock of the Kerosine Oil Tax, to meet a contingency of his own creation. The apprehended deficit in the revenue did not happily arise from abolition, but when a reduction was applied for, and the interests of agriculture were specially pleaded in connection with oil engines which are a convenience on tea estates which have no firewood available, there was any amount of quibbling in order to escape an obvious obligation. Now, a reduction has been tardily granted, but applicable only to oil used for machinery!

But to return to the question of Salt, the revenue roughly makes a profit of R2 per cwt. a year on 450,000 cwt., or say a net annual average of R900,000 by the monopoly. The production of a larger quantity cannot inconvenience in the least the Government which has the work chiefly done by contract, and has to arrange only for receiving the salt into its stores and for issuing the same. The probability is that the contract rates can be lowered for larger collections. The only reason advanced, in the past, against issuing salt at a cheap rate for agricultural purposes was that it could not be effectually denaturalized. The Ceylon Government was content to wait for an article that would render adulteration perfect, and it has renewed its refusal to help local agriculture during the 30 years that Germany has been strengthening the hands of her agriculturists by the issue of cheap salt. We

have already expressed our thanks to the Government for the tardy and round-about concession of a Salt Committee; but we hold that, even if it is impossible to denaturalize salt, the Government would lose nothing by the concession. Assuming that the wealth of local Coconut produce is increased to begin with, by only R1,000,000 a year, would the planters concerned, be able to avoid contributing at least 1 per cent of their profits to indirect taxation? That would represent R10,000 a year—a handsome insurance against any loss from the use of cheap salt for culinary purposes! But it is not for coconut land alone that cheap salt would be used. Other cultivators would benefit by it, while salt would rid land of grubs and other insect pests, and cattle would thrive on a free exhibition of salt and be protected against disease. We bespeak, therefore, for our local Agriculture, not alone as touching salt, but in every way, a far more considerate and sympathetic treatment at the hand of our Government, as its truest wisdom.

AN AGRICULTURAL COLLEGE.

Ceylon is far ahead of the Straits in one respect, it possesses an Agricultural College, where we understand, several schools are being conducted, amongst which are those specially devoted to the separate education of students in agriculture, veterinary, science, forestry, and dairy-farming. Quite recently a technical school has been added, with, it is said, the brightest prospects of success. Now if there be any particular knowledge of more value than all others in the Straits, it should be that concerning agriculture and forestry. And yet, there is no establishment or institution, of even the most humble character, where the local youth can acquire any scientific training in reference to those two important subjects. Consequently, the Straits aspirants to knowledge in that direction must needs go elsewhere, and, Ceylon being not far distant, they naturally migrate there for a season of instruction. One of these students, Mr. A. R. Jeremiah, has achieved the latest success, and it is about him that a Ceylon contemporary has been pleased to say a few words of well-deserved commendation, which we give elsewhere. Of the ten prizes, offered for competition at the Agricultural School, this youthful Scientist has secured those for (1) Senior class 1891, for proficiency in Agriculture. (2) Agricultural Chemistry and (3) Dairy Work given by the manager of the Dairy. He has been also awarded a first-class certificate for 1897. We congratulate both the student and his family; the former on having made the best use of his time at College, and the latter on having had the good sense to permit the youth to do first a profession suitable to his tastes, and to send him though probably at considerable expense, to the best available source of knowledge on the subject, required to be studied. Everybody knows how staunch a supporter technical Science had in Sir Cecil Smith, and we presume that the present Governor is no less ready to do all that might be necessary to promote the success of an institution devoted to the study of that and kindred sciences. Yet if the Straits Settlements and the Native States, are even to have Schools for Agriculture and Forestry the first movement in that direction must come from persons intimately associated with the practical side of the question. We must, therefore, look to Messrs. H. N. Rildey, C. Curtis, Leonard Wray, A. B. Stephens and Robert Derry and the numerous planters around us, to take the initiative, feeling sure that, afterwards the several Governments in Malaya, if properly approached, will be easily persuaded to do all that may be required of them towards establishing an Agricultural College on lines suggested by the experts we have named.—*Penang Gazette*, Dec. 22,

TEA CULTIVATION IN CEYLON:
OUR HEAVIEST-BEARING PLANTATION—
MARIAWATTE—BEATING THE RECORD.

We are indebted to Mr. H. V. Masefield, Manager of the Ceylon Tea Plantation Co. in the island, for the figures of crop, and bearing per acre, realized by the Company's far-famed Mariawatte garden for last year, as compared with the returns previously published;—

Revised statement of yield of Mariawatte old tea from 1884 to 1897 showing average per acre, also yield of whole estate for six years showing average:

OLDEST AND SPECIAL FIELD.—Actual acreage in bearing 101 a. 1 r. 0 p.

Year.	Made tea. lb.	Yield per acre, lb.	per acre.
1884	109,230	1,078	
1885	117,842	1,163	"
1886	105,925	1,046	"
1887	115,996	1,145	"
1888	106,410	1,050	"
1889	113,834	1,124	"
1890	140,144	1,384	"
1891	120,366	1,188	"
1892	119,909	1,184	"
1893	115,440	1,140	"
1894	110,443	1,090	"
1895	118,560	1,170	"
1896	113,360	1,119	"
1897	105,729	1,044	"

Average for above 14 years 1,137 lb. per acre.

YIELD FOR THE WHOLE ESTATE.

Year.	Actual acreage in bearing 458½ acres. lb.	per acre.
*1892	643	
1893	817	"
1894	760	"
1895	886	"
1896	896	"
1897	926	"

Average for above six years 821 lb. per acre.

* Atgalla crops having been included prior to 1892 figures are not available.

We congratulate the Company, Mr. Masefield, and the Acting Superintendent of Mariawatte for last year (Mr. C. M. B. Wilkins) on the splendid result. It will be observed that over the whole estate of 458½ acres, the crop is the largest per acre—926 lb. made tea—ever gathered! It is in fact not only a "record" for Ceylon, but also for "the world." Nowhere in India or Java, we suppose, has 926 lb. (11 maunds) made tea, been harvested over so large an area as 458 acres? If we turn to the oldest field of Mariawatte, planted in 1879 and therefore in its 19th year, we find the crop shows a slight decline, but it still reaches the unprecedented figure of 1,044 lb. per acre for the 101¼ acres, against an average for 14 years of 1,137 lb. The average for six years over the whole estate is 821 lb., while 1897 gave, as we have said, no less than 926 lb. per acre.

TEA CONSUMPTION AND CULTIVATION
IN RUSSIA.

Mr. R. Valentine Webster is surely a man to be envied and admired! Envied for the free scope given to him in travelling over this world's surface as an Agent and Advocate of Ceylon teas, and admired for the "pluck" and enterprise he has displayed in the discharge of his duty and for his special facility in the use of his pen as an amateur "litterateur." Here he is sending to the Ceylon press by far the most graphic and interesting, as

well as instructive letter (see another page) that has ever reached us on the subject of Russia and its tea drinkers and growers. In half-a-dozen years, Mr. Rogivue and his colleagues did not manage to give us so vivid an impression of the country, the people and the "tea situation"; while Mr. Webster's expedition to the Crimea, to Batoum, the Caucasus and right into the preserves of the carefully guarded Government Tea Plantations, is unique and most interesting to every tea planter and tea merchant in Ceylon. As journalists in fact, we are inclined to think Mr. Webster has missed his vocation. He ought to be a special Press Correspondent and to climb up the ladder along which such men as Sir W. H. Russell, Archibald Forbes and Henry Stanley gathered fame. Probably, however, Mr. Webster, is quite content with his own particular calling and most heartily do we wish him the widest possible success in making Ceylon tea known and in extending its sale all over the habitable globe. Nowhere, do we wish to see such sales extend more freely than in Russia. Mr. Webster gives us much reason to expect rapid improvement during the next few years; while his account of the experiment of tea-growing in the Caucasus, shows there is no more to fear from operations in that quarter than in the Carolinas where indeed the climate is far more suitable. We thought the tea-bush a hardy plant when we saw it flushing in the open air in Washington at 39 degrees North latitude; but this is beaten by Mr. Webster's description of a tea field covered with snow! Then again the Chinese employé on the tea garden at £40 a month reminds us of the experience of the Messrs. Worms in Pusselawa in the "forties" when they got a Chinaman over to make tea from their Condagalla bushes; but dropped the experiment when they found the tea made, cost them £5 sterling per pound avoirdupois!

THE CEYLON TEA CROP FOR 1897.

Only at a very late hour as we are going to press, have we been able to get figures from the Chamber of Commerce final Export Return for 1897. We can only give the main results as follows:—

EXPORTS IN 1897.

	Total lb.
Tea for United Kingdom	98,930,059
Tea for Anstralia	13,258,456
Tea for America	830,873

Grand total to all countries 116,054,567 lb.
The first estimate made by the Planters' Association was 117,200,000 lb., afterwards raised to 119,000,000 lb. Messrs. Forbes & Walker fixed their's at 120 million lb., and had it not been for exceptionally unfavourable monsoon experiences, we believe this figure would have been attained, as the best authorities in the island fully anticipated. But both in India and Ceylon first estimates had to be cut down as the year grew older.

PLANTING REVIEW FOR 1897.

TEA.—The past year has not been such a good year for planters as its predecessors. High rates of exchange, dear rice and a lower average of prices in the Local and London markets have upset many calculations. The yield has not been quite so much as expected. Such authorities as Messrs. Forbes and Walker and the Planters' Association made the forecast 119,000,000 lb. The result according to your contemporary, will

be 116,000,000 a little under 3,000,000 lb. Considering the weather, which has generally been antagonistic to flushing, I consider the estimates made by the leading authorities mentioned very close ones. The long-continued wet cold and sunless weather in S.-W. monsoon easily accounts the out-turn very less than expected. Up to July it appeared as if even more sanguine estimators than those quoted were to be true prophets, but the sponge had to be thrown up by end of October. Uva, I believe, will be found most progressive in 1897. The severe S.-W. monsoon in the Central and Western provinces carried moisture clouds into Uva, and this last province had not the prolonged dry showerless weather it generally experiences in the S.-W. Manufacture as a rule was well attended to. If not, it certainly was not the fault of Colombo and London Agents who continually were prodding up Managers of tea estates. I think, however, many factories have not sufficient withering accommodation without which it is impossible to have that fundamental operation in tea manufacture *an even wither*.—As we have had so many obstacles to contend with in 1897, we may have on the see-saw principle a good time of it in 1898 for tea planters: so note it be—

[We have added in the correct export figures in each case.—ED. T.A.]

	lb.	
Exported Tea	1895 ..	97,939,871
Do.	1896 ..	108,141,412
Do.	1897 ..	116,054,567

COFFEE.—The price of this staple has been lower during the past season than it has been for some time. Fortunately, Ceylon is not much affected by this for we have so little to export. The leaf disease is quite as bad in the few acres of coffee left, as it was when we had thousands of acres, so a revival of this product is not likely to take place.

	cwt.
Exported Coffee	1895 .. 63,920
Do.	1896 .. 22,747
Do.	1897 .. 19,383

CACAO.—The disease which commenced to be talked about last season has made such strides, that scientists are now in our midst. Where you have soil and a climate adapted for the cultivation, we have planters who are quite pleased with the returns they get. "Supply, supply, supply" is their motto. Cacao is not like tea or coffee when the old bushes are so close that supplies have no chance. Supply with a hardy variety, and the results, say the favoured cacao planters, are successful. The action taken by the Proprietor and Manager of Wariapola ought to put to shame our lethargic Government, who after repeated prodding at its tough hide, on the part of the Planters' Association, labours like the mountain labouring and with the same result a ridiculous mouse,—munificently designates Mr. Green an Honorary Government Entomologist, and gives him a small honorarium. How differently does the Indian Government act when any of their Agricultural Products are threatened.

	lb.
Exported Cacao	1895 .. 27,420
Do.	1896 .. 31,366
Do.	1897 .. 34,503

CINCHONA.—Alas we have none of this product to benefit by the higher prices now ruling:—

	lb.
Exported Cinchona	.. 1895 921,085
Do.	.. 1896 1,309,560
Do.	.. 1897 653,346

CARDAMOMS.—A limited cultivation, but those who are fortunate to grow the article, look very happy:—

	lb.
Exported Cardamoms	1895 .. 374,635
Do.	1896 .. 452,595
Do.	1897 .. 532,830

OUR STAPLE EXPORTS FOR TEN YEARS AND DISTRIBUTION FOR 1896-97.

We direct attention to the interesting tables given as a *Supplement* last month as compiled from the Chamber of Commerce return. We have already noticed the figures for tea and explained how the increase between 1896 and last year is 3 million lb less than between 1895 and 1896. Our table looks well however with the exports of tea running up from 24,381,296 lb in 1888 to 116,054,567 lb in 1897. As regards distribution, Australasia treats us well in taking 2,200,000 lb more last year than in 1896 (or over a fourth of the total increase). America only shows an increase of 112,000 lb direct but to this, undoubtedly 320,000 lb more entered to "China" should be added. So that America altogether takes direct (apart from U. Kingdom tea re-exports) 1,520,000 lb. The Export to Russia has greatly improved, showing 200,000 lb advance last year and so has that to Germany and to Africa, the latter export now standing at 265,480 lb. Leaving out the United Kingdom, Australasia, India (which continues to take close on a million lb.) America, Africa, Singapore, Mauritius and Malta, we get the totals for the CONTINENT OF EUROPE of tea sent direct as follows:—

	1896	1897	Increase
Tea Exports lb.	617,345	937,529	320,184

Our poor old staple coffee makes a very poor show in 1897, but strange to say the export of 1888 was only twice last year's though in the interval we rose to nearly five times that quantity. Very different is the case with cinchona bark which has run down from 12½ million lb. to 650,000 lb in the ten years. Cacao, on the other hand, shows a steady advance from 13,000 to 34,000 cwt., nearly all sent to London. Cardamoms too have nearly doubled in export in the ten years, the shipments being divided between London and India with an appreciable quantity 30,290 lb to Germany direct. We must leave the more purely native Exports for notice later on, save that we cannot help attracting attention to the grand show made by the products of the coconut palm, more especially in oil, copra and desiccated produce. A thousand pities, that the richest coconut region in Ceylon should not have its railway before seventy miles of unoccupied, uncultivated country which could so well wait!

OUR PLANTING DISTRICTS IN 1897.

Reports from well-known residents in nine additional districts will be found on our third page today, and deserve attention. They range from Madulkelly to Lower Dimbula and from Madulima to Rangalla. It is cheering to learn by the last-mentioned of the faith felt in the future of cardamoms and the probability of an extension of cultivation. The attention of a member of Council is directed to what is said in correction about road-making in the days of Major Skinner by one who ought to know: indeed we can ourselves testify that never was better work done on the roads than during the days of Ceylon's great Road-maker. Criticism of roads

or of official action, and suggestions for improvement will be found in nearly all the Reports—and more especially in that for the Kotagalla division of Dimbula. Motor Cars electrically driven are suggested by a Wattedgama planter, the power being taken off periodically from a storage factory placed near a good waterfall. This is, of course, quite a feasible idea, which may be realised freely in the country by-and-by. It is not pleasant to read how the railway slip sent more of the Uva planters to the Hambantota and Ratnapura cart outlets. Our Gampola reviewer has much to say about the usage and law regulating labour; a higher stamp on "tundus" is a feasible and probably good idea if it kept coolies steadier at work. Fifty-four applications for one vacancy of Superintendent is a big order; but we can quite believe it. North Travancore should take off some more of our trained planters.

PLANTING NOTES.

RAT COFFEE.—W. K. Brooks, the naturalist, in an article contributed to *Scribner's Magazine* some time ago, on "Aspects of Nature in the West Indies," states that the natives of Jamaica claim that their coffee is the best in the world, and that which grows on the sides of the high mountains is the best in Jamaica, for in high altitudes it acquires a rich flavor, which commands the highest prices in the English market. We are told, however, that the quitenessence of all the *rat coffee*, or the seeds from berries which have been gnawed by rats, for these animals are very fond of the aromatic pulp of the cherry-like fruit which encloses the seeds; and as their fastidious taste leads them to select the best, children are employed to gather among the bushes the berries which they have gnawed, and this coffee is set apart as the finest and most delicious of all.—*American Grocers' Journal*.

CACAO CULTIVATION IN CEYLON.—We omitted yesterday to call special attention to the excellent and re-assuring letters from practical planters in answer to the London paragraph of a Ceylon cacao pessimist which we quoted the other day. We were of course aware of the old trees in Peradeniya Gardens, in Kandy town, and in front of the Palakelle bungalow; but a few detached trees growing in this way cannot be taken as a fair test of a field or "cacao walk." Still it is quite evident from what our correspondent says that there is no reason to fear dying out in the latter case when proper land has been selected and the plants put in and treated judiciously. The very fact that our export in 1897 shews so large an increase—15 per cent above that of 1896—may be taken to indicate that "the cacao industry" has come to stay with us.

THE CEYLON LAND AND PRODUCE COMPANY.—We can do no more today than call attention to the summary of the Directors' Report for this Company. It is a very full and extremely satisfactory document, and we congratulate the shareholders on once more getting 15 per cent of dividends—a rate that has continued without interruption since 1892 and this notwithstanding that cocoa has fallen from 96s 5d. average per cwt. in that year to 66s 1d. in 1897 and tea from 7-81d. to 6-51d. per lb. The crops have however, increased: cocoa from 1,431 cwt. in 1892 to 2,266 cwt. in 1897 and tea from 503,293 lb. (average 364 lb. per acre) to 748,994 lb. (average 476 lb. per acre) in the same periods. Mr. James Wilson, the Chairman, of this prosperous Company is now in Ceylon and he reports favourably on the prospects of 1897-8.

CINCHONA PROSPECTS.—A Java correspondent writes as follows about Cinchona:—

"Cinchona continues to rise, the price of the unit being per last telegram 7 cents (1 2/5d) to 8 cents (1 3/5d) at the Amsterdam auction, and higher rates being realized for lots sold privately. This is a big rise from 2 1/2 cents in March of this year, and thanks alone to the starting of two Quinine Factories out here, which have for the moment broken the back of the German ring, who for the last 4 years have made the price just what they liked."—Batavia, Dec. 15.

THE RAGALLA TEA ESTATES, LIMITED.—The Directors' Report dated 24th December last will be found on another page and affords very full information respecting the Company and estates. Dividends were paid up to July last; but for the current year, the Directors report they cannot declare a dividend on the ordinary shares. They are, however, very sanguine about prospects in the near future with young tea coming into bearing, a new factory, &c. Certainly Ragalla and Kellburne are both very valuable properties, and ought to do well.

A NEW PRODUCT FOR EXPORT.—Not long ago we stated that there was a good business done between Colombo and the Persian Gulf ports in coffee husk, which was practically refuse thrown away by planters after pulping and cleaning the coffee berries. The Arabs, especially, make use of the husk in place of the civilized preparation of *café noir*. We now hear that, besides coffee husks, dried cardamom husks have a marketable value, and that shipments of these are being made to some Continental ports. In grading the cardamoms, the "splits" are utilized for this purpose after "seeding" them, and the husks can be placed on the market without being thrown away as refuse. Planters would do well to note this fact, and, in sending the different grades, to add "husks" to the existing classification.—Local "Times."

"THE AGRICULTURAL ANNUAL AND MARK LANE EXPRESS ALMANAC for 1898" has just been issued from the office of this world-known journal. It contains, as in former years, a series of articles on topics of interest and profit to farmers, the contributors being experts in their different departments. Amongst the more notable will be found one entitled "Can the Empire Feed Itself?" by Mr. C. Kains Jackson; "Malt and Manure," by Mr. H. Stokes; and "Extended Stock Farming as a remedy for Depression," by Mr. J. Darby. The importance of "Chemical Analysis" to the farmer is pointed out by Mr. A. E. Sibson, and Mr. T. Ironmonger describes, "The Position of Foreigners in the Hop Field." An important contribution is one on "Teat Troubles," by a Member of the Royal College of Veterinary Surgeons, and Mr. Sanders Spencer explains the great use and profit of "Grass as Food for Pigs." Mr. W. Scarth Dixon describes the "Cleveland Bay, and their Place on the Farm," and Mr. E. G. F. Walker treats of "The Seamy Side of English Dairying." Other topics are "Small Fruit for Small Growers;" by Mr. G. H. Hollingworth; and "How to Combat Foul Brood in Bees" by Mr. C. N. White. Mr. J. T. Critchell directs attention to "Australasian Food Exports to Great Britain," and their relation to the food supply of the Kingdom, whilst Mr. J. B. Simpson contributes an interesting article on the "Future of the Leicester Breed of Sheep." The Editor (Mr. A. J. Stanton), as usual, contributes a summary of "Agriculture in 1897," which will be read with considerable interest, as setting out the principal events of the year. The Annual is well illustrated, and more profusely so than ever, the pictures being up-to-date, including Mr. Wortley's cross-bred steer "General," which took champion prize at the Norwich, Birmingham, and Smithfield Shows this winter. The frontispiece is an admirable portrait of the Rt. Hon. Earl Spencer, K.G., President of the Royal Agricultural Society of England.

The Planting Districts in 1897.**HANTANA DISTRICT IN 1897.**

WEATHER.—On the whole it has been a fair average year. A capital season for planting and supplying though it was perhaps a little late before it could be begun. There has been an absence of very heavy rain; and burst drains, washed away roads, and scoured out ravines, have not been in evidence to any extent; land-wind has been wanting in energy, and not so prevalent.

CROP.—Estimates ought to be secured if they have been carefully made.

LABOUR SUPPLY.—Has been sufficient, and of a good quality.

TRANSPORT.—Many estates have their own carts, and those who have not, had to pay enhanced rates owing to the rise of price in all foodstuffs.

ROADS.—Nothing to brag about, and those in and about Kandy were never worse.

RICE AND OTHER SUPPLIES have been at famine rates pretty much. When the derangement of trade, owing to the plague precautions, had made itself felt in a general advance of price, the situation was intensified by the rock-slip on the railway, and any rag of conscience which the Moormen traders had left was then lost for good. There was no attempt to get a fair profit, and so grasping did the traders become that there was more than one occasion when the kaddies were in danger of being looted. This fear was the only thing that there was to check their capacity, and even with it, what they did demand was unmerciful.

GRIEVANCES.—I have not any. If I were only to think a little no doubt something might come to my mind which might serve as a plaint; but like the nation which is happy in having no history, so is the district happy which has no grievance. But Hantana is not quite that yet. Round about Kandy, there are a number of planters who have to serve on the jury, and too close to town to get any batta at all from Government for their work. When the Court is sitting they have to use their own horses to come in with: when it adjourns for tiffin they have to spend their own money or go without the meal: and if the trial be a long one, and the sitting is late, they have to find their way home in the dark, or pay for hotel accommodation. The Government takes every thing out of them, and gives nothing. They are the hardest-ground section of the jury world which I know of—and deserve some consideration, but get none. A man may during the time he is a juror have to travel 100 miles or more, and get no allowance, may have to eat half a score of Queen's Hotel's tiffins, while labouring for the public good, and have to do it at his own expense: have three or four nights in town, and yet if he asks for batta, or suggests carriage hire, he is smiled blandly at by a Civil Official, and is told the thing is not possible. Why not possible? Ah! that's the rub. It would be difficult to establish the justice of the act, or give sound reasons why the elect few should be so systematically neglected and preyed on.

LOWER HEWAHETA AND HANTANA SOUTH.

WEATHER this year has been favourable.

CROP.—All the year the crop has come in well and estimates were generally exceeded.

LABOUR SUPPLY.—Owing to the district having its own federation, labour seems more settled and the supply seems ample for all requirements.

TRANSPORT has been as usual.

ROADS have been in very bad repair all through the year.

RICE AND OTHER SUPPLIES have been sold at increased rates on most estates owing to heavy prices ruling.

GRIEVANCES have been few and far between; but what have arisen, have been due to arrack.

REMARKS.—The area in tea in this old district must nearly equal the coffee area of the old days.

AMBAGAMUWA DISTRICT IN 1897.

WEATHER generally not unusual for this district.

CROP.—Estimates have been a little short, but not to any material extent. Finer plucking business for it!

LABOUR SUPPLY very good. Advances a bit stiffish; a certain firm alone has to be blamed for this cause, which never existed before.

TRANSPORT AND ROADS.—Roads were never in better order. Great credit is due to Mr. Ward and his staff for the upkeep of roads.

RICE AND OTHER SUPPLIES very expensive. Unless the Chetty and Moormen clique are overcome by some other means it will be disastrous to the tea enter prise to let it go on longer.

GRIEVANCES.—A permanent Magistrate for Gampola and Nawalapitiya a *sine quo non* and medical officers stationed in the district should on no account be taken away to act for others, and this vast district left to the tender mercies of under-strappers, and why do not the Medical Department have a man stationed in every province for relieving duty? Surely he can be well employed when not acting for a D. M. O.

KNUCKLES DISTRICT IN 1897.

WEATHER.—**RAINFALL:**—January 6'48, February 3'55, March 2'08, April 14'40, May 6'05, June 15'15, July 4'80, August 11'03, September 9'01, October 9'5, November 17'51, December.

CROP.—The tea flushed well to June, but the flush has been very short the last six months.

LABOUR SUPPLY.—Short.

TRANSPORT AND ROADS.—Expensive owing to the railway slip and the bad condition of the roads.

RICE AND OTHER SUPPLIES.—Rice has been very dear.

PUSSELLAWA DISTRICT IN 1897.

WEATHER—generally has been favourable for tea. There was a marked absence in comparison with previous years of high wind in the early part of the year. The advent of the South-West monsoon was rather abnormal, but when once clearly established we had some very severe bursts of strong wind which did no little damage. Rain has been more evenly distributed than usual and in comparison with former years considerably more has fallen.

CROPS have been up to the mark and estimates generally secured.

LABOUR SUPPLY has been ample throughout the year, employers generally combining to help one another.

TRANSPORT.—In some cases there has been a good deal of foot-and-mouth disease and carts have not been so freely available at all times as previously.

ROADS are going from bad to worse, and though attempts have been made towards repair, these have been of a very temporary and inadequate character.

RICE AND SUPPLY.—Prices for these have ruled exceptionally high throughout the year, reaching famine prices during the first short period after the Railway slip at Alagalla; Chetties and traders throughout the district taking advantage of the ignorance of the native population in keeping up prices long after the necessity, *so called*, to do so.

GRIEVANCES.—Telegraph station at Ramboda is very desirable. Hospital accommodation and a new dispensary for Pussellawa District absolutely necessary. More adequate grants for upkeep of roads keenly wanted. A resident Police Magistrate urgently required, and the abolition of tolls at Gampola bridge and Pussellawa town longed and prayed for the necessity of such obsolete and barbarous taxation being out of all proportion to any advantage gained in having easy lines of transport communications.

MORAWAKA DISTRICT IN 1897.

TEA CROPS.—Mostly short of estimates, chiefly owing to want of labor early in the season.

LABOR SUPPLY—has been very short on many estates till quite recently, when in common with the

t of Ceylon, we benefitted by the influx from the st.

TRANSPORT.—The improved MacBride system has been responsible for our cart hire going up 25%, but our new District Engineer (Mr. Clementi Smith) is putting matters right. Transport of rice and tea to and from estates not served by roads is a matter of infinite difficulty and great expense.

ROADS.—During this year a grant-in-aid road from Deniya to Anningkanda has been finished, and extension will now be made to Hayes and later on, it is hoped to join the Rakwana road at Lauderdale.

RICE AND SUPPLIES.—The former rose to R5, and was scarce even at that for some time; other supplies have been dear. Supply of meat and bread is indifferent and uncertain.

GRIEVANCES.—Want of a police force and a proper resident headman, also a telegraph station (wire could be taken across to Rakwana, 10 miles). Hospital at Deniya should be finished sharp, as the present system of carrying sick coolies to Mataara is inhuman. The balance of the Government land not required for public purposes should be sold and the country opened up by means of cheap roads, so as to render it available for Tea and other products.

KOTMALE DISTRICT IN 1897.

WEATHER GENERALLY.—The rainfall was about the average, but the N.-E. monsoon was a failure.

CROP.—Most estates were a little short of their estimates.

LABOUR SUPPLY.—Was sufficient except in the very busy months, April and May, when Sunday pluckings for cash had to be resorted to.

TRANSPORT.—Most estates keep their own carts, and as the farthest estate for Nawalapitiya is within 13 miles, no difficulty was experienced.

RICE AND OTHER SUPPLIES.—Always obtainable at Nawalapitiya, except when the slip occurred at Alagalla, then the Chetties, &c., raised their prices to exorbitant prices.

ROADS.—The main road was kept in very fair condition, branch road (Kataboola to Tyspane) especially, the last mile is very bad.

GRIEVANCES.—None that I know of. *Mirabile dictu!*

REMARKS.—Happy and Prosperous New Year to the *Ceylon Observer* and especially to the veteran Editor.

PASSARA DISTRICT IN 1897.

WEATHER.—Rainfall 115 inches.

CROP 2,500,000 made tea, bearing tea 5,821. Total 8,700.

LABOUR SUPPLY 7,000, shortly wanted 9,800 coolies. **TRANSPORT** via Bivella Rail 1.45 cart = 55 = 2 carts.

ROADS.—N. Kula Doomoo Gap Road Madulsima progressing.

RICE AND OTHER SUPPLIES very dear.

GRIEVANCES.—Want of cheap transport.

REMARKS.—Rail charges on rice higher than on tea; shameful simply.

WATAWALA DISTRICT, 1897.

Around here, we are not sorry to say "off with the Old Love and on with the New." A hearty good-bye to Old 1897, as he fast expires! He might have been a good deal worse to us, and he might have been much better. A rather dull uninteresting old chap he has shown himself on the whole.

LABOUR.—To his credit be it said that he greatly improved our Labour Force, so that he leaves our estates, and district roads, &c., in good cultivation and order; but, what he gave with the right hand, he took back with the left; as with his gift of extra coolies, he gave an extra dose of wet and sunless weather which has left its mark on us and our crops.

CROPS.—Talking of crops, a few of the lucky "to-tums" have got over their estimates, as many more have only managed to secure them: while the greater number seem to be just a shade on the wrong side; so, on the whole, the district will probably be found a little, but not greatly, short.

TRANSPORT.—Fortunately, with our ample and good roads, new station at Rozelle, &c., we are able to get our crops off cheaply, and get easily about, when we feel so inclined.

GRIEVANCES.—The one thing we lack, in the way of public conveniences, is a Central Telegraphic Station at the Post Office, to save us having to send to Hatton every time we need to "wire"; and we look to 1898 righting this.

RICE has been abnormally dear, as in other districts; but, now-a-days, with easy transport and facilities for buying from European Importers in Colombo, the planter who pays too much for rice may blame himself chiefly.

On the whole, we may close as we began, and say that 1897 here might have been worse; and had it and its predecessor not taken away so many of our oldest and well-liked neighbours, it should have had a fair place in the annals of "Old Ambegamao."

R. I. P.

TWENTY MILES WEST OF THE PEAK.

Dec. 25.

WEATHER:—

1st Quarter 1897—	32.31 inches.
2nd	68.29 "
3rd	51.29 "
4th	15.37 "

167.26

20 inches above average.

There were 35.19 inches in September, nearly twice the average; October 9.71 or about one-third the average; November 7.20 two-thirds the average.

1897.

Jan. 3.35 in.	July 12.23 above

1897	20.42	12.34	4.26	13.09	13.80

Heavy squalls in S. W. monsoon, especially in July and August. November and December gloomy.

CROP.—Least said, &c.

LABOUR SUPPLY.—Village labour chiefly, very irregular and unreliable.

TRANSPORT.—Two miles by coolies, thence river and canal.

ROADS.—Private path bad; public roads tolerable.

RICE AND SUPPLIES.—Prices very high; Ratnapna the dearest outstation in the lowcountry.

GRIEVANCES.—None that can be mended by a row.

ELPITIYA DISTRICT, (S. PROVINCE,) IN 1897.

WEATHER generally.—Very ordinary; rainfall consistent and satisfactory, although slightly below average.

CROP.—Slightly under estimates as a rule. Yet deficiency due more to overestimating than to natural causes.

LABOUR SUPPLY.—Sinhalese labour plentiful, and rates considerably higher than need be owing to reckless competition.

TRANSPORT.—Available at all times. Carts really to meet all demand.

ROADS.—In good order.

RICE AND OTHER SUPPLIES.—Supply always procurable although rates are high, nevertheless they compare fairly with quoted rates in newspapers.

GRIEVANCES.—None, but those that emanate from imagination and self-caused indifference.

REMARKS.—A happy valley that would be happier with more cordial co-operation for general good of proprietors.

MARAWILA DISTRICT (CHILAW) IN 1897.

WEATHER generally.—We had rain during every month of the year, with very heavy falls of 8 and 12 inches.

CROP.—Coconut and paddy crops have been good.

LABOUR SUPPLY.—Scarcity of Tamil labour all over the district. Sinhalese unreliable.

TRANSPORT.—The canal is the only means of through transport and on the whole it was in good navigable order except at Negombo, where it gets silted up with each rise of the Maha Oya.

ROADS.—There being very little heavy traffic on the main road, it was in good order. The old road was in fair order. Minor roads require attention.

RICE AND OTHER SUPPLIES.—Supplies sufficient, but prices very high and press heavily on the poor.

GRIEVANCES.—A more vigorous administration, viz., an A.G.A. untrammelled with judicial work.

REMARKS.—Badly served as regards mails. We have one mail either way and letters that reach Negombo one evening for districts northwards are forwarded the following noon! Two coaches leave Negombo together at noon and two leave Chilaw in the mornings. We want a mail for Negombo in the mornings, and from Chilaw in the afternoon. Our greatest want is a light line passenger railway.

BATTICALOA DISTRICT IN 1897.

WEATHER generally abnormal: too wet during the early and middle of year; too dry at the beginning of N.E. monsoon; too wet now.

CROP.—Under the average.

LABOUR SUPPLY.—As usual.

TRANSPORT.—As usual.

ROADS.—In fair order.

RICE AND OTHER SUPPLIES.—Prices very high.

GRIEVANCES.—Continual change of magistrate and D. J. Want of communication with outer world.

REMARKS.—When the railway has been extended to Batticaloa, and the old Dutch Bar is re-opened, this place will be only second to Colombo in importance. It is destined to be the great rice-producing district of the island, and it only wants facility of communication by land and sea to develop it. Coconut cultivation has been largely extended during the past year. The trees do not yield so much and do not last so long, as in the wetter portions of the island, but they make up for this by producing better nuts. What the district wants more than anything else is fresh blood and competition, and this it will not get, until it is easier to get in and to get out of it.

RANGALA—MEDAMAHANUWARA AND NITRE CAVE DISTRICTS IN 1897.

WEATHER.—The weather throughout the year was very favourable, no long spells of either rain or drought. Both the South-West and North-East monsoons were mild. The rainfall varied on different estates from 98 to 150 inches.

CROPS.—Tea and cardamoms were above the average, especially the latter, which has been a record year.

LABOUR.—With no great shortage we could have given employment to a few hundred extra hands. Sinhalese labour comes as a great help in pruning and all odd jobs. The arrivals from the Coast on his side have been few.

TRANSPORT.—The majority of estates have a coolie and tavalam transport to cart road of from 3 to 7 miles. Coolies dislike the work and will not stay where the work is heavy.

ROADS.—Our cart roads have been kept in fairly good order, but more might be done in putting down a larger quantity of metal and not cribbing it from the sides of the roads. The beginning of the year saw our roads all smashed up by the great rainfall in the latter part of December 1896. We badly want a few short extensions to make transport easy.

RICE.—We were kept well supplied, but the price was very high and likewise all Ramaeamy's curry stuffs &c.

GRIEVANCES.—We have one great grievance. Our Grant-in-aid cart road from Nugalenna to Kobonelle is to cost us 3/4th of the total expenditure; Government only paying 1/4th. We cut the road and at the last moment Government refused the half of the cost, and now charge us one-half the expenditure for laying down the metal and finishing it.

REMARKS.—Coolies were fairly healthy and are taking kindly to hospital, some of them are even anxious to go to it. The birth and death rate was normal. Factories were enlarged on a good many estates; a large new one built on Deanstone; and wire shoots are coming into favour. The tendency was to pluck finer all through the year. Very little new land was opened for tea; but longing eyes were cast on every available acre for cardamoms; we are beginning to find that cardamoms are more permanent than we at first thought and there is no doubt we will take to manuring them before long and also replant old fields.

MADULKELLE IN 1897.

WEATHER.—Very favourable for the first six months but quite the reverse for the latter half of the year; a fairly fine June being followed by three almost sunless months, with low temperature on the higher estates and consequent check to vegetation generally. Almost all estates have made less tea than in 1896, some very much less, and those which close their accounts to the 30th June, will have to reduce their estimates considerably.

LABOUR.—Plentiful on one or two estates, but most people would be glad of more coolies.

TRANSPORT.—Almost all estates employ their own carts or contract for the regular hire of the carts they require.

THE ROAD gets worse every year, for the simple reason that sufficient money is not spent on its maintenance and that the work done is badly done. The form of the road is to a great extent lost, and in heavy rains, where there is a steep incline which is pretty general above the 7th mile stone. The water runs down the road instead of into the side drains, ploughing out deep ruts and washing away metal and "blinding" together. These ruts are roughly filled up with metal, to be washed out again with the next rains. The road above Panwila was thoroughly well made originally by the old pioneer corps (though the trace is bad) being, like the magnificent road from Ratnapura to Badulla, all firmly paved with large flat stones below the metal. Had it not been so, it would have been cut through long ago. I mention this as Sir J. Grintlin's remarks in Council seemed to imply that work was better done now than formerly; quite a mistake.

RICE has of course been dear and a heavy loss has fallen on most estates, it having been issued to coolies at rates ranging from R4 to R4-40 per bushel. There was some scarcity at the time of the railway slip and some estates had to send their men to Wattagama and Matale in October.

EAST HAPUTALE IN 1897.

WEATHER.—The rainfall has been over 100 inches, rather more than the average and too evenly distributed for coffee, but very suitable for tea.

CROPS.—Coffee a vanishing quantity; tea a good average.

LABOUR.—Plentiful on most estates.

TRANSPORT.—Cost of transport has shown a tendency to rise during the year.

ROADS.—Minor roads in fair order. The Amptiyakanda Gap Road is to be re-surveyed and will then if all goes well be constructed from Randarawela to Leangawela factory.

The effects of the slip have not perhaps been felt so much here as in some other districts as we have alternative routes of supply by Hambantota and Ratnapura.

REMARKS.—Estimate for Haputale for 1898, 4,000,000 lb. from 10,000 acres in bearing.

KANDAPOLLA DISTRICT IN 1897.

We have had about an average rainfall; the S.-W. monsoon was mild, and we did not have as heavy wind as usual. It has been a good year for tea crop; and coffee what there is of it, has done well.

LABOUR seems settled and has been fairly abundant. The tramway from Nuwara Eliya is the great want of the district.

UPPER HEWAHETTA DISTRICT IN 1897.

WEATHER.—Generally favourable.

CROP.—Above the average.

LABOUR SUPPLY.—Sufficient except during the very busy months.

TRANSPORT.—Is also as usual except since October, when higher rates have been sought owing to the increased cost of food stuffs due to the rock-slip on the line.

ROADS.—The Government road from Ricketlegasgoda to Kandy 20 miles, is in bad order, and has been so for the past two seasons. Too much metalling is taken in hand at one time, which as the road is of a very steep gradient over more than half its length, makes it hard on the cart cattle, and the complaints of the drivers are just.

RICE AND OTHER SUPPLIES.—All ample.

GRIEVANCES.—Delay in delivery of postal letters, the runners taking 12 hours and more in covering 23 miles, Kandy to Hewahetta via Deltotta, whereas an allowance of 7 hours, even, would be ample.

MADULSIMA IN 1897.

WEATHER.—The past year has been rather exceptional in the abundant supply of moisture during our usually dry months, and also in the long-deferred arrival of the N.-E. monsoon, which really only set in properly at the beginning of December. Since then the rain has been almost incessant, nothing very heavy, but more continuous than I ever remember.

TEA has flushed well and many places have exceeded their estimates mainly owing to the unusually forcing weather. Since July, prices generally speaking for our teas have been good, one or two estates as usual showing up well in the London sale lists.

LABOUR.—There does not seem to have been nearly so much trouble with labour as in previous years. Coolies and kanganies are, I think, beginning to realise that pleasant as may be the spending of that extra advance screwed out of their unwilling Dorai, yet the day of reckoning comes before long, and the more sensible among them realise that they gain nothing in the end by moving about from place to place increasing their debts with each change.

The extension of our CART ROAD is being pushed on and the energetic District Engineer Mr. Arnasaalem is deserving of great praise for the excellent work done.

Had it not been for the stupid advocacy of another trace by a resident in the district, backed up by a late Government Agent who never took the trouble to examine the trace on which the road is now being cut, this extension would probably have been taken in hand several years ago. The main sufferers are the estates in Hewa Eliya, who now transport their teas to Lunugala, at a cost of 1½ cts. per lb. for the eight miles journey. Such is the unfortunate result of one man endeavouring to impose his will on the district.

WATTEGAMA DISTRICT IN 1897.

WEATHER.—Rainfall 14 inches over average; November and December very hot.

CROPS.—Generally good all round. December rather short.

LABOUR SUPPLY.—Ample generally.

TRANSPORT.—Rates nearly doubled in some cases owing to state of roads; severely tested by heavy plumps in December.

RICE AND OTHER SUPPLIES.—Cost influenced by slip on incline.

GRIEVANCES.—More work wanted on roads and more labour to do that work.

REMARKS.—An enterprising firm (like say Boustead & Co.) is wanted to start Motor Cars for transport on some of the awful roads now common in Ceylon, with central electric power station, at the big waterfalls in the districts.

LOWER DIMBULA IN 1897.

WEATHER.—Has not on the whole been very favourable for growth; especially was this the case during July, August, September and the beginning of October. Tea pruned during these months took very long to come into bearing again, perhaps longer than I ever noticed before. During November and the first half of December flush came on with a rush but unfortunately it shut up a good deal again from the effects of cold wet weather in the latter half of December.

CROP.—In proportion to acreage I do not think crop will be large; but I think the quality on the whole has been above average, notwithstanding the poor averages ruling.

LABOUR SUPPLY.—Rather scarce the first six months of the year, but fairly plentiful during the latter six months. The outturn seems to be poorest always during the busy months.

TRANSPORT.—An accommodation cart-road is badly wanted to the station at Kotagala from the North side; the only approach from that side being a narrow bridge path, with a large stream to cross and the bridge generally unsafe for a horse.

ROADS.—The condition of the roads has improved of late, but more roads are required, to shorten transport to station.

RICE AND OTHER SUPPLIES.—In spite of the slip there was no actual want of supplies, though the Chetties and bazaar-keepers tried to run famine prices. Prices and Railway rates have been very high.

GRIEVANCES.—Want of direct cart road to station from the North; a road could be got to station that would halve the distance and make an easier road. Platform and waiting-room accommodation at stations is inadequate.

GAMPOLA DISTRICT IN 1897.

A Happy New Year and a prosperous one to you all and all good wishes if not too late.

Reviewing the past year it must be admitted that it was one of the most anxious for all connected with the tea enterprise, since we began some 15 years ago, when we were all glad to listen to men such as Armstrong and Cameron and when we devoured with avidity everything they told us, old planters, about our new "Queen Tea." The year without doubt, has been a disappointing one to very many; but, after all it was more the rise in silver than any reduction in our average prices people felt.

WEATHER.—The weather generally has been all that could be wished; but the N.-E. plumps were not quite as heavy as usual. Taking it all through, the S.-W. was not a good planting one; but rains in the N.-E. enabled those who had planting and supplying to get both done in good time.

CROPS.—The estimates as a rule were pretty well secured though a few will be short. Prices both home and local have been miserable and those buying leaf and making tea for others had difficulty in making ends meet and in view of lower prices; the superintendent who sticks to his estate and keeps cost of lb. of tea as low as possible will command a decent billet. There are a great many men out of work just now—some 54 applications having been made lately for one vacancy and that a temporary one! Cost of leaf during the year was about 6½ cents per lb. and poor stuff it was. At our P. A. meeting on the 11th December, it was decided to reduce the cost of cash plucking to 1½ cent per lb. This is I think a fair rate to pay now and the Sinhalese

ave had a very fair time of it getting all along 2 cents per lb. Superintendents must be unanimous, however, and the agents should insist on the reduction as it makes fully 2 cents per lb. on cost of the lb. of tea.

LABOUR.—Coolies, both Tamils and Sinhalese, have been with few exceptions sufficient for requirements. The Chetties are having rather a rough time of it, as also the Caddy men, and Planters feel that these people have a lot to do with unsettling of Ramasamy and that they induce the kangany to ask their tundu and leave. If Government were to insist on a pretty big stamp being put on tundus, it would not only stop this much-abused system in a great measure, but it would be a very fair source of revenue, as most districts are swarming with them. Our worthy Police Magistrate continues to give satisfaction, but he is terribly overworked. The best thing for cooly, kangany and all concerned would be if we had a penal clause in our wretched Labour Ordinance, which would enable employers of labour, with debts of over R20 due the estate, to be in a position to refuse either notice or tundu while so in debt. This would at once not only raise Ramasamy from the dreadful state of doubt he is now in, but it would also be a direct blow at dishonest bolters and the rotten advance system, like a cancer gnawing out the very vitals of our planting enterprise. The Tamils have a most wholesome dread of being held in service for any specified term; so, I think, if being indebted to an estate or to his kangany over a certain amount held him if not in service, or limited him to the boundary of the estate till debt is paid; his condition, as also that of the planting employees, would be improved, for he would not be so fond of borrowing. Let him sever his contract of service by all means, but if indebted to the estate, or to his kangany over a certain amount, make his stepping over the boundary and finding new employment impossible until he has paid the utmost farthing. Other colonies have such laws for insolvent debtors (*white men*); why shouldn't we for coolies. If we had, our P.M. would have no work to do!

READS.—Mostly in very bad order and showing up the MacBride system in its true light. What a grand thing for the Colony a change of blood occasionally is.

HEALTH.—There has been a good deal of sickness during the year, but the average number of patients in our hospital has not been higher than usual. I never can make out what our Gampola Local Board is doing. The streets are a disgrace.

IMPORTATION OF SEED OF SHADE TREES INTO B.C. AFRICA.

We are authorised by the Commissioner to publish the following extracts from a letter from the Director of the Royal Gardens at Kew to the Foreign Office regarding the introduction of the seeds of shade trees into the B.C.A. Protectorate from India.

"The coffee disease was introduced into Fiji through the instrumentality of tea seeds from Ceylon. Notwithstanding the splendid attempts made by Sir William MacGregor to stamp it out, it ultimately completely destroyed the coffee industry, which was the most promising planting enterprise in the colony. The Germans by some unknown means have succeeded in introducing the disease into their African territories.

"In the face of these undoubted facts it would in my opinion be the height of folly to run the smallest risk of introducing the disease into British Central Africa where its presence would be an irreparable disaster.

"Knowing the mechanical way in which such work is carried out by native officials in India, I do not think that any stipulation as to locality is of the smallest value.

"Whatever was stated to the contrary, the first parcel of seed would in all probability come from a plantation reeking with disease.

"The present request is the more unnecessary as according to a coffee planter in Nyasaland who is

well acquainted with coffee cultivation in Ceylon, a local African tree '*Albizia fastigiata*' is admirably adapted for a shade tree for coffee. If this is no sufficient the rain tree or '*Platycodium Saman*' might be tried. The seed can be obtained in abundance from Jamaica and that would be perfectly safe.

"In view of the opinion of so high an authority as to the danger of introducing shade-tree seed from India H.M. Commissioner cannot consent to any infringement of the provisions of Clause I. of the Queen's Regulations for the prevention of Coffee disease in British Central Africa."—"B.C.A. Gazette," Nov. 7.

B. C. AFRICA: CURRENT CHAT.

A sale of 683 acres took place at Cholo a short time ago. The land is on or near to the Mowazi.

135 bags of Nyasaland coffee were sold in the last week of July at prices ranging from 58s. to 94s. 6d. The tone of the market at last advices was finer.

We are glad to hear that H. M. Commissioner has refused to allow any recruiting of labour for export from B.C.A. to take place. Captain Sewell leaves immediately, his errand having been so far fruitless. We hope he will meet with more success in districts where there is not the same need to conserve labour as here.

Mr. Selby of the A. T. T. Co., who was up in Central Angoniland recruiting labour, has returned to Blantyre. He was successful in obtaining some 300 labourers who are being sent on by the Administration.

Our veteran pioneer, Mr. J. W. Moir, who has just returned from furlough, has been spending a few days at Blantyre before going on to his estate at Mlanje.

The rains which fell at Blantyre on the 29th and 30th October have been of great benefit to the plantations there and a good spike has been brought out. They seem to have been very local however, as only slight showers are reported from Zomba and some parts of Cholo.—*Central African Times*, Oct. 1897.

PRICES OF COFFEE.

The *New York Journal of Commerce* says:—"Prices of Brazil coffees are now ruling at about the lowest figures in the history of the trade. In December, 1882, February delivery sold at 52½c. Since that date until the current year the range has been between 6½c. and 19c. During this year, however, there has been a gradual decline, and on the 9th instant November was quoted on the exchange at 44½@46c. W. H. Crossman & Brother, large receivers, and authorities on coffee matters, say:—"The decline is the result of a coffee production greater than the consumption. The quality of this crop in both Rio and Santos is the best that we have seen for twelve or fourteen years. The average is better than any crops, except the large ones of 1881-82 and 1882-83. It is proof positive that it is the product of young tree and not old trees. The quality of the old trees was so poor that during the year of 1893, 1894, 1895 and 1896 any coffee grading better than No. 7 commanded a heavy premium and resulted in the high differences made on the Coffee Exchange last year. The quality of this crop was certainly not expected by anybody. On the basis of the receipts up to date nobody can figure less than 5,250,000 to 5,500,000 bags Santos and 4,000,000 to 4,250,000 bags Rio. From two parties in Santos estimates have been received that the growing Santos crop is as large as 6,000,000 bags. In one case it was estimated that, including the new-crop coffee, which comes in during May and June, the receipts for the twelve months could not be figured at less than 6,000,000 bags. And while this is a very high figure, actual receipts so far argue strongly in its favor. The coming crop has been estimated as high as 6,000,000 bags for Santos and 4,000,000 bags for Rio. And for the present crop, as there are new trees and a large number that will bear fruit for the first time next year, it does not seem so unreasonable. It will certainly, I should say insure low prices for a long time to come."

CEYLON TEA IN AMERICA.

Our Tea Commissioner sends the Committee of Thirty a full and cheering budget of news which will be found given in our Correspondence column elsewhere. Mr. Mackenzie deals largely with the progress made in the Canadian Dominion and especially in Lower Canada through the enterprise of Messrs. Larkin & Co. in conjunction with Messrs. Tetley & Co.—both, we take it, receiving a subsidy from our Tea Fund in support of their work. But we are also told of progress in Boston, New York and Philadelphia, as well as in more inland towns—Cleveland and Entaloe—and still more in some of the Far West States. So, the good work of accustoming our American cousins to really good tea, goes on, and by-and-bye, Ceylon and Indian planters ought to reap the fruit by finding the consumption of machine-made teas across the Atlantic, double every year for some time. Mr. Mackenzie is very clear as to the advantage of the new Customs system—a number 26 sieve being substituted for a 16 sieve—and he gives Mr. Blechynden the fullest credit for the good work he performed in urging the Government until the amendment was granted. The result is that instead of pure Ceylon and Indian teas, inferior Japan and China teas are now being shut out in large quantities both from the States and Canada. These, the importers now propose, to ship to the London market—that refuge for the destitute and worthless. We have already mentioned how teas rejected at Melbourne as “unfit for human food” got reshipped to London where they sold to more than cover expenses. We trust the Ceylon-London Association may stir up the London Customs authorities to try and put a stop to this state of things, and a very good opportunity is presented now for catching, rejecting and destroying the inferior China's and Japan's about to be reshipped from America.

CEYLON TEA : WHOLESALE AND RETAIL.

Writing from the North of Scotland, Mr. A. H. Duncan raises a point that may be worth considering about our teas:—“I don't understand why your tea has gone down in price compared with that of India. There is no difference in the retail shops—Ceylon being still foremost—and the £12,000,000 which you speak of as being lost to Ceylon, must be going into the pockets of the men of Mincing Lane or the shopkeepers. I am paying the same price for the same quality of tea as I have done for the past three or four years, so the loss to Ceylon is not benefitting the tea drinkers of Britain.” We suppose the explanation is that our better high-grown teas have not fallen so much in price—but that our average has fallen chiefly through the effect of medium and low-grown teas being so largely produced

RAGALLA TEA ESTATES, LIMITED.

Report of the Directors to be submitted to the Shareholders at the Ordinary General meeting, to be held at 59, Lime Street, E.C., on Tuesday, 4th January, 1898, at 3 pm.

The Directors beg to submit their Report, and also Statement of Accounts duly audited, for the season ending 30th June last:—

Showing a nett Profit for the Season of.. £1495 6 5
And the balance of last Account .. 795 5 2

The Total is .. £2290 11 7

Out of which the following Dividends have been paid:—

1st January—Ordinary Shares.. £620 0 0
Preference Shares 609 16 6
1st July—Preference Shares 1050 0 0 2279 16 6

Leaving a Balance to carry forward of £10 15 1
During the year the crops realized in London were:—

Ragalla and Halgran Oya Estates, Tea, 205,858lb. at a gross average 9¹/₄d. per lb.

Kelburne Estate, Tea, 101,734lb. at a gross average of 8¹/₄d. per lb.

Ragalla and Halgran Oya Estates, Coffee, 341,090 cwt. at a gross average of 88s. 8d. per cwt.

Kelburne Estate, Coffee, 297,122 cwt. at a gross average of 98s. 6¹/₄d. per cwt.

The following are the acreages of the Company's Estates:—

	Ragalla.	Halgran	Kel-	Total.
	Oya.	burne.		
	Acres.	Acres.	Acres.	Acres.
Tea in bearing ..	615	11	463	1289
.. non-bearing ..	111	—	309	420
Coffee ..	—	—	10	10
Timber ..	150	15	135	300
Patna, &c. ..	123	166	64	353
Totals ..	999	392	981	2372

The estimates for the Estates for the current season are as follows:—

Tea Crop.—490,000 lb. at 8d per lb. nett ..	£ 16,331
Coffee Crop.—100 cwt. at 90s per cwt. nett..	450

Profits on Bazaars and Manufacture .. £16,783

Less Expenditure in Ceylon for upkeep ;
R169,564, at Exchange 1s 3¹/₄d .. £10,951

Gross Profit .. £6,212

During the past year a considerable amount has been spent on Capital Expenditure, which included the erection of the new and substantial Factory on Ragalla Estate, upon which was spent, to 30th June last, £5,376. The building was opened in June for the manufacture of the present season's crop, and has fully realized expectations.

The teas from Ragalla Estate are improved in manufacture and quality, and have in consequence sold at considerably enhanced prices, the average to date for the present season being for 48,210 lb., 1¹/₄d. per lb. nett, against an average for last season of 8d per lb. nett.

The crop for the present season, from Kelburne Estate, has averaged 7¹/₄d. nett for 20,020 lb., against 7d per lb. nett for last season. The earnings of the Company, in common with other undertakings of this kind, have been reduced by the unexpected advance in Exchange, the heavy loss caused by the dearness of rice owing to the famine in India, and also labour difficulties; but the Directors are glad to say that these latter drawbacks are now to some extent disappearing, but the question of Exchange is one upon which it is difficult to form a reliable opinion.

In addition to these adverse circumstances the crops, owing to unfavourable weather during the last two months of the season, resulted in a large deficiency as compared with the estimates.

The Directors, therefore, regret that they are unable to declare a Dividend on the Ordinary Shares.

There can be no doubt that the Company possesses a most valuable property, and the Directors do not hesitate to express their opinion that as far as they can foresee it cannot fail to be highly remunerative in the near future, as the benefit from Capital Expenditure which has been incurred for some years past in opening new land and in erecting the factory will show itself by increased crops and improved quality.

The crop for the past six months has sold considerably in excess of estimates, and prospects generally are more favourable for the ensuing year.

The Directors wish to express their satisfaction with the work done by the Staff in Ceylon.

Under Clause 97 of the Articles, Mr. C. Hannen retires from the Board, but being eligible offers himself for re-election.

The appointment of Auditors also rests with the Shareholders under the Articles of Association, and Messrs. Fuller & Wise, the present Auditors, offer themselves for re-election. C. STRACHAN,
Chairman.
24th December, 1897.

BOUND FOR TRAVANCORE.

Mr. and Mrs. Donald Reid, of Western Dolobage, leave before the end of the month to take up their residence in Travancore. Mr. Reid has been appointed to the management of the Hereford plantation, Shencotta, Travancore, belonging to the Messrs. Miller, which has very fine tea and large reserves. Mr. Reid—who is an experienced and much-esteemed Ceylon planter dating from the coffee days—will have a better climate in his new charge; but the country is primitive still in regard to roads. However, there is “a good time coming” for Southern Travancore; for when the long-expected Railway is made, it will pass close to Hereford estate. We congratulate Messrs Miller in getting so good and valuable a manager, and we trust Mr. and Mrs. Reid will prosper in their new home.

THE GAME PROTECTION SOCIETY OF CEYLON.

REPORT OF THE HON. SECRETARY.

PAST HISTORY.

The question of Game Protection in Ceylon has received considerable attention from prominent sportsmen and officers serving under Government for many years, and in 1888 a Committee, consisting of General Lennox and Messrs. Downall, F. C. Fisher, R. W. Ievers, and C. LeMesnrier, was appointed by the then Governor to consider and report upon the existing laws relating to the protection of game. It was recognized then that game was decreasing rapidly and that the laws were inoperative. Remedies were suggested, and amongst these an annual license on guns was recommended and a duty on guns locally manufactured.

Elephants and buffaloes received due attention, and it was proposed to raise the cost of licenses to kill or capture these animals, and a heavy export duty on hides and horns of deer and buffaloes was recommended. As a result of the deliberations of this Committee, Ordinances 10 and 11 of 1891 were passed by the Legislative Council, and, with the Ordinance No. 6 of 1893 and the Proclamation of 1894 prohibiting the export of hides of sambhur and spotted deer, were brought up to the Game Laws as they exist at the present time.

That these are somewhat defective and lamentably inoperative will, I think, be admitted by Government itself, and it is for the Game Protection Society to devise and propose some scheme whereby the condition of the wild beasts of the Ceylon forests may be ameliorated.

MR. T. FARR'S VIEWS.

To me it seems clear that until the active co-operation of the officers of the Forest and Survey Departments is secured, with the sanction and support of Government, the Game Laws will never serve the purpose for which they were framed.

A legislative enactment, such as the Madras Forest Act, combined with an Act giving special

powers to officers of the Crown, would, I am convinced, do much good and would be an immense boon to the Game Protection Society in the prosecution of its work.

I would urge in addition that the revenue derived by Government from the sale of game licenses and from fines inflicted on offenders against the Game Laws be either placed at the disposal of the Society or expended by Government in the protection of game.

My object in this paper is to furnish to members as full a report as space will permit of the work of the Society since its initiation in 1894; and upon perusal of the following pages it will, I hope, be admitted that we have not been idle.

WORK DONE.

Although no drastic measures have marked its progress nor radical changes in the Legislature borne witness to its power a beginning has been made which, with better and wider representation, will develop into a sound and powerful organization.

There are many difficulties to contend with in undertaking the protection of game in a country so varied in its natural features, where its forests extend for miles and miles beyond the every-day influence of the European, and where the unscrupulous native or Moorish trader can carry on his nefarious trade at the cost of thousands of lives undetected and unchecked. There are, too, when endeavouring to check the wanton destruction of the wild beasts of the forests, the interests of the different classes to be considered. The *bona fide* villager should be given a free hand in the matter of his food supply, and the cultivator should have no restrictions placed upon the due protection of his crops; but the law should be made far reaching in its scope and relentless in its administration when dealing with those who, for purposes of trade kill down hordes of deer which the most rabid of non-protectionists can never assert those created for that end.

MEETINGS HELD.

The following reports of meetings held and resolutions passed will speak for itself, and if Government has been inclined to turn a deaf ear to our recommendations and to leave us severely alone, we have not failed to endeavour to make ourselves heard.

On the 23rd May 1894, a meeting was held at the Bristol Hotel, Colombo, at which the following gentlemen were present:—

HE Rear-Admiral W R Kennedy (<i>presiding</i>).	
Captain Lyon, A.D.C.	Milo MacMahon, Esq.
Colin Murray, Esq.	H Glyn Eccles, Esq.
E Gordon Reeves, Esq.	T Y Wright, Esq.
A P Green, Esq.	Edmd Jeffries, Esq.
F H C Webster, Esq.	Hawtrey T Thwaites, Esq.
E H L Thomas, Esq.	W Waddon Martyn, Esq.
R V Webster, Esq.	Gerald Browne, Esq.
A H Thomas Esq.	E Rosling, Esq.
Richard Jackson, Esq.	Commander Fisher, R.N.
W Drummond Deane, Esq.	Lient. Hickley, R.N.
R W Ievers, Esq., C.C.S.	Lient. Hume, R.N.
Alex. Murray, Esq.	Lt-Col. Corse-Scott, R W
J E A Dick-Lauder, Esq.	Regiment.

The following resolutions were proposed and carried:—

1 That this Society be called the Game Protection Society of Ceylon.

2 That H. E. Admiral Kennedy be Honorary President and R. W. Ievers, Esq., C.C.S., President of the Society, and that E. Gordon Reeves, Esq., be Honorary Secretary.

3. That H.E. the GOVERNOR be asked to prohibit the export of Hides and Horns of spotted deer and Sambhur for at least 3 years, provided only that Government reserves to itself the right

of purchasing at the various Kachcheries (after due inquiry as to the *bona fides* of the vendors) horns and hides that are the property of genuine villagers. Also that some regulations as to the local tanning of hides be adopted by fee, licenses or other control. The outcome of this meeting was the prohibition of the export of hides of samblur and spotted deer for a period of 5 years as, from January 1st, 1895, by proclamation on Oct. 23rd H.E. Sir Arthur Havelock, K.C.M.G., Governor of Ceylon.

A second meeting was held in Colombo on August 14th, 1894, at which the following gentlemen were present:—

R W Ievers, Esq. (<i>president</i>)	C H Bagot, Esq.
T Farr, Esq.	H Wace, Esq.
H V Masefield, Esq.	W Saunders, Esq.
Edmd Jeffries, Esq.	E L Thomas, Esq.
Geo Beck, Esq.	J S M Ross, Esq.
W Murray, Menzies Esq.	A T Cathcart, Esq.
N Rowsell, Esq.	Fred Hadden, Esq.
H P Gallwey, Esq.	A H Pain, Esq.
F O Fisher, Esq.	Allanson, Bailey, Esq.
H Gordon, Esq.	A M White, Esq.
A Jackson, Esq.	H W Kennedy, Esq.
A Thomas, Esq.	G W Temple, Esq.
A M Hurst, Esq.	J V Owen, Esq.
A S Broun, Esq.	E Rosling, Esq.
R Jackson, Esq.	H E Power, Esq.
Ellian A King, Esq.	H Paterson, Esq.
A Tatham, Esq.	G A Craib, Esq.
B Ffashaw, Esq.	C M McCausland, Esq.
F H Price, Esq.	E Turner, Esq.
H M Philby, Esq.	F J Hadden, Esq.
	E G Reeves, <i>Hon. Secy.</i>

The following resolutions were proposed and carried:—

I. That a Committee be formed composed of all Government Agents and their assistants and all Conservators of Forests and their assistants and the following gentlemen, with power to add to their number:—

Geo. Beck, Esq.	H Pain.
H Gordon, Esq.	Major As, Esq.
A Jackson, Esq.	E Jeffrieby, Esq.
R Jackson, Esq.	H M Philden, Esq.
A T Cathcart, Esq.	F J Hadnts, Esq.
A M Hurst, Esq.	F L Clemeas, Esq.
C H Bagot, Esq.	M H Thomas, Esq.
T Farr, Esq.	A H Thomey, Esq.
E G Reeves, Esq.	H P Gallwey, Esq.
	W Bowden Smith, Esq.

To the above Committee the names of J. R. Barkley, Esq., and W. Hermon, were subsequently added.

II. That five shall form a quorum.

III. That the annual subscription be R5 for the current year.

IV. That the formulation of rules be left to the Committee.

As a result of this meeting the following rules were drawn out by the following members of Committee on August 17th, 1894.

R W Ievers, Esq.,	H P Gallwey, Esq.
Geo. Beck, Esq.	W Bowden Smith, Esq.
G M Fowler, Esq.	Major A H Pain
E Jeffries, Esq.	Frank Hadden, Esq.
A F Broun, Esq., C. G.	A M Hurst, Esq.
Forest Department	H Gordon, Esq.
A Tatham, Esq., C. G.	T Farr, Esq., <i>Acting Hon. Secretary</i>
Forest Department	
A H Thomas, Esq.	

Rules of the Game Protection Society of Ceylon:—

1 It shall be the duty of every member of the Society to make himself acquainted with the provisions of the existing Game Ordinances and to see that these provisions are carried out within his District.

2 It shall be the duty of every member of the Society to lay information as to a breach of

the Game Ordinances before a Police Court, and members may exercise their discretion as to whether they shall proceed directly against offenders or after reference to the Hon. Secretary.

3. In the event of an informant in a successful prosecution being a member of the Society, the reward received by him shall be paid into the Society's funds.

4. The Society shall receive through the Secretary applications from members for the appointment of paid watchers, these applications to be dealt with by Messrs. G. Beck and T. Farr in conjunction with the Secretary.

5. It shall be the duty of every member of the Committee to obtain for the Society as many members as possible.

6. Annual General Meeting shall be held on the dates of the Colombo and Nuwara Eliya Race Meetings at Colombo and Nuwara Eliya and an Extraordinary General Meeting shall be held in Kandy or elsewhere whenever called by the Secretary.

It was resolved at this meeting that copies of the Game Ordinances (interleaved) be supplied to each member of Committee for their information.

On the 2nd December, 1895, a Special General Meeting was called by the Hon. Secretary at Hatton, at which the following gentlemen were present:—

F L Clements, Esq. (<i>presiding</i>)	J Manley Power, Esq.
H Gordon Cuff, Esq.	W Maitland, Esq.
Capt. Justice	C Stafford Northcote, Esq.
J G Riadore, Esq.	H Blacklaw, Esq.
R Sidgwick, Esq.	D Renny.
W A Wilson, Esq.	E G Reeves, Esq.
T Farr, Esq.	Hon. Secretary.
K. H Plumridge, Esq.	

The following resolutions were proposed and carried:—

I. That Government be asked by the Society to allow a sub-Committee of sportsmen to make a draft of an Ordinance to revise the existing Game Ordinances in order to ensure the more efficient protection of game.

II. That Government be asked to provide a certain sum from the revenue collected from gun licenses for the payment of watchers for the protection of game, the Society finding an equal amount for the same purpose.

III. That the annual subscription due for 1895 be collected, and that the Hon. Secretary be asked to invite a certain number of members in each District to collect.

The Hon. Secretary, Mr. E. GORDON REEVES, resigned and Mr. T. FARR was elected in his place.]

Subsequent to the above meetings the Hon. Secretary approached Government on the subject of [the 1st and 2nd resolutions, and was informed that Government was not prepared to legislate further in this direction, and that the funds asked for could not be granted, as "it would be irregular to place public money at the disposal of a private Association in no way under Government control."

On February 18th, 1896, a General Meeting was held at the Hill Club, Nuwara Eliya, at which the following gentlemen were present:—

F. L. Clements, Esq. (<i>presiding</i>)	K. Macandrew, Esq.
Hon. W. Paulett	A. C. W. Clarke, Esq.
C. H. Bagot, Esq.	S. P. Gallwey, Esq.
A. W. Jackson, Esq.	F. J. Hadden, Esq.
R. Jackson, Esq.	H. M. Philby, Esq.
A. M. Walker, Esq.	W. L. Murray-Menzies, Esq.
W. Hermon, Esq.	T. Farr, Esq.— <i>Hon. Secretary.</i>
H. V. Bagot, Esq.	

The following resolutions were proposed and carried:—

I. That the HONORARY SECRETARY be requested to summarize the various suggestions made by members of the Society for the better protection of game in Ceylon and to forward the same to Government.

II. That copies of the Game Ordinances be purchased at the expense of the Society and distributed amongst the members.

III. That the Society regrets the indiscriminate manner in which licenses to kill game are issued to visitors to the island, affording privileges to them which far exceed those to local sportsmen.

This last resolution was proposed by a member who had been refused licenses to kill in a certain District more than one buffalo, when certain "titled" visitors had been granted licenses to kill three or more in the same District.

During this year the Honorary Secretary obtained from the Government Printer as many copies of the Game Ordinances printed in Tamil and Sinhalese as were available. These copies were distributed to members and were also sent to kangaries and coolies of certain estates where illegal destruction of game was being carried on.

On August 12th, 1896, a General-Meeting was held in Colombo at which the following gentlemen were present:—

R W Ievers, Esq., c.c.s.

(President)

F. C. Fisher, Esq., c.c.s.

Lient. A. C. Pitman, R.A.

A. M. Hurst, Esq.

W. S. R. Cox, Esq.

F. J. Saville, Esq.

W. L. Murray-Menzies, Esq.

Geo. Deane, Esq.

H. Whitham, Esq.

J. Wickwar, Esq.

C. H. Bagot, Esq.

H. O. Hoseason, Esq.

F. G. A. Lane, Esq.

H. Wace, Esq., c.c.s.

W. D. Bosanquet, Esq.

H. J. Vollar, Esq.

A. H. Thomas, Esq.,

T. Farr, Esq., Hon. Sec.

At this meeting the Honorary Secretary read his summary of numerous suggestions made by experienced sportsmen with regard to the better protection of game in Ceylon, which was as follows:—

Summary of suggestions received from a large number of sportsmen in Ceylon having in view the better protection of game in the Island.

ORDINANCE 10 OF 1891, Sec. 3.—Game should include Paddy Field Deer (*Axis Porcinus*.)

SEC. 5 SUB. SEC. 2.—License to capture Tusker should be R250 or R300.

If it is considered by Government that elephants require further protection, shooting at cow elephants should be forbidden.

SEC. 5 SUB. SEC. 5.—License to kill or capture game should be raised to R10 for each Province or R20 for the whole Island.

More stringent conditions and limits must be written on the backs of licenses by the Government Agents when issuing them.

CLOSE SEASON.—That a fixed period for the whole Island is inadvisable. That each Government Agent should ascertain from thoroughly experienced sportsmen in his Province or District the right and proper season that should be declared "closed," and should issue licenses accordingly. That gang hunting with beaters, dogs, and guns should be absolutely forbidden. Pitfalls, deadfall traps, large snares, spring guns and shooting game from machans should be made illegal. That sanctuaries should be declared by fixing limited areas of forest, from entering which all persons should be debarred.

That any person possessing fresh meat or raw hides or horns should be liable to account for

the same at any time, and that the Police or any Public Officer should have power to search for the same.

That the export of deer and sambhur horns should be prohibited for 5 years at least.

That guns should be licensed annually throughout the Island, the license to be obtainable at the local Post Office, and that in villages all guns should be handed in to the Kachcheri at the beginning of close season and restored at its termination to their respective owners.

That all Public Officers and a limited number of Members of Committee of the Game Protection Society should be empowered to demand the production of his license from any person carrying a gun, and to seize the latter and send it to the nearest Police Magistrate on no license being produced.

ORDINANCE NO. 10, 1891 SEC. 11 (d)—That a minimum penalty of R10 be imposed for every breach of this clause. After the words "capture game" should be inserted the words "or aid and abet in the same."

The Conservators and Assistant Conservators of forests should be empowered to investigate all cases where any infringement of Ordinances Nos. 10 and 11, 1891, and No. 6, 1893, has occurred, and to administer the law as laid down by those Ordinances.

That licenses to Immigrant labourers on estates should only be granted at the written request of the Superintendents of such estates. That the possession of live sambhur or deer should be an offence punishable by the law, as it is reported that a large trade is done in this manner.

Complaints against the visitations of the Globe Trotter are frequent and emphatic, and the general opinion amongst members of this Society is that the present facilities for sport afforded to visitors to the Island should be discouraged by considerably increasing the cost of a license to such strangers, and that local sportsmen should not be unfairly restricted in the matter of obtaining licenses.

A copy of the above suggestions was placed in the hands of H.E. the Governor who gave them his careful attention.

At this same meeting it was resolved that a Sub-Committee consisting of Messrs. R. W. Ievers, F. C. Fisher, C. H. Bagot and T. Farr should be authorized to expend immediately a sum of R500 on the importation of game, and on the 14th August, 1896 the Sub-Committee met to discuss the expenditure of this sum.

It was resolved that the following game birds be imported at an early date:—Black Francolin, Chukhor, and Hungarian Partridges.

The HON. SECRETARY was requested to make enquiries regarding the importation of the Indian Antelope (Black Buck) and Cervus Hippelephus (Mauritius Deer).

On March 1st, 1897, a General meeting was held at the Hill Club, Nuwara Eliya, at which the following gentlemen were present:—

Allanson Bailey, Esq., c.c.s. (Presiding).

Captain Marker, A.-D. C. F G A Lane, Esq.

E Boyd Moss, Esq., C G Forests C H Bagot, Esq.

W Ferguson, Esq., Alderson Smith, Esq.

North C Davidson, Esq., E Marker, Esq.

A E Wright, Esq., T C Huxley, Esq.

J Fraser, Esq., J Quayle, Esq.

R Jackson, Esq., J Wickwar, Esq.

T Farr, Esq.—Hon. Sec.

The following resolutions were proposed and carried:—

I. That Captain Ward Jackson, A.D.C., be warmly thanked for his liberality in presenting the Society with 21 chukhor, which birds he imported from N. India.

II. That it be suggested to Government that the export of deer and sambhur horns be prohibited, and that the prohibition of the export of the hides of these animals be continued indefinitely.

III. That the Game Protection Society, in reply to a minute from the Hon. the Colonial Secretary, sees no objection to the proposed Buffalo Kraal on the Ragalla Patanas, provided that no buffalo be shot in the Kraal unless absolutely necessary.

IV. That the Honorary Secretary be authorized to expend a further sum of R500 in importing chukhor, and to make enquiries the cost of importing other game birds.

V. That the Secretary be empowered to have printed and circulated, forms inviting membership.

A copy of the above resolutions was forwarded to the Hon. the Colonial Secretary, and on the 27th March, 1897, the following letter was received by the Honorary Secretary:—

Colonial Secretary's Office,
Colombo, March 26th, 1897.

Sir,—I am directed to acknowledge the receipt of your letter of March 12th forwarding for perusal copies of the resolutions passed by the Game Protection Society.—I am, sir your obedient servant,

J. J. THORBURN, for Colonial Secretary,

To T. FARR, Esq., Hon. Secretary, Game Protection Society.

ACCLIMATIZATION OF GAME.

From the minutes of the two last meetings it will be seen that the importation and acclimatization of game was first undertaken in 1826 under the auspices of the Game Protection Society, and late in the same year Hungarian and French partridges, 10 brace of each, were indented for by Mr. C. H. Bagot from Messrs. John Bailey & Co., London.

This experiment was attended with most disappointing results, and only twos Hungarian and two French partridges survived the long sea journey and reached Mr. Bagot alive.

These were turned down on the patanas adjoining St. Leonard's Estate in Udupussellawa, and represented an expenditure of £20.

Early in 1897 the Honorary Secretary received, through the kindness of Capt. R. Ward-Jackson, eighteen chukhor out of twenty-one birds that were despatched from Northern India.

They arrived in very poor condition, and three of them were evidently in a dying state on arrival. These were carefully nursed and attended to, but with no success.

The remaining 15 birds were confined in a warm and dry room with a "run" attached. With the exception of three sickly birds they appeared to thrive remarkably well on paddy and green food. Sods of turf were placed in the run twice a day and were soon made bare of vegetation by the birds who pecked at the blades of grass greedily. When considered sufficiently strong to feed for themselves, the surviving twelve birds were turned down on the Horton Plains in a sheltered and carefully chosen piece of jungle. They were fed three times a week for a short period, and water was supplied to them in small tins placed just on the edge of the forest. They had easy access to a stream of water some 50 yards from where they were turned down.

With the exception of a very small sum expended locally these chukhor cost the Society nothing.

THE RESULTS SO FAR.

The initiation and history of the Ceylon Game Protection Society having been given in the foregoing pages, a summary of the good done and points gained by it during the past three years may prove of interest to its members, and in order to set this forth clearly I must deal with each animal separately and summarize the reports of various sportsmen whose opportunities of forming a reliable opinion entitle them to respect and consideration.

ELEPHANTS.—These animals appear to have been on the increase of late years, and it is an undoubted fact that the enhanced license fee has checked their destruction in a most marked degree. It behoves the Society now to see that they are not destroyed for the purposes of trade by persons who may have discovered that their hides are of sufficient value to render the license fee of R100 a matter of no consideration.

BUFFALOES.—Reports reach me that a large and lucrative trade is carried on in dried meat and in hides, and that large numbers of buffaloes are killed by "Moormen" traders for these purposes.

SAMBHUR.—From my own observations in the Hills I am satisfied that there has been no decrease of late years; indeed, I am in a position to state that where legitimate hunting only has been the means employed to kill them they have increased in numbers.

Tracts of country too much overrun by estate coolies with guns and dogs or beaters have been almost denuded of game. Large numbers have been killed and still more have been driven to the quieter sanctuaries remote from cultivated land.

The more stringent conditions attached to licenses by the various Government Agents have proved beneficial, and during the past year many Tamil coolies were refused licenses altogether where they had in preceding seasons offended against the spirit of the game laws.

These measures have proved salutary, but I venture to question the propriety of issuing any licenses to kill deer to immigrant labourers on estates. In a force of, say, 200, to 1,000 coolies application will be made for 2 or 3 licenses at the most, but, protected by these, gangs of twenty and thirty go out into the forests and patanas and compass, jointly and severally, the destruction of many deer.

In the Plains I am told that sambhur are on the decrease, and that mature animals are seldom seen.

SPOTTED DEER OR CHITAL (AXIS MACULATA).—There is a general consensus of opinion that these beautiful animals are decreasing in numbers to an alarming extent. They are destroyed in the remoter districts of the Island in a variety of ways, even to the extent of herding them together during the dry season near water-holes and pools in dried up river beds and killing them with clubs.

Their hides are, I believe, the most valuable of all hides on the markets of Europe, and their horns as well as those of sambhur are exported in immense numbers.

RED DEER (OR MUNTJAC).—It is impossible to state with any degree of accuracy whether this timid little animal has benefitted by protection. That they are very plentiful in the habitats they most frequent is, I hear, an assured fact. They are

not slaughtered for their horns or for their hides, and as they breed and multiply more rapidly than their larger brethren, there can be no danger of their extinction or even decrease.

PADDY FIELD DEER (OR AXIS PORCINUS).—This handsome little beast inhabiting the jungles, mainly of the Southern and Western Provinces, has been inadvertently omitted from the list of protected game. He is by no means common, and being by nature more or less a day-feeder should receive the attention of all sportsmen in whose vicinity he may be found who should endeavour to extend to him the protection he merits and needs. For the information of those who may not have come across this deer $\frac{1}{2}$ describe him as a miniature sambhur.

PEAFOWL.—These birds are, I understand, becoming more and more scarce, as they are shot by native traders for their handsome plumage, and I fear their "closed" season is but lightly regarded by these poaching scoundrels.

MOUSE DEER AND HARE.—Theegis of protection is not extended to these animals which are very plentiful on the hills and plains alike, but sportsmen should endeavour to stop in their neighbourhood that pernicious habit of the Tamil cooly of setting dead-fall traps in the jungle and nets in the open patanas and scrub by which means large numbers are killed, whilst many a good hound and favourite dog has fallen a victim to the former.

HORNS AND HIDES.—The Proclamation of October 23rd, 1894, prohibiting the export of sambhur and deer hides compelled the traders in those commodities to seek fresh means of disposing of them, and a large local industry in converting them into leather is carried on in Colombo, as is evidenced by the large number of tanneries now in existence. Hides are also being stored in large quantities in anticipation of the expiry of the term during which the prohibition of the export is to be in force. The Proclamation should therefore be indefinitely prolonged.

I am of opinion that deer and sambhur hides are smuggled out of the Island in considerable quantities, concealed in cattle and buffalo hides as well as in native boats from South and East Coast Ports. A case of the former method was detected at the Custom House in Colombo some months ago, and the only punishment was, according to the newspapers, the confiscation of the hides.

With regard to horns of deer and sambhur, these are exported in sufficiently large quantities to prove that the export is not confined to shed horns. It is wellknown to all sportsmen who have studied the habits of deer that they eat the shed horns of their species very quickly, and unless the collector of horns goes his rounds very frequently he would find very little left for him to carry home. Within a few days all but the very base of the horn would be gnawed away and consumed.

Government is, I believe, to a certain extent in sympathy with the Society and would, I believe, gladly take measures to check the trade in horns could it be proved to their satisfaction that the bulk exported are not shed horns.

Horns stored for export in Colombo have been inspected and examined by members of the Society, and what would seem so easy to prove is by no means so. The itinerant Mahomedan traders who collect them have evidently some method of detaching them from the bone, so that

the horn has all the appearance of a shed horn, except that the corrugations on the base of the horn are rougher and fresher looking than they would be if shed in the course of nature.

On November 16th, 1897, the Honorary Secretary paid a surprise visit to one of the shops in the Pettah of Colombo where horns of deer are stored for export, and having discovered a large heap of deer and sambhur horns, took the opportunity of examining them closely with the object of ascertaining the proportion of shed horns amongst them. At a rough calculation not more than five per cent. were "shed" horns, the rest had bone attached and were undoubtedly those of killed animals. The Honorary Secretary was informed that the market value in London for spotted deer horns was R2 per lb., and that of sambhur horns 62 cents per lb. A pair of deer horns was then purchased for R5

It is believed by many members of the Society that the export of deer horns is not confined to the Port of Colombo, but that a large illicit export is carried on from the Southern and Eastern coasts. With this in view, the Hon Secretary on November 1st, wrote to the Hon. L. F. Lee, Principal Collector of Customs, asking for a statement of the export of deer and sambhur horns during the years 1896 and 1897 from Colombo and other ports, and the following reply was courteously and promptly returned:—

No. 1,113.

H. M. Customs,

Colombo, 3rd Nov. 1897.

SIR,—I have the honour to enclose a statement giving the information asked for in your letter of the 1st instant.

No horns were shipped from other ports in the Island during the period mentioned.

I am, &c.,

L. F. LEE,

Principal Collector.

THE EXPORT OF DEER AND SAMBHUR HORNS SINCE 1892 TO THE PRESENT DATE IS GIVEN BELOW IN HUNDREDDWEIGHTS.

	1892	1893	1894	1895	1896	*1897
Deer	..	—	—	—	548	512
Sambhur	..	—	—	—	605	295
Total	..	1313	1643	1760	1439	1153

* For the first 10 months.

The above figures represent a ghastly record of slaughter.

It has been stated by the Custom House authorities that the average number of Sambhur horns to a cwt. is 114, and of deer 130. This evidently refers to the single horn and not the pair, for they are all cut or sawn in two for shipment.

If members of the Society will now reckon up the value to the trading native gunner of a spotted deer, of its flesh, its horns and its hide he will find that the temptation to make a trade in their carcasses is very great. It should be borne in mind also that more hinds than stags are killed by natives.

I am unable in this report to give a list of prosecutions under the Game Ordinances, but they are comparatively insignificant and will be dealt with in my next Report.

I append a statement of the Society's funds and accounts to the present date.

THOS. FARR, Hon. Secy., G.P. Society.

THE HONORARY SECRETARY IN ACCOUNT WITH THE GAME PROTECTION SOCIETY.

PIANTING NOTES.

SILKWORM. — Our local lovers of sericulture will be interested in the following: — “An interesting experiment is being made by the Department of Revenue and Agriculture in the importation of a quantity of China silk cocoons (anthea pernyi). These have been procured from mountainous districts in China, and the cocoons are, therefore, being sent to Darjeeling and Chakrata.”

“PASSING OF THE OLD-SCHOOL GROCER.” — Under this heading an article signed “S. Elwood May, successor to the Ceylon Planters’ Tea Co.,” appears in the American “Merchants’ Review.” At the outset the author states that in his many travels in pursuit of new clients in the interest of the Ceylon planters and their bhud, tiffin and bungalow teas, his mind had been directed to how rapidly conditions change in that country. He states: —

Not many years ago, when I pioneered the introduction of Ceylon tea, the leading grocers of every city, large or small, were autocrats, who stoutly resisted any innovations of whatever nature, pleasantly dictated to their customers, and followed out their own ideas absolutely. This method of procedure caused me to study other lines of business, and I found that the grocer was the only old-school merchant successful at that period. Those representing other lines of trade had long ago been forced into transacting business in accordance with the advanced methods of the day. I made up my mind that the old-school type of grocer, wedded to his traditions and ruts would soon find that the prerequisites to future success would be the following out of his clients’ whims instead of his own. I recently travelled some six thousand miles, and in most of the cities that I visited the passing of “ye olden school” grocer was quite visible.

After relating incidents, he concludes: —
I am one of many who wish the old-time merchants yet remaining would change before it is too late, for whatever credit may be given to the new school ones, all honor to the integrity and lofty purposes on the whole that have always existed in the class of the olden school,

THE “INDIAN FORESTER,” edited by J. W. Oliver, Conservator of Forests and Director of the Forest School, Dehra Dun, for December 1897, has the following contents:—Original Articles and Translations—Nitrogen and Forest Crops by E. Henry, translated by G. F. Gleadow; Obituary—Mr. C. H. Hobart-Hampden; Correspondence—Extra Pensions for the Forest Department; Dry Rot in Deodar trees; Sir Richard Strachey and Indian Forestry, letter from A. C. Wild; The After-Training of Cooper’s Hill Men, letter from ‘Spificator’; Official Papers and Intelligence—The Destruction of the Prickly-pear with the aid of the cochineal insect and other parasites; Ceara Rubber in a Malabar District; Extracts, Notes and Queries; Timber and Produce Trade; and Extracts from Official Gazettes.

INDIAN TEA COMPANIES.—The Planters’ Store and Agency Company, Ltd., has issued an analysis of the working of several London Tea Companies. Three companies stand far in front of the rest in the dividends declared in 1896, namely, the Assam, the Brahmaputra Tea Co., and the Jorehaut Tea Co., all of which yielded dividends of 20 per cent. The Doom Dooma Tea Co., and Balijan Tea Co., come next with dividends of 12½ per cent. but as regards the profit per pound of tea, Balijan and Doom Dooma take priority with 49/16d and 4-3/32d. In the percentage of profits over the entire share and Debenture Capital the Assam and Brahmaputra Tea Companies take the lead 23-14 and 23-43 per cent.—*I. P. Gazette.*

CEYLON LAND AND PRODUCE COMPANY.—We omitted to mention that besides the 15 per cent of dividends for each of the past six years, the fortunate shareholders in this Company got in addition, in 1893 and each of the last three years a bonus of 5 per cent, making 20 in all. The following return issued with the annual Report of the Directors is of interest:—

THE CEYLON LAND AND PRODUCE COMPANY, LIMITED, STATISTICS FOR PAST EIGHT YEARS:—TEA;

Year ending 30th June.	Acres of tea in bearing	Crop, lb.	Average per acre, lb.	Teas made for others, and from purchased leaf, lb.	Net average per lb. realized for all tea sold in London.	Rate of Exchange.	Rupee, Centes.

OUR STAPLE EXPORTS FOR TEN YEARS
—AND DISTRIBUTION FOR 1896-97.
COCONUT PRODUCTS.

The growing importance of the Coconut industry, and the extraordinary change which has taken place in recent years in the distribution of the products of the Coconut palm, require a fuller consideration of the figures contained in the table of Exports we issued as a Supplement last Saturday, than they might otherwise receive. Although, in figures, the exports of the ripe nut in the shell and of the kernel after desiccation may make a braver show, it is the Oil which, after all, is the chief product and continues to govern the price of nuts. Estates in the immediate vicinity of Desiccating Mills may calculate on the new industry, which has sprung up within the last decade and which can show figures only for seven years, as controlling the market; but it is not in reality so; although such estates may benefit by their situation in saving transport and breakages, while commanding the same price for delivery at the Mills as Estates more distantly situated. And why Oil rules the market will appear at a glance, if we consider the exports only for last year. Whereas the number of Nuts exported was 13,610,588, and was exceeded only once in 1896, when about a quarter million more nuts were sent away; and whereas the record figure for Desiccated Coconut (12,054,452 lb.) represents, at three nuts to the lb., between 36 and 37 million nuts, the export of 409,600 cwt. of Oil represents no less than 204 million nuts, at 500 nuts to the cwt. Hence the importance of developing the Oil trade, and hence the significance of our inquiry into the causes of the vast difference in price between Cochin and Ceylon Oils. The upshot of our Circular appeal has been to place beyond doubt that the main factor in the advantage which Cochin Oil has in the Market, of between 30 and 40 per cent in the price, over ours, is the careless drying of local copra, which renders the extraction of white Oil from the greater part of the supply impossible. Mill owners do utilize the kernel from the drier districts which are able to avoid fire-drying and can turn out clean copra to manufacture a proportion of colourless Oil; but clean, white copra, so far as we can see, does not command the relatively higher price it should, chiefly because of the preponderance of bad copra. The general outturn of our Oil is slightly yellow; the price quoted is for Oil of that quality; that rules the price of copra; and it is the mill-owner who chiefly benefits by the white Oil he is able to extract from the white copra that comes into his hands, and not the owner of the copra who gets little beyond the market price for ordinary copra for his produce. The remedy would seem to lie in the general improvement of the quality of our copra, which would improve the general quality of our Oil, as it would hardly pay individual proprietors to manufacture and ship only their own white Oil. Or can it be expected that some capitalist may start a Mill only for the production of white Oil by purchasing only sun-dried clean copra?

But to return to the figures—the export of Oil last year was only a fair average quantity. It was in excess of the figures for the two previous years, but it fell short of 1894 when 487,571 cwt. were exported, and far short of 1892 when the figures reached £50,977 cwt. We cannot, therefore, record a progressive development of the Oil trade; but it is important to note that the

fluctuations in exports are in no way connected, as is the case with upcountry products like tea, coffee, cocoa &c., with seasons and crops. The exports of most of our staples represent practically the total production of the island for the year; the out-turn of Oil depends, not so much on the crop of nuts, as on the price of Oil and on the demand for it. Had prices been higher and the demand stronger, we take it that we should have been able to send away quite as much as in 1892, with perhaps a slight reduction in one or more of the other forms in which the products of the palm are exported. In such case, the brisker demand for Oil would have led to higher prices for copra and for nuts. And that leads us to a consideration of the distribution of Oil during the last two years in which there has been little short of a revolution. Ever since Coconut Oil formed one of our staple exports, the United Kingdom has been its largest purchaser, and the leaves from an old mercantile book of 60 years ago, which we recently published, disclosed almost the beginning of the trade; but last year the United Kingdom took only 72,004 cwt., out of the total of 409,600 we exported. That is only about one-sixth of our total exports, and nearly 20,000 cwt. less than was taken in 1896, which itself showed a considerable falling-off. Nor are there larger shipments for Continental ports to suggest the supersession of the London market by direct importations. Austria's imports of our Oil fell from 24,313 cwt. to 8,717; Belgium's from 3,314 to 1,133; Germany's from 17,141 to 5,754; Italy's from 1,317 to 310; while France and Russia which used to take a few hundred tons, have disappeared as customers! This falling-off in custom was not due to prices which, if any thing, showed a slightly downward tendency. The cause was probably cheap tallow which was reported to be very abundant in America and the United Kingdom. It would be interesting to inquire whether the quality of our Oil told against it, and whether the countries which took less from us, took more from Cochin, or found other substitutes. It is not unlikely that in some cases, and to some extent, larger importations of nuts and copra compensated for the falling-off in orders for oil. Anyway, what we wish to point out is the great shifting there has been in trade whereby India almost doubled its demands on us, and took away 166,238 cwt., against 86,796 the previous year. She is thus far and away our best customer, taking from us more than twice the quantity which the United Kingdom imported, and almost twice the quantity which America our second best customer indented for namely 88,009 cwt. Here, too, we find, if not a revolution, a considerable change, as it is comparatively recently that America began taking our Oil. She soon proved a good customer, but was long far behind, although now she is ahead of, the United Kingdom! Another place which has almost doubled its demand is Singapore which took 64,058 cwt this year against 34,133 in 1896. The great free Port of the Straits and India have thus taken from us considerably more than one-half of our total output of Oil; and if our older customers revert to their large orders, the brisker demand should lead to higher prices. But how is this to be secured? Cannot coconut growers combine to act in the way tea planters have combined, to make their teas known in new markets, and to study the requirements of the old markets?

The effort is worth making, if there could be a satisfactory organisation, because, as we have seen it is the demand for Oil that governs the price of nuts; and with large extensions and immense areas coming into bearing, the supply may possibly go ahead of the demand.

In Copra, too, the exports represent only a fair average quantity in 106,601 cwt., though that is double the quantity sent away in 1896. Germany took 42,878 of the total output and Belgium 25,245 cwt. In Desiccated Coconut, the progressive increase has continued—12 million lb. having been sent away against 10½ million in 1896; but we are not hopeful there will be much more expansion in the manufacture. Already, we learn that some of the smaller Mills have restricted their output, or ceased work for some months of the year. The article is not one that improves by keeping; and although the oldest establishments may be able, through good business connections and advance orders, to keep up their output or increase it, there is no encouragement for new factories. More than three-fourths of the exports have been to the United Kingdom. America follows with 960,917 lb. or less than one-tenth of the total quantity; Australia with 672,897 lb. and Germany with 542,963 lb. Reference to other lowcountry and native products we must reserve for another occasion.

THE CEYLON TEA CORPORATION, LIMITED.

An extraordinary general meeting of shareholders in the Tea Corporation, Limited, was held on Wednesday (Dec. 22nd) at the registered offices of the Company, No. 15, Bishopsgate-street Within, the chair being occupied by Mr. H. W. Tagwell.

The SECRETARY (Mr. Alfred Howell) read the notice convening the meeting.

The CHAIRMAN said: This, as you know, is only an extraordinary general meeting of the Corporation, and therefore the business we have to transact is purely formal. I will, however, give you a brief account of the Company's property, taken from the reports of our managing director in Ceylon. Mr. Tatham's reports are satisfactory. He left London for Ceylon at the end of July; but owing to delay in transferring the estates, he is just taking over the actual management of our properties. In the meantime he has been visiting all the estates and advising the managers how to proceed, and under the circumstances they are naturally ready to value his advice. In the estimates in the prospectus we put the yield of Dotaloya and Penylan at 530,000 lb. of made tea. I may remind you that these two estates produce nearly one-half of our tea. Now, our manager states that he will be rather disappointed if they do not produce 550,000 lb. during the first year of his management, and that in the third year he hopes to work the yield up to 700,000 lb., or an increase of 170,000 lb. of made tea. You must add to this the increase on the Kudaoya group which he is sure he can effect. The average net price so far obtained for our teas has been very satisfactory; but against this has to be set the advance of exchange and the high price of rice owing to the Indian famine. Our managing director, in his report on Dotaloya, says: "The factory is a fine building, and capable of making 500,000 lb. of made tea. The estate, taken acre for acre, would more than hold its own against any estate in the island. In the past it has suffered from scarcity of coolie labour, but in recent months the labour force has been increased by 481 men, with 200 more coming in." He also says he sees no reason why Dotaloya should not give 400,000 lb. in 1900, if the estate is aided with a little manure. Penylan is smaller than Dotaloya, and yet produces 250,000 lb. of made tea, which should be increased to 300,000 lb. In Penylan a gradual improvement can still be made. I think, therefore, we may

congratulate ourselves on being the owners of a good and improving property, which in my judgment, should soon show very good results. (Applause.)

The CHAIRMAN then moved certain special resolutions embodying some changes in the articles of Association so as to comply with the requirements of the London Stock Exchange.

Mr. SMITH seconded the resolutions, which were carried unanimously.

A desultory discussion ensued, during which Sir Charles Lawson asked how long it would be before any return of the tea would be made.

Mr. HANCOCK replied that for the first half-year the tea would not be sold until an interval of something like another three months had elapsed, so that it was impossible at present to answer that question.

A SHAREHOLDER asked whether it was the intention of the Board to declare an interim dividend.

The CHAIRMAN said he considered that the shareholders should give the directors a little time to see how things went.

A SHAREHOLDER said he considered that these matters might very safely be left to the discretion of the directors. (Hear, hear.) He had visited most of the estates in Ceylon belonging to the Company, and could confirm everything that the Manager had said in regard to them. The production on the estates had in the past been limited by the difficulty of obtaining a sufficiency of coolie labour; but the manager had now a force of 400 extra coolies coming on the plantations, and he had no doubt that the product in the future would be very largely increased.

Mr. SHAND also spoke hopefully as to the Company's prospects, and said that if reasonable arrangements could be made in regard to freight the estates would no doubt do very well.

The CHAIRMAN, in acknowledging a vote of thanks which was unanimously passed to the board of directors, expressed a hope that at the next meeting they would be able to put the shareholders into possession of an even more favourable statement as to the Company's position.

The proceedings then terminated.—*Grocers' Journal*, Dec. 25.

PROPOSED ASIATIC COMMERCIAL MUSEUM AT SAN FRANCISCO.

The United States Consul at Bangkok proposed, in a report to his Government, the establishment of an Asiatic commercial museum at San Francisco on similar lines to those of the Philadelphia Museum, for the special purpose of bringing the immense markets of the Asian Pacific into closer touch with those of the United States, and providing manufacturers and exporters with ready and accessible means for securing all kinds of information relative to the markets of the Far East. He recommends, *inter alia*, that the exhibits should be samples which could be readily obtained and shipped to the museum at San Francisco, or, if too cumbersome, then photographs could be made, the main object being to show exactly what competition must be met in style and quality. A study of these, with information as to prices, would provide the exporter with sufficient details and enable him to determine whether he could enter the field or not. It now requires fully three months for a manufacturer to receive a reply to enquiries sent to Asiatic ports, but through a museum of this kind the same information could be obtained in ten to twelve days, whilst exporters would reap the benefit of frequent consultation and ready access. The exhibits should consist of exports as well as imports, and all necessary information as to prices, firms, duties, etc., should be provided.—*Imperial Institute Journal*.

CEYLON LAND AND PRODUCE COMPANY, LIMITED.

GENERAL MEETING.

The thirteenth annual general meeting of the Ceylon Land and Produce Company, Limited, was held at 101, Leadenhall Street, London, E. C., on Wednesday, the 22nd December.

The chair was taken by Mr. William Keiller.

The Secretary having read the notice convening the meeting,

THE CHAIRMAN'S SPEECH.

The Chairman said: Before passing to the report I wish to remark that Mr. Wilson has expressed his regret at being unable to be present at this meeting, but he considers the company's interests will be better served by his remaining in Ceylon for a little while longer. Gentlemen,—The report of the directors for the year ending June 30, 1897, is in your hands, and I presume it may be taken as read. The statistics issued with the report, covering the crops of tea and cacao for the past eight years are so complete that I have nothing further to add in this respect. With regard to coffee, I am sorry to say that the crop was a very small one: in fact it was too small (only 264 bushels) to deal with in the same way as we have dealt with tea and cacao. I may say that the tea crop exceeded the estimates by 62,000 lb., but realised in Ceylon currency about five cents per lb. less than the previous year. Cacao fell short of the estimates by 50 cwt.

NO CACAO DISEASE.

This deficiency occurred solely in the North Matale group, and was due to abnormal rains in December last which injured the blossom, and, roughly speaking, resulted in a diminution of the crop by 200 cwt. With regard to cacao disease I may give you the opinions of the superintendent and Mr. Wilson regarding our estates. The former states that a tree here and there may have died (the same as happens to coffee, tea, or any other product), but no patches have died out and that there is no more disease now than what might have been, say ten years ago. He has made a point of going carefully through all the company's clearings, but has not seen a single instance of the disease that is being written about just now. He has questioned all the superintendents, and likewise the kanganyies, if they have seen any signs of it, but their verdict is in the negative. He hoped this state of affairs may long continue. He has been over estates where it does exist, but he says it is nothing so serious as he was prepared to see. Most of the company's cacao is on undulating and pretty steep ground, which is a great advantage, I understand, although it may not crop so freely as what is planted on flat land. Trees die out here and there from different causes, as they have done ever since the company's cacao was planted, but to no greater extent than previously, just as tea does, and fruit trees and bushes in England. Mr. Wilson reports he has never seen the company's cacao, with the exception of some backward patches of the new clearings, look better than at present, and I think you will agree with me that this is a very satisfactory state of affairs for this company.

VARIOUS PRODUCTS.

At the last meeting the directors were asked to obtain a census of coconuts, and I now give you the figures collated in September last: 1,343 trees in full bearing, 16,052 trees not bearing (these all promise well), 24,336 nuts in nurseries. I will now direct your attention to our new clearings. Our last reports from the Alloo-wharie group state that they are doing well, and promise to be successful. As an indication of the progress being made here, I may say that during last year 8,000 lb. tea leaf were secured, whilst the estimate for the current year is 30,000 lb. leaf. We have seven acres of tea four and five years old in bearing, and in addition are now plucking from a portion of a 40-acre lot. About 20 acres have been added to this estate by purchase. The tea clearings at Andangodde are coming on very well; they consist of 6½ acres under three years old, 39½ acres above one-year old. The 80-acre clearing on Fetteresso is making good progress—we hope to commence plucking off about 30 acres during

the coming calendar year, and the balance in the financial period 1898-99. The young cacao at New Peradeniya is doing well, and at the moment there are no signs of disease whatever. The tea clearing also is progressing favourably, and in time will be a good field. During the present year the plucking area will be increased by nearly 30 acres. The coffee clearings at North Matale have not done well, I am sorry to say, the Arabian variety being almost a failure. It had a bad attack of leaf disease shortly after being planted, and since then it has not fully got over it. The young tea and cacao make good progress; sixteen acres of tea will come into bearing next financial year, and fifty-five acres of cacao in 1899-1900. The area of Owella has been increased from 261 to 372 acres (by purchase), whilst the planted area now comprises 165 acres of tea, cacao, and coconuts. On October 31st the superintendent reports that the general condition of the estate is improving, and the various products are doing well and have a healthy look. The figures given in the directors' report for 1895-96 with regard to Strathisla, were not quite accurate owing to an error on the part of the superintendent, but I think the acreage statement, which shows an increased area of about sixteen acres in the present report, is substantially correct.

TO SUM UP.

The high opinion previously formed by Mr. Wilson of this estate he still adheres to. He thinks that in course of time we shall have a very valuable asset. It now remains for me to sum up. In 1896-97 we had 1,571 acres of tea in bearing, and thus it will be seen that our total tea clearings amount to 660 acres (including coconuts on Owella), all of which will come into bearing during the next few years. The bearing area of cacao last year was 929 acres whilst since 1893-94 we have planted 445 acres, which will, we hope come gradually into bearing from 1899-1900 onwards. Now as to the prospects for the coming year. The estimates provide for 752,500 lb tea, against an intake of 749,000 lb last year, and a cacao crop of 2,500 cwt, comparing with 2,266 cwt brought into store during the past twelve months. Including tea made for others and from purchased leaf of our total estimate of tea figures out at 1,107,000. My advices from Ceylon bring estate figures down to November 15th, and at that time we were 23,000 lb tea ahead as compared with the same date last year, the increases being mainly from New Peradeniya and North Matale. Fetteresso and Rickarton crops are, so far, short, owing to the very wet weather encountered. On the whole, I think the prospects of our estimates being exceeded are encouraging. The cacao intake to 15th ult. is 375 cwt, and compares well with 141 cwt secured by November 15th, 1896, but it must be borne in mind that the crop is earlier this year than last. It is, of course, too soon to make any prophecies about the total cacao crop, but if I may hazard an opinion, I think it is likely—given normal weather—that the estimate will be secured. I now turn to the profit and loss account and balance-sheet, and with your permission will deal with the items seriatim. Upon comparing the present profit and loss account with the previous one, it will be seen that expenditure on crop account has been increased by £2,248; this is due to rise in exchange from 1s 2d to 1s 3d loss on rice, and cost of handling the increased tea crop.

THE RISE IN EXCHANGE.

The rise of a penny in exchange has cost us over the entire expenditure a little more than £1,800. Interest on debentures and loans is a decreasing quantity, the aggregate of bonds outstanding and the rate of interest payable being reduced. On the credit side it will be found that produce has realised rather more than £750, as compared with last year. Commission show a reduction from £753 to £190, whilst we have made a profit in realising the produce outstanding from the previous year of £177. Turning now to the balance sheet, it will be found that our paid up capital has been increased by £3,200, being the proceeds of a 10s. call on the ordinary shares. Debentures have been paid off to the extent of £5,140,

Deposits are much the same. Sundry creditors, consisting for the most part of advances against produce, indicates a reduction of £536. The large increase in bills payable is due to a larger expenditure and also to the fact that an acceptance for a substantial figure matured in the early days of July. On the other side of the account our estates show a book value of £103,082, or an increase of £4,095. This represents the sum spent upon purchase of land, opening, and planting, plus up-keep of our new clearings during the year. The three following items need no comment. Coast advances are an increasing item, due principally to two causes: (1) the rate of advances has a tendency to grow; (2) we need a larger number of coolies in connection with the new clearing. It will be of interest to point out that we have 1,374 acres of cacao and 2,232 acres of tea, and that, allowing £5 per acre for forest, chena, &c. (say 1,550 acres), adding £2,000 as capital expenditure from July 1st to date, and deducting the reserve fund, the planted area of tea and cacao stands in the company's book at £24 12s. 5d. per acre.

The report and accounts having been adopted, and the dividend and bonus declared, Mr. William Kciller was re-elected a director and Mr. James B. Laurie an auditor.

The usual vote of thanks to the chair was carried unanimously.

NORTHERN QUEENSLAND AND THE "TROPICAL AGRICULTURIST."

A Queensland planter, ordering the T.A., writes from Geraldton, Johnstone River, Northern Queensland, on 10th Dec. and says:—

"I have read the numbers received with great interest. Such a paper is just what we require in Northern Queensland, and more particularly the articles relating to coffee and rubber growing. The first-mentioned is likely to be largely planted both in this district and Cairns, the climate and soil being well adapted for its growth. It may interest you to know that the price received by the Cairns growers this season was 9d per lb."

Ninepence a lb. equals 84s a cwt.; a very good price for coffee not very well-prepared probably, in view of the absence of pulpers and proper factory arrangements? These will come in time. Climate and soil are evidently well adapted for coffee in Northern Queensland.

PLANTING NOTES.

MATALE AS A TEA DISTRICT.—Matale has—says a contemporary,—not generally been considered a leading tea district, nor has it attracted much attention by its big yields or high prices. Probably its failure as a coffee district towards the end of the coffee era, and the disappointment experienced with cacao by many proprietors, prejudiced planters against it, but Mr. Storey (see our 6th page) again shows that Mariawatte is not the only estate that can boast of continuous big yields. It is true that the record for Warakamura does not cover such a series of years as that of Mariawatte, and the total acreage is not so large, but on the other hand the outturn of the 204 acres, which was 993 lb. in 1896 and 1,066 lb. of made tea in 1897, is higher than the yield of the 458 acres of Mariawatte, but does not beat the old 100 acres field of the Gampola estate, though Mr. Storey says his yield has been obtained without the aid of manure. If the yield goes on increasing, we may soon expect Warakamura to equal the record yield of the Mariawatte old field, and over twice as large an acreage. We shall look for future returns with interest, and we are glad to hear that there are other estates in Matale doing nearly as well.

COFFEE.—At a meeting of the Coffee Trade on Wednesday to consider the advisability of altering the conditions of public sale with regard to small lots, it was decided that no alteration from existing rules should be made.—*Grocers' Journal*, Dec. 25.

"HAND-BOOKS OF COMMERCIAL PRODUCTS."—We have to acknowledge receipt of No. 10, on Adhatoda Vasica. Revised by David Hooper, F. I. C., F. C. S., Assistant Curator, Economic and Art Section, Indian Museum.

FRUIT AND THE VINE.—There are now in Victoria 36,023 acres under fruit—an Australian exchange tells us. The wine-growers are becoming fewer, and have fallen off to the number of 372 during the last year. The area under vines is 28,000 acres. Tobacco-growing is another industry which shows a great falling-off from former efforts in that direction.

A FIREPROOF TREE.—A Government report from Colombia describes a tree, known as the Chaparro, which is said to be fireproof. It grows on the immense plains of Colombia and the north of South America, and when the enormous fires set going to clear off rank vegetation after the rainy season strip the surface, the bark of the Chaparro protects it, and it grows on unscathed.—*Sydney Mail*.

CINCHONA BARK.—Louis XIV. for his "great Encouragement for Useful Discoveries of all kinds and particularly in Physick. 'Tis well known that he bought the secret of the Jesuits' Powder and made it publick." It would seem that towards 1679 an Englishman named Robert Talbot cured Louis XIV. of intermittent fever by a secret remedy, which the convalescent monarch gave him 48,000 livres (with a life pension and a title) to disclose. It was cinchonabark, and afterwards described in a book as the "English Remedy for the Cure of Fever, published by the King's Command 1682."—*Chemist and Druggist*, Dec. 25.

A PECULIAR FABRIC, which may find a use for many purposes, is made in Brussels. It is flexible, transparent, and impervious to water. This textile material can be washed off with cold water, like a glass pane, by means of a sponge, and is mainly to be used for portieres, window shades, umbrellas, &c. The patented process for the production of this tissue consists in filling the meshes of a wide-meshed fabric, such as muslin, with chrome gelatine or with a similar material, and then rendering the chrome gelatine insoluble by exposure to light. The fabric is then coated on both sides with boiled linseed oil or fat varnish: the treatment with chrome gelatine and linseed oil is repeated several times, and the fabric is ornamented by printing.

PEARL FISHERY IN WALES.—Sir Walter Besant (in the *Queen*) is responsible for the following:—

Are there any people in these modern times who carry on the old Pearl fishery of the River Conway? I have come across a few notes on the subject. There was an extremely ancient fishery here, dating certainly far back before the Roman conquest. It is said that Julius Caesar obtained while he was in the country a breastplate set with pearls from the Conway, and offered it to the temple of Venus in Rome. It is also said that a fine pearl from the Conway was presented to Queen Catherine of Braganza by Sir Richard Wynne, of Gwydir, and that this same pearl is now in the Regalia. Lady Newborough, in the last century, possessed a good collection of Conway pearls, and in 1780 Sir Robert Vaughan appeared at Court, his hat adorned with a loop formed of Conway pearls. It might be worth while to collect a few mussels—it was in the mussel, and not the oyster, that they were found—and ascertain whether these interesting creatures have lost the art of making pearls,

OUR PLANTING DISTRICTS.

Three more District Reports of an interesting character for last year will be found below. In all three—Central Maskeliya, Pundaluoya and New Galway—crops, with few exceptions, were nothing to boast of. Pundaluoya, we are glad to see, is still going on with cardamoms—a crop which sometimes beats tea for profitable results. More coolies and cheaper rice are wants which we hope this year will see generally rectified. In our Maskeliya Report, we get the best idea yet supplied by any District statement, of how the weather during the past year interfered with tea crops and estimates: may it prove more favourable in 1898. From New Galway, the one staring piece of folly is the non-completion of the Railway Station connecting road. The longer it is delayed, the longer must the railway receipts suffer. We must always maintain that this road should have been made in 1892 by the Government before the opening of the Uva line, and without reference to the few planters concerned in any way. It is chiefly required in the interests of the Government and the native trading community of Welimada and adjacent villages.

The Planting Districts in 1897.

PUNDALUOYA DISTRICT IN 1897.

WEATHER.—On the whole very favourable. There have been no very long spells of drought, nor excessive wet and cold. August was the stormiest month.

CROPS.—Tea leaf generally considerably below totals at same date in 1896. The small acreage of coffee left in the district is all on the northern side of the valley (North Pundaluoya and Eton) and gave what must now be considered a fair crop.

CARDAMOMS are cropping well in parts: but heavy toll is taken of the fruit by petty pilferers—hiped and otherwise. The rats are perhaps the worst enemies, and difficult to keep in check.

LABOUR SUPPLY.—Though no very serious difficulty has been felt, most estates, with a few favoured exceptions, could employ with advantage about a fourth more than they have.

TRANSPORT.—There seems to be no difficulty about transport.

ROADS.—In fair order.

THE PRICE OF RICE has been exercising the minds of planters. The Chetties have taken advantage of the recent slip to greatly advance their charges, on the plea that they have been compelled to cart their supplies for long distances. Those who had to go to the Chetties have had to pay as much as Rs 30 per bushel.

No particular grievance.

NEW GALWAY IN 1897.

The weather generally during the past year has been very abnormal, a good deal of rain fell during what we consider our driest months, while hot February-like weather was experienced in November, and the past seven days have been rainless.

THE TEA CROP has not been startlingly good, though I hear of one estate that has largely exceeded its estimate. The very little good coffee left has cropped fairly well, but the area under this product is getting smaller by degrees and wofully less. Of cinchona the less said the better, but several tons of acacia bark has found its way to the tan yard and the demand for seed of this valuable fuel tree (*accacia decurrens*) has been pretty brisk, as locally grown seed is more reliable than imported which is often very mixed.

THE LABOUR SUPPLY, as far as quantity goes has been ample, but there has been more "moving on" than usual, which means higher advances and less work,

TRANSPORT AS USUAL.

THE AMBRAWELLA STATION ROAD will probably be finished to the *cul de sac* by 31st January, 1898, but official pig-headedness and Highland obstinacy combined still leave an impassable ridge away in the centre of the trace, while rumour has it that the station master at Ambawella will have to act the role of toll-keeper in addition to his present arduous (?) duties.

RICE AND OTHER SUPPLIES have been dearer than for many years past, but have always been procurable.

OUR CHIEF GRIEVANCE is the dishonest rupee which appears to have increased the bump of caution already pretty fully developed by our caterers, and when you see an English article with "price sixpence" printed on it, marked Rt 25 nett, it's enough to make anyone oave in and long for a planters' Co-operative Store with head office in Colombo and branches in the principal upcountry centres.

CENTRAL MASKELIYA IN 1897.

WEATHER.—The first half of the year just ended might be called nominal as regards weather. At this end of the valley, the rains from N.E. in April and May were disappointing, which is often the case in these months. The Castlereagh Trig range on the one side, and the Goweravilla and Peak range on the other, divide the thunder and rain clouds that come over from the Hortons and across Bogawantalawa giving welcome rains to the upper end of the valley and all round, but too often leaving us in our parched state with fine flushes drying up and going to bangy. The leaf came in steadily during the first six months and without any great rush in April-May. In fact the older tea gets, the steadier the leaf seems to come in, although two to three months in the Spring and the same in the Autumn are always heavier. The last six months of the year are invariably the poorest as regards flush, but the last half of 1897 was unusually so. The S.W. monsoon broke with the usual thunderstorm accompanied by wind and rain. This, we think nothing of, any time during June, July and August, but we look for a little sunshine in September and October, and generally get it to dry things up and start growth again; but this year, although there were only 36 days on which rain fell in these two months, there were only seven sunny days out of the 61, and during the whole time there was a cold bleak wind from S.W. keeping the temperature unusually low, which, succeeding the three monsoon months, retarded growth still more. With the advent of the N.E., November started pretty well, but this month as well as December did not do so well as usual.

The rainfall for the year was 124.55 on 188 rainy days against an average (for 20 years) of 141.50 inches. The half-yearly averages for the same period being

Jan. to June rain 55.60 inches—Rainy days 84

July to Dec. " 85.90 " " " 121

CROP—was in nearly every case short of estimates owing to the unfavorable weather. The quality in some cases varied a little, compared with previous seasons, but was on the whole fairly well maintained. The drop in the market was disappointing, but this we have to face and fight as we are doing, that is the market, but an artificial exchange is a direct impost much harder to bear, and I hope will soon be done away with.

TRANSPORT AND ROADS.—Cart transport to the railway station gives no trouble. The hoof and mouth disease talked of so much in connection with light railways and road trams is a bugbear. Our transport is as cheaply and more conveniently done than it could ever be by light rail or tramway. Our roads were never better kept or in such good condition. The cost of upkeep is a good deal more than it was a few years ago, but not more, I should say, than proportionate with the extra traffic,

Rice.—The heavy cost has been a great hardship on Ramasamy as well as on the estates. Few proprietors or Companies have been able to charge the full price, but have divided the loss with the coolies, which, under the circumstances, was a fair way of dealing with the matter.

RE-OPENING OF THE BAMBARABOTUWA-RATNAPURA DISTRICT.

The letter elsewhere on "planting, gemming and roading in Bambarabotuwa" reminds us of the wonderful transformation which is being wrought in this old coffee district through the agency and capital of Companies or capitalists represented by Messrs. Finlay, Muir & Co. We have not yet got the full returns or statistics for our "Handbook and Directory;" but we know enough to infer that "Balangoda and Bambarabotuwa" will ere long constitute a rising and important division among the sixty odd planting districts in our list. The neighbourhood of Balangoda was the first scene of operations by Europeans on that side of the country and so far back as 1838, land was selected there at an elevation of 1,800 feet, the luxuriant coffee in the surrounding native villages having attracted attention. In 1840 large purchases of land were made, out of which Massena, Pettiyagalla and New Pettiyagalla estates were created and later on Hatterabage and Lankabarony. But the crisis of 1845-47 brought abandonment in some cases, and the district, as a whole, never recovered a position of any standing until Messrs. Shelton Agar, Layard, Torkington and Bosanquet & Co. began in the later "Seventies," to give Balangoda a name as a tea district. Now we have an almost continuous line of estates from the neighbourhood of Ratnapura right on to Balangoda, lying between the Bambarabotuwa and Rat- and Walauwa gangas with a dozen more plantations detached along the road leading to Bogawantalawa. Altogether, some 25 properties are counted in the Rasagalla division (Balangoda proper) and some 15 in the Bambarabotuwa and Ratnapura division. A most important tea district it is bound to become very shortly. The huge "Hopewell Factory" (belonging to the Company of that name) is expected to turn out eventually 2½ million lb. of tea annually, and it is intended to be connected by cart road with Ratnapura, 40 miles distant. The late Mr. John Dent Young traced and partly-made cart road comes in usefully here. The machinery of the Factory is to be electrically driven and tea from a group of neighbouring estates is to be made in it. A better watered district there is not in the island; but it is puzzling to think what gave rise to the idea that the Walauwaganga had its source in Walawadowa block for which the Government exchanged at the rate of 3 acres of splendid forest for one,—the true source of the river (which runs through this block) being much higher up! The activity, life and business connected with the opening up of hundreds not to say some thousands of acres with tea in the districts referred to, need not be dwelt on. Verily an immense change is coming over this side of the Adam's Peak range, and if the Kelani-Avisavella railway is prolonged to Ratnapura to catch the traffic at the end of the 30 to 40 miles cartroad, its financial success will be still further confirmed. Indeed, we may be sure the several powerful Tea Companies in-

terested will want (and provide) a tramway on the new district road as soon as it is finished, in order to be ready to connect with the Government Railway.

FERTILIZING MANURES.

The fact that, though last year only about one hundred tons of all kinds of chemical manures were imported into Ceylon, this year that quantity is likely to be greatly exceeded, is proof of the attention that is being paid to this question by estate owners, agents and superintendents. Following our policy of drawing attention to anything that can benefit the planter, we today turn to Odam's Special Tea Fertilizer, of which we have the following guaranteed analysis given:—18 to 20, soluble phosphate of lime; 4 to 6 per cent of undissolved phosphate of lime; 3½ to 4 per cent of pure ammonia and 4 to 5 of pure potash. Mr. Keith Rollo, manager of the Wanarajah Tea Company, says of it: "The results have been excellent, as tea has immensely improved and given remarkably heavy flushes, and when pruned two months ago there was magnificent wood to prune on, which means heavy flushes for another eighteen months at least."

The excellence of these manures has been certified by Dr. Voelcker, of London; Dr. Macadam, of Edinburgh; and others, including Mr. John Hughes, F.C.S. Consulting Chemist to the Ceylon Planters' Association. Messrs. Baker and Hall, the Ceylon agents have already this season booked extensive orders for Hatton, Kalutara, and Wattawala. To these districts in a very short time fifty tons of the tea fertilizer will be despatched. As an instance of what the manure will do we are assured that on part of one estate the yield was raised from 300 lbs. to 700 lbs. per acre.

PLANTING IN JAVA AND CEYLON. INTERVIEW WITH MR. FRANK ADAM.

As our readers are aware one of the visitors to Ceylon at present is Mr. Frank Adam who is very largely interested in coffee planting in Java. Mr. Adam came here in the beginning of December last and since then he has been travelling about the Kelani Valley, Kandapola, and Uva districts. His visit will extend till the end of February and during that time he will do some more visiting in the hill and low country. He was the first to interest Ceylon capitalists in coffee planting in Java—men such as Messrs. G. A. Talbot, J. H. Starey, D. & J. R. Fairweather, Wilson Wood, Rutherford, Reid, &c.—and the Glen Nevis Company started in 1892-93 is doing so well that those interested are, along with Mr. Adam, now engaged in taking steps to float a Company here to start a further block of similar land in the same district of Java as the Glen Nevis Company. That, and the extension of this Glen Nevis Company, he explained to one of our representatives, who interviewed him, was the object of his visit to Ceylon.

SIGHING FOR THE COFFEE DAYS.

Asked about his impressions of Uva he said:—I have met a good many old coffee planters and one and all of them sigh for the coffee days again in preference to those of tea. With regard to coffee here, I speak with a certain amount of reserve because the situation of the island, the soil, and the climate are entirely different from Java; but my impression

from what I have seen and from what I have heard from old planters is that one cause for the decadence of coffee here is that the plant was forced and grown under unnatural conditions—that under those same conditions the tree in the magnificent volcanic and humus soil of Java would have a chance of a longer life and a chance, with proper remedies, of recovering itself. From what I have seen the soil here is not altogether what coffee loves, but as I have said I speak with some reserve. When I say that coffee has been forced here I mean that it has been grown without shade. In Java we grow the coffee entirely under shade. In the second place until I came here I never understood the meaning of what Ceylon men said when they talked of pruning and handling coffee. That to me is another means of forcing the tree and thereby taking as much as possible out of it; and while it gave good crops as long as it lasted that rendered the tree less able to withstand any outside attacks. Our

METHOD OF CULTIVATION IN JAVA

is to have no topping at all on high elevations, while on lower elevations we top from 5 to 6 feet leaving a flat surface on the upper portion of the tree, and we do not go in for such an unnatural process as pruning and handling. That is in contrast with what I have seen in Uva where they top the tree at about 2½ feet and leave the head of it exposed to the full force of the sun and the air. Another thing I notice is that the coffee, or what remains of the coffee, is growing in some places on slopes amongst boulders and stones. Uva planters seem to fancy that the worst spots for growing coffee are in the sheltered places at the foot of slopes. In Java such steep slopes abounding in boulders and stones would be looked upon as unplanted, and some of our best coffee in Java is grown in the very spots at the foot of slopes, which Ceylon planters, as far as I am able to judge, seem to condemn.

THE SOIL.

Then in Java, the soil especially where we are, is composed, for the most part, of deep vegetable humus mixed with volcanic ash. Going through the jungle, one is able in most places, to put a common walking-stick up to the head into the ground without resistance. Whereas it seems to me in Ceylon a good deal of the fertility of tea is owing to the climate; we in Java, in addition to our having a good climate, have an advantage in the superiority of our soil.

WHAT COFFEE CAN DO IN JAVA.

I will give you an instance of what coffee can do in Java. The Pioneer Company—that is the Glen Nevis Company—started by Ceylon people was first cleared or planted in 1892-93, and the last clearing was completed in 1894-95. At the end of 1897 over a cleared area of about 615 acres under coffee there was produced a crop of the gross value of £22,000 sterling. The amount yielded to the end of 1897 from the first year's clearing (1892-93) showed the equivalent of production of 15 cwt. of coffee per acre. At the end of the third year the land produced on the first year's clearing 5 cwt. an acre; at the end of the fourth year 7½ cwt. an acre; and at the end of the fifth year (1897) it produced the equivalent of 15 cwt. an acre. The proprietors are so well pleased with the results that they are putting all the profits into further clearing, the estate having a large jungle reserve. As regards

THE RAINFALL

it is very well distributed, not one month being without a certain proportion of rain. The heaviest rain-fall is from October to March inclusive, and the average annual rainfall is from 85 to 87 inches. As regards

THE TEMPERATURE

the observations taken at six o'clock in the morning, mid-day, and 8 p.m., in the verandah of the Superintendent's bungalow showed a range at 6 a.m., of not lower than 67 and not higher than 72 Fah: at mid-day not lower than 75 and not higher than 84; and at 8 p.m., not lower than 72 and not higher than 78.

CONCESSIONS BY GOVERNMENT

are not granted to the outside public but only to Dutch subjects and foreign subjects resident in Netherlands India. The lands, acquired by the Ceylon planters were therefore obtained through myself as a resident, having had 23 years' experience of Java. The conditions upon which the Government give the land are very fair, but they are very slow in making grants. They alienate no land. The land is given out by the Government on a 75 years' lease and if nothing is said to the contrary at the end of the lease it is renewable, so that it is practically ownership that one receives. The Dutch law allows the mortgage of these lands in the same way as freehold property, subject of course to the conditions of the concession. No tax of any kind is payable until the end of the fifth year, when an amount is levied, which varies, but which may be put down at a maximum of one Java guilder (equal to 1s 8d) per bouw, which is equal to 1¼ acres. No obligation is imposed as to bringing the land under cultivation. In British Colonies you are obliged in most cases to undertake to bring so much under cultivation, with a certain time, but in Java there is no such stipulation. As regards other taxes there is no tax levied, until the estate comes into profitable bearing, when the usual income tax is levied which is somewhere about 2 per cent. The Government reserve to themselves all rights to minerals on the lands and also the rights to open roads and water-courses, subject to compensation being paid to the concessionaires. They will not permit the manufacture on the land of salt, which is a Government monopoly, or the cultivation of the poppy for opium which is also a Government monopoly.

REPORT BY A CEYLON MAN.

A well-known Ceylon man, who is also interested in coffee in the Straits,—I refer to Mr. Donald Mackay—was down in Java and after seeing the lands reported most favourably on them. With regard to Glen Nevis he said that the soil, situation, and growth of the clearings were so far, beyond that of any plantations he had seen in many of the countries with which he was acquainted and the reality was better by far than the descriptions of his Ceylon friends had led him to expect. The sheltered situation, encircled on all sides by mountain ranges, the uniform richness and depth of the dark volcanic soil, and the luxurious growth of trees from two-and-a-half to four-and-a-half years old could hardly be excelled, if it could be equalled, by Arabian coffee in any part of the world. The Liberian coffee trees had made fine progress. As regarded the cacao trees he was inclined to think from their appearance, that they might do better next year (1898) than progress had led planters hitherto to expect. So far

as his information went, the climate of the district generally was comparatively healthy; there did not appear to be much malaria; and the outbreaks of cholera which had been recorded were due more to preventable causes such as carelessness of the coolies themselves, than any unhealthiness arising from situation, soil, or climate, or water. Continuing Mr. Adam said:—The total acreage planted on Glen Nevis and the neighbouring estate by the same proprietors, up to the end of 1897 was about 1,400 acres of which two-thirds are in bearing. Off this acreage the gross value of the crop for 1895, 1896, and 1897 was £35,000 sterling.

ARABICA AND LIBERIAN COFFEE.

Our experience is that we obtain much more favourable results from coffee Arabica than Liberian coffee. Liberian coffee has been planted in these concessions experimentally but our attention is devoted to Arabica. Liberian coffee experimentally is doing very well, but the Arabian is what we depend upon. We argue that as long as we can find good land to grow Arabica it is better to grow that variety. As a fancy coffee it has very few competitors and we think it much better to leave alone Liberian which may be classed among the coffee of the many and not of the few. The wisdom of our doing so is evident from the fact that during the recent drop in coffee, such rough varieties as those of Brazil, Santos, Liberia, &c., experienced a very heavy fall, while the fall in fancy coffees such as Java, Ceylon Plantation, Guatemala was not appreciable. In fact since I came to Ceylon I have seen a quotation of bold, coloury, yellow Liberian in London at 44s per cwt. while Ceylon Plantation, which is very much the same preparation and quality as Java private estate coffee, was quoted in the same market report at 100s to 102s. Comment upon that I think is needless.

GEOGRAPHY.

Java, for agricultural purposes, is practically divided into two portions. The Western portion which is nearest Batavia and the main lines of sea communication is the part which is mostly seen by the globe-trotter. The climate of this part is very humid and the soil, upon which tea in the uplands is principally grown, is stiff and red. The east end of the island which very few people take the time to run down and see and which is remote from the main steamer lines, is the Garden of Coffee in Java. There is direct railway communication from Batavia to Djemoei quite close to the extreme east and the line has been surveyed for a further extension from Djember (tunnelling through a mountain range) to Bangcawangte one of the principal stations of the Eastern Telegraph Company and the most easterly port in Java. It is from that port that the Glen Nevis coffee is shipped, the distance between the estate and the port being 38 miles, 25 of which are over a good Government post road and the balance over a good riding track. As regards

THE POPULATION

it consists in the first place of Sundanese (Aborigines) inhabiting the west or tea districts of the island. They are less hardy than the inhabitants of the east end of the island who are composed of Javanese (also indigenous) and Madurese who crossed over to Java from the island of Madura immediately adjoining. There are also Malays in Java on the western sea coast, the descendants of Malay pirates in days gone by. These people are not employed as labourers,

but as household servants, coachmen, &c. The total of the population is about 23½ millions. The labour supply is very good. We have our own labour difficulties, like the planters in every other part of the East, but these have been reduced to a minimum. When Sir Stamford Raffles was in Java in 1810 to 1812 the population was somewhere about six millions and the figures now show how the natives have increased and multiplied under the Dutch rule. In regard to

THE WORKING OF THE ESTATES

we find it better to have that done by Dutchmen and according to Dutch methods with an Englishman at the head of the whole affair. The system works better than employing Englishmen who are not acquainted with Dutch methods, customs and language. The wages of a cooly on a coffee estate average about 40 to 45 guilder-cents per day.

EXCHANGE

is on a bi-metallic basis and therefore we do not have the fluctuations to which silver countries in the East are subjected.

THE ROADS

are amongst the finest in the world and for the most part beautifully shaded on both sides with tamarind trees.

OTHER PRODUCTS.

The land grows sugar very well indeed; but owing to the continental bounties during the last few years and the change in the tariff duties of America that industry is in a very precarious state. Indigo grows very well in mid-Java on a limited area. I may mention that at an agricultural exhibition in Calcutta some seven or eight years ago I remember to have seen that five prizes were given for Indigo. The first, second and third fell to Java and the third and fifth to India. Java also produces tobacco which is grown on a limited area naturally on account of the humid climate which it, like tea, requires. It also grows tea, as I have indicated, also cacao, vanilla, nutmegs, cinchona, &c. In the west of Java there is some of the finest table rice in the world, and throughout the whole island, there is the ordinary native rice. Of late years petroleum has been discovered, principally in mid and east Java, and some of the Companies have obtained splendid results.

TRIP IN SOUTHERN INDIA: NEW NILGIRI RAILWAY.

Hill Grove Hotel, Coonor, Nilgiris,
South India, Jan. 11th 1898.

We arrived here yesterday at noon having come by kind permission to the foot of the Ghat by the new Nilgiri Railway. This railway, I am told, has been some 12 years in construction, but it is hoped that it will now be opened for traffic in the course of a few months. It is a very difficult piece of work. It is a narrow-gauge railway with cog metal in the centre after the fashion of some of the mountain railways on the continent. The engine goes up behind the train, and the cogs secure the train from slipping back in case of any breaking of coupling irons etc. The line is now complete with the exception of seven miles which as I have said, it is hoped, will be completed all the way to Ootacamund in a few months. It is almost certain there will be

some heavy rock slips here and there in the future, but let us hope that precious lives may be spared. This railway will probably be much used, and probably Coonoor and Ooty will soon grow in importance. With such a magnificent climate, and charming scenery there can be no doubt that these two places will become very important in a short time. Coonoor is about the elevation of our Nuwara Eliya, and Ooty is a 1,000 feet higher. Already rents are rising very high, and land which Mr. ———, could have bought at R20 an acre when he came here first, can't now be bought at R2,000. Mr. J. G. Gregson has just secured a large bungalow here called "The Lodge" as a home for missionaries during the hot season. The bungalow has good bedroom accommodation, and extensive grounds with pretty nooks under shady trees, and commands a most magnificent and extensive view. Mr. Gregson and his family will reside in a smaller bungalow during the hot seasons of the three years' Travancore work.

I have just tasted, at Mr. Thomas Stanes' bungalow, Springfield, some delicious strawberries gathered this morning from his garden. Mr. Stanes tells me that the *Tea* here, though of good quality, yields only about half the amount of leaf yielded in Ceylon, or about 250 lb. an acre. Coffee seems to do well.

We expect to stay here till Thursday morning, when we are to go on to Ooty till the following Monday. Then probably we shall descend to Coimbatore.

CEARA RUBBER.

The Madras Government has recently issued a resolution on the experimental cultivation of Ceara rubber in the Malabar district. The experiments have not been very encouraging but the Government is of opinion that the matter should be kept in mind and that it should be considered whether the cultivation cannot be improved. The following are the reports which form the subject of the Resolution:—

Report by M. R. Ey. V. S. Gurusuatha Pillai, Acting District Forest Officer, South Malabar, dated Nilambur, 6th February 1897.

'In January 1896 one hundred Ceara rubber trees were tapped in Iravallikavu both morning and evening, each tree was tapped six times, i.e. twice a day for three days and 10 lb. of rubber was collected which was valued at 1s 6d to 1s 9d per lb. in England.' 'In the latter end of December 1896, 309 trees were tapped and 24 lb. of rubber collected; the largest tree tapped, i.e. 3 feet 9 inches in girth gave 8 oz. of solid rubber and the smallest, i.e. 3½ inches in girth gave 1-8th of an oz.; on an average 1 oz. per tree was collected.' 'Method of Tapping.—A few trees were tapped by making incisions on the trunk of various shapes and little cups made from leaves were pinned underneath to receive the milk, but it was found that no milk could be collected in this way. The milk trickling down the stem from the incisions was after three days peeled off in long strips which gave a few grains of rubber per tree, but the rubber was of good quality, i.e. clean and very elastic and free from disagreeable odour.' 'The other trees were tapped as follows:—the large roots near the surface were laid bare, and incisions 1½ to 1 inch long and ½ an inch apart were made on the exposed roots with a hill-hook and the milk collected in little pits dug in the ground under the roots to receive the milk. The trees were tapped twice a day for three days i.e. between 6 to 10 a.m. in the morning and between 4 and 6 p.m. in the evening and on the next morning the milk was found to be coagulated in hard tongues. These were removed and the tree tapped again as before.' 'It was noticed that the trees bled

more freely in the early morning than late in the day; i.e. a tree tapped at 6 a.m. would bleed for 10 to 15 minutes, while those tapped later would only bleed for 5 or 6 minutes, as the heat caused the milk to set much quicker and clog the milk ducts. Again trees growing on moist alluvial soil bled more freely than those growing on dry soil, a small sized tree with a girth of 21 inches standing on good moist soil and little distant from the surrounding teak gave 4½ oz. of rubber, while a tree growing on dry soil and surrounded by teak though 37 inches in girth gave only ¾ oz. of rubber. Particular notice was taken of the trees tapped in January 1895, the incisions made then were completely healed and those that bled well then bled freely even this year. From this it is plain that soil and surroundings have a good deal to do with rubber-producing qualities of the Ceara.' 'In March and April 1896 attempts were made to tap but with little success, the trees bled but little, the weather being too dry and hot and the trees leafless, the best season to tap is between December and February.' 'From the experiment tried has been noticed that trees planted 20 yards apart i.e. 100 trees per acre (the soil being favourable i.e. deep moist alluvial soil) will produce on an average 4 oz. of solid rubber per tree per annum when 3 feet in girth in about 18 years.'

Report by Mr. H. Tireman, District forest Officer, North Malabar, dated Manantoddy, 29th Augt. 1897.

'Twenty-three Ceara rubber trees were tapped at the end of May this year. The average girth of these trees was 21 inches. The yield was 8 oz. of rubber. These trees were tapped three times on three consecutive days. They had never been tapped before. In July, during a break in the rains, 67 trees, all of which had been tapped last September, were again tapped once. Their average girth was 27 inches and the yield was 20 oz. I will do some further tapping after the rains are over. I do not, however, think that the Ceara rubber is of any use as a rubber producer, compared with *Ficus elastica* and *Hevea Brazillensis*.'
—*Indian Forester*.

NEWS FROM BRAZIL.

FROM AN EX-CYLON PLANTER—MR. SCOTT BLACKLAW.

Rio, 15th Nov. 1897.

Three things have engaged public attention in Brazil for the last six months. The Little Rebellion in the State of Bahia—the Low Price of Coffee—and the Diminished Value of the Currency. It has been

A BAD THING FOR THE COUNTRY.

This expedition alone cannot have cost less than 6,000,000\$, already a vote of 4,000,000\$ has been asked for from the Chamber of Deputies.

When the Vice-President began this struggle in December—by sending the forces of the Union to the aid of the State of Bahia, exchange on London was over ninenpence per milreis; by the time the struggle ended it had fallen to seven pence. That is from 26½ milries to a pound sterling to 34½. The par value is 8 mil. 890-reis). Whenever any political commotion occurs or when the Government adopts any policy which may lead to drafts of money on the Treasury down goes exchange; for it is well known that the expenditure can only be met by increasing "the promises to pay" either in the shape of a loan or in the issue of paper money. Paper money in this country is different from yours. With you anyone can demand to be paid in metal, and the guarantee is the deposit in the coffers of Government of sold silver, and your exchange is regulated more or less by the value of silver. Here there is no guarantee but the Government promise to pay, and one is forced to accept payment in this forced paper currency. A Bank note of an English or Scotch Bank says distinctly on demand the value to be paid in sterling. In Brazil metal currency that is gold pieces of the value of twenty milreis and silver milreis, are

to be seen occasionally; but they sell at about $3\frac{1}{2}$ times their value represented in paper—a twenty milreis gold coin can be sold for from seventy to seventy five milreis in paper! For a long time it could not be seen that it was the excessive issue of paper money that had lowered exchange. The popular belief was "Oh it is the English Banks that are bringing it down in order to make large dividends." The Government understand the reason now, for they want to sell or rent the State Railways, and apply the proceeds to the redemption of paper money. In the same sort of local arguing the present low price of coffee is not due to overproduction, but speculation and the grasping policy of the foreign merchants. This fallacy is beginning to be exploded too.

This leads me to the question of

COFFEE

to which I really intended to dedicate this epistle but was led by the current of circumstances to go off at a tangent, on other subjects not so interesting to your readers.

Coffee has been pouring into Santos and Rio at quite an unprecedented rate. Some days as much as 50,000 sacks (of 132 lb.) at the former and 30,000 sacks at the latter. For the season ending 30th June of this year (crop 1896-97) the shipments amounted in round numbers to 8,500,000 sacks (of 132 lb.)—That is to say 5,500,000 from Santos, and 3,000,000 from Rio—against 7,200,000 sacks from the two ports for season 1895-96, and 6,600,000 for 1894-95. For the ten years previous—with the exception of 1891-92 and 1892-93 when the shipments were in round numbers 7,300,000 and 6,400,000 sacks respectively—the average—in round numbers—has been 5,500,000 sacks (of 132 lb.) from the two ports. The effect of these heavy crops has been a great fall in the price of the product. The greater part of Brazilian coffee is shipped to the United States, where it is always quoted in cents, and decimals of a cent per lb. Coffee there and in Rio it is classed in numbers according to quality from No. 1 to 9. The Rio papers quote generally from 6 to 9. No. 7 in the average of Brazilian Coffee No. 6 is superior and No. 8 is inferior. Up till the end of Dec. '96 the price for that year was about 12 cts. per lb. for No. 7, and 11 cts. per lb. may be taken as the average for ten years previous to that—fluctuating a good deal but seldom falling below that figure. Since January of this year the price has continued to fall steadily until in November this year No. 7 was quoted in New York at $8\frac{1}{2}$ cts. per lb.—and with the prospect of a million more sacks from the two ports—this increase being from Santos alone—the price is not likely to rise.

With regard to

THE ESTIMATE FOR 1897-98

opinions differ. A British exporting house telegraphed to London a few days ago—the fact being noticed in the Rio papers—that the Santos crop for 1897-98 would be 6,500,000 sacks (of 132 lb.) Rio which receives coffee from Minas Geraes, and Espirito Santo States—in addition to that of the State of Rio—will not ship less than its average quantity—3,000,000 sacks.

The State of Rio gives alternately large and small crops and this will be its small crop year, but on the other hand new plantations have been extending in the two sisters States at a remarkable rate,—justified of course by the substantial prices ruling for some years previous to this—which will more than make up for the yearly diminishing crops of the State of Rio de Janeiro.

Every year about this time (Oct., Nov. and Dec.), we see in the newspapers reports of there having been during the flowering season too much drought or too much rain, which has destroyed a great part of the embryo fruit, but somehow the yearly extending clearings—especially in the State of Sao Paulo—are seldom taken into account. The acreage in Sao Paulo of planted coffee has more than doubled during the last ten years, and until this check of low prices, and consequent inability to raise money, new plantations

will still continue to extend, for there in the far West there is any quantity of forest land, and near a Railway.

I notice in the newspapers as referring to what I mention above the following—"A Coffee Commission Agent in Santos, an educated and practical man, who has been taking a run through the Coffee Zone, affirms in a letter sent to us, that the Planters cannot at present count on anything but a small crop."

"A great part of the blossom has not set in consequence of a southerly wind which blew during the opening of the flower."

The same paper adds a letter from a Planter in the interior to a commercial house in the town of Sao Paulo:—

"The crop of 1898 will be one of the smallest we have had since 1860. The flowers of August and September are completely lost, a flower is showing for this month (October), part has already fallen and the other part is in spike. It appears the plantations will flower later, say the end of December and January, which will be a great inconvenience to the Planter."

When I was Coffee Planting in these parts it was not customary to count on either too early or too late flowers; from the later end of September to the beginning of November was the flowering season, on which to estimate crop. I do not think the seasons have changed much since then.

The question remains—can coffee planting in Brazil pay at the present low price of the article? The consideration of this must be left to a future communication. The same as regards the supply of Labour.

A. SCOTT BLACKLAW.

OUR COMMERCE FOR 1897.

II.—IMPORTS.

The fluctuations in Exchange have made business in Imports from sterling countries of a somewhat risky nature. An occasional rise or fall of one penny in the rupee brought a disturbing element among prices, and it may be safely assumed that dealers and consumers benefited accordingly, to the disadvantage of importers. Prices locally become depressed with any important rise in Exchange, but on the other hand when Exchange falls, it takes a considerable time to get prices up again. Business in Imports is at present much impeded by the tightness of the money market, and until rates of discount are easier sales must be small.

COTTON GOODS.—During the past year the tendency of prices of Cotton Goods was downwards and the following figures show the fall in the more important qualities:—

	Per Cent.
Grey shirtings, a fall of ..	$7\frac{1}{2}$
White .. do. ..	8
Prints .. do. ..	20
Coloured woven goods do ..	10

The fall in prices of prints is partially due to importation beyond the Island's requirements, and the losses sustained from recent forced sales will no doubt prevent a recurrence of oversupplies. It must be borne in mind that the off-take in the Island is a limited one. During the first nine months of 1897 there were bonded 495 cases of printed cottons, as against 362 cases during same period of 1896, showing an increase last year of nearly 100 per cent. A large crop of American cotton (probably the largest on record), coupled with every promise of a good crop in 1898, has kept prices in Manchester and other manufacturing centres at a very low level. Manufacturers appear to have bought largely both for immediate and forward supplies, and it follows that there will be a very large production of cotton goods this year at cheap prices,

ESTATE SUPPLIES.—Prices in general have been steady. Tea Lead became dearer as the year closed and is likely to continue dear for some time. Tea Chests have been in ample supply and prices were much lower on the average last year than was the case in 1896.

METALS.—A large and steady business has been done in iron and other metals. Prices of bar-iron at home were a little dearer, but the variation has not been great. Hardware has been imported steadily, but business in this is of a hand-to-mouth character.

SPIRITS.—The bazaar trade in Spirits has been a large one, but it is questionable if this trade is in a healthy condition. More than one dealer has failed to meet his engagements during the past year, and the readiness with which continental exporters shipped cheap liquors for sale on consignment, will no doubt be lessened when returns are received. The following figures for the first 10 months of 1897 and 1896 are interesting:—

	10 Months 1897.	10 Months 1896.	
Entered for Home	2,113	1,420	Cases Brandy
Consumption	1,939	4,114	" Gin
	6,592	5,386	" Whisky

The taste for gin is apparently on the decrease, whereas both brandy and whisky show increased demands.

RICE.—The year 1897 will be memorable as a year of dear rice in Ceylon. Soolye rice at the beginning of the year was worth R9.50 per bag whereas in September the price had gone up to R10.50 per bag. Other qualities of rice were correspondingly dear. As the year closed, however, prices gave way considerably (about R2 per bag) and with a large crop in Bengal and Burma, we may look for a continuance of cheap rice for some time. Some fear was held of a poor crop in Southern India, but recent rains have dispelled any fear of short supplies in that district.

COAL.—Indian Coal continues to be imported in largely increasing quantities, to the exclusion of English and Australian Coal. Cheapness is the great point in Indian Coal, and the quality of output is on the average better than in former years. It may be noted that Indian Coal is being largely used by local mills in place of firewood which has become scarce and dear. Local consumers can obtain supplies of good Indian Coal from R14 to R15 at the Wharf.

OUR STAPLE EXPORTS FOR TEN YEARS AND DISTRIBUTION FOR 1896 AND 1897 :

NATIVE PRODUCTS.

On page 539 we dealt with the figures relating to the Exportation and Distribution of the principal products of the Coconut palm, and showed that the steady development of business, from year to year, had evidently been hindered by the low prices and slack demand ruling for Coconut Oil. In contrasting the smaller shipments of Oil last year with the figures for 1894 and 1892, we remarked that, had the prices been better and the demand brisker, there was no reason why we should not have exported as much Oil as in 1892, with perhaps a slight reduction in some of the other products. A careful analysis of the figures shows that the last qualification requires revision, as the excess in Oil-exports of 1892 represents a far larger number of Nuts than is represented by

the development of business in Desiccated Produce and in Nuts in the shell; while in Copra, too, 1892 beat last year. The result is that the shipments of produce in 1892 show an excess, calculated in Nuts, of about 48½ million Nuts, over the exports of 1897. So that, so far from there having been an advance, there has been an actual falling-off! The figures are instructive, and not the less so because they were unsuspected, and we place them for the two years, as represented by Nuts, side by side to facilitate comparison:—

	Exports in 1892. Nuts.	Exports in 1897. Nuts.
Oil ..	275,488,500	204,800,000
Desiccated ..	11,549,172	36,163,356
Ripe Nuts ..	9,717,386	13,610,508
Copra ..	30,148,160	23,878,624
	326,903,218	278,452,488

The above figures are based on the calculation that a cwt. of Oil is equal, on an average, to 500 nuts; a lb. of Desiccated kernel to 3 nuts; and a lb. of Copra to 2 nuts; and they show diminished exports in 1897 to the extent of 48,450,730 nuts as compared with five years ago! The Island's production having decidedly grown in that period, the shrinkage in exports must be referred to a slack demand, leading to a fall in prices which resulted in the retention for home consumption of a larger proportion than ever of the coconuts produced in the Island; and home consumption represents an enormous quantity which it is most difficult to calculate accurately.

We have not included the exports of Poonac in the above calculation, as Poonac is, in a sense, a waste product, the output of which depends on the output of Oil—every cwt. of Copra yielding 2-3rds the weight of Oil and 1-3rd of Poonac; but the inclusion of the figures will not avoid the general conclusion. In correspondence with larger exports of Oil than in 1895 and 1896, last year shows more Poonac sent away; but we never rejoice at the growth in exports of a substance, every pound of which is needed in the Island for the feeding of stock, and for increasing the productiveness of the soil. So long, however, as the prices now ruling are maintained—averaging about R80 per ton—only working and milch cattle, owned by the well-to-do or the more enlightened classes, will be fed with the stuff; and it is not surprising that nearly 200,000 cwt. of Poonac were exported. Our largest customers were Belgium and Germany, which took over 90,000 cwt. each, the United Kingdom being content with 4,846 cwt, Italy and Australia being the only other countries, which took this product in small quantities. It is said to enter largely into the production of special cattle food; but whether it is given to stock as imported into other countries, or "made up" in attractive forms, it is curious that we should be sending away any cattle food at all, while importing from India immense quantities of gingelly poonac, cotton seed, cattleoid and bovinia, which are regarded with more or less favour by different people for cart-cattle and milkers. The other minor products of the Coconut palm are rope, yarn, and fibre,—in all of which a fair average business was done, the exports of every one of them having been exceeded once or oftener during the decade. Looking to the large number of small Coir Mills which have been erected in

various parts of the Island, the comparative stagnation in exports may cause some surprise; but the local consumption, especially of rope, must be immense; and herein consists alike the value of our chief Palm and its safety, that the home demand for its products is continually growing and that their circulation adds to the health and industry of the community. The United Kingdom continue to be our largest customer for Yarn and Fibre, taking away about two-thirds of the total exports; but of 11,732 cwt. of Rope exported, no less than 11,486 cwt. found their way to Singapore.

Of the other lowcountry products, the next in importance to Coconuts is Cinnamon; and that has shown a steady development for some years now. We have long regarded the increased production of the spice, which is so closely identified with the very name of the Island, with much the same feeling with which we contemplated the growing output of cinchona, after receding prices had reduced the profits from it to a minimum, and indeed wiped them out almost entirely; but the increasing output of cinnamon the past four or five years has not caused the usual uneasiness. Prices, which had run down seriously through over-production, began to look up since 1893, and the larger exports, which have been stimulated by the better prices, have not led to a fall. It is reasonable to believe that the demand which has continued notwithstanding growing supplies, is a real demand and has not been created for speculative purposes. Yet, growers who contemplate extensions would do well to note that the last three years have shown larger exports than were ever before recorded; that in 1897 both Quilled Cinnamon and Chips have separately shown the largest quantity ever exported; and that a spice is a luxury on the advancing demand for which the same reliance cannot be placed as on that for articles of diet and necessities of life. On the other hand, enquiries have reached the Colony about Cinnamon from London which indicate faith in its future—one English capitalist wanting to invest £1,000 in any Ceylon Company Limited for the production of Cinnamon! A satisfactory feature, too, apart from the maintenance of prices in the face of growing supplies, is that Cinnamon counts almost every nation among its importers; but the fact that less than one-half of our production is now taken by the United Kingdom, shows how the Suez Canal has diverted trade from London.

The exports of Plumbago have been fairly satisfactory and so have prices; but higher prices have ruled before now, and if there be a reversion to them, there is no reason to suppose that we shall not be able to send away more than the 357,257 cwt. we did last year, of which the United Kingdom took 159,675, America 88,810 or about one-half the previous year's supply, and Germany 63,518. The figures show a falling-off in the trade in Ebony (due, no doubt, to the gradual exhaustion of the supply); in Sapan wood (in which there ought to be expansion, if the value of the tree on boundaries is duly appreciated); in Palmyra fibre (in the collection of which much destructive work has been done); and in Kital Fibre, which ought to show better figures. Cinnamon Oil shows a considerable increase, and is capable of further expansion. So also with Citronella Oil, which is much in demand now for perfumery and about the different qualities of which there are great dis-

putes in the chemical world at present. Considering the scarcity of money during the larger part of last year, and the interruption to trade with India, caused by the plague and famine, there is every reason to be satisfied with the position of Native Products, in which, however, we hope to record more substantial progress during the present year.

PLANTING NOTES.

RUBBER—says Messrs. S. Figgis & Co.—has been a capital market at advancing prices, which are 3d to 4d per lb. higher than a year ago for mediums. Supply reduced from Zanzibar, increased from Borneo and Penang.

THE CEYLON TEA CORPORATION LIMITED.—We direct attention to a report in our daily issue, and *Tropical Agriculturist*, of an extraordinary meeting of the shareholders in this Company and to an interesting statement by the Chairman, full of praise of Doteloya and Penylan estates; but not much reference is made to the other properties of the Corporation.

CEYLON LAND AND PRODUCE COMPANY.—The report of the proceedings at the annual meeting of this Company—see our daily and *Tropical Agriculturist*—makes pleasant reading in view of the continued prosperity of the Company. The Acting Chairman (Mr. Wilson being in Ceylon, was able to give a good deal of information about cacao, which is of special interest at this time. The present Company seem to be very fortunate with this product; but not so with Liberian coffee, which is not regarded with favour.

THE CEYLON PROSPECTING SYNDICATE LIMITED.—In our Daily and *Tropical Agriculturist* we give a report of the proceedings at the annual meeting of this Company last month. As will be seen from the speech of the Chairman (Mr. A. W. Lawder) the Syndicate are now in possession in Ceylon of 191 acres of free hold property which is reported to be good gemming land and in order that their work may be prosecuted vigorously and on a large scale they have had plant manufactured for dealing with the alluvial gravels of the island in a manner hitherto unknown locally. Capt. Pilkington, who followed the Chairman, spoke in a most hopeful manner of the possibilities of the gemming industry here, the position of the Company being all the more favourable, in his opinion, that they had the sole right of using Mr. Lockhart's machinery in the island. Several of the shareholders who took part in the proceedings expressed themselves in terms which must have been very gratifying to the directors in regard to the wisdom of carrying on operations on an extensive scale and as to the suitability of the plant; and Mr. F. L. Shand gave the meeting the benefit of his experience in gem-mining in the neighbourhood of the Company's property. He alluded to the "Golden Grove," "Everton" and "Rauweltenna" properties and expressed his belief that the rich gem-bearing gravel which existed there, extended over the Company's land—the illum of which he valued at 10s per ton. The Managing Director produced convincing proof of the value of the land owned by the Company in a case of sapphires of a quality very scarce in the market and commanding splendid prices. It was his experience that valuable gems were constantly being found in ground adjacent to the recognised gem-pits. The proceedings altogether are of a very interesting and promising character.

Correspondence

To the Editor.

CEYLON TEA IN CANADA.

Toronto, Nov. 30.

DEAR SIR,—We had the pleasure of a visit from Mr. McKenzie, accompanied by Mr. Blechlynden, representing the Indian Tea Planters' Association. They are both we think very well satisfied with the wonderful progress Ceylon tea has made in this part of Canada, and is making in other parts. There is no article being offered to the public today, that is so largely advertised as Ceylon tea: there seems to be a craze among tea dealers to advertise. We ourselves were the originators of Ceylon tea advertising; in fact, before we took it up, no tea was advertised, but there are dozens of "Richmonds" in the field today.

We are sending you on with this, a couple of papers, one of last Saturday, and another of Monday, showing the extent to which Ceylon tea is advertised in Toronto.

The ousting of Japan teas in the Montreal districts is a harder task. Still, this is gradually taking place, and we have no doubt that in years to come practically nothing but Ceylon and Indian tea will be used in Canada.

In the United States we are making very great progress. We opened up branches there, in Buffalo first, at the instigation of Mr. McKenzie, and we had grave doubts as to the ultimate results; today we have none. It is only a matter of "holding on," when we shall catch the trade there, as we have in Canada. We have now offices in Buffalo, Pittsburg, Detroit, Rochester, Cleveland, and latterly Boston, in which place we had a fine exhibit at the Food Fair recently running there. This was very successful, crowded houses, afternoons and evenings; and it continued for over a month. The results to us have been magnificent. We have been shipping on in hundred or two hundred box lots until the other day, when we thought it best to get a carload of twenty thousand pounds ready, which we expect to despatch in a day or two. We have also about four tons to go forward to Buffalo, Pittsburg and Cleveland: in fact, we are kept at work night and day.

Mr. McKenzie has urged us on to push the business down by the Atlantic, in the Provinces of New Brunswick, Nova Scotia, and Prince Edward Island. You will perhaps understand that, although this is in the Dominion of Canada, it is a thousand miles further off than many parts of the United States that we are now in. Those provinces are exclusively black tea drinking districts, but the chief teas in use there are China Saryune Congous. We are making great efforts now to introduce Ceylon teas, and are meeting with fair success.

We venture to send this on to you, as it may be interesting to many of the planters.—We are, yours truly,

THE "SALADA" CEYLON TEA COMPANY,
P. C. LARKIN & Co.

[The Advertisements are large and attractive and are an undoubted evidence of the earnestness of the Company, in pushing our teas.—ED. T. A.]

TEA GROWING IN RUSSIA.
ITS FUTURE, AND EFFECT ON BRITISH
GROWN TEAS.

DEAR SIR,—While travelling in Sweden I met a gentleman who kindly gave me a letter of introduction to Mr. Popoff of Moscow, the proprietor of a tea plantation in Russia so I decided to visit Moscow, and if possible see the tea plantation.

AT ST. PETERSBURG.

After a very pleasant stay in Stockholm I took steamer for St. Petersburg, where we arrived on the third day. After presenting my Passport to a Military Officer, who took a keen interest in the valued document notwithstanding it was written in English, and he knew not a word, my baggage was examined and I was allowed to land.

At St. Petersburg my spirits were somewhat lowered; and all said it would be impossible for me to visit the tea plantation, as even Russians were not admitted, and they were very certain no foreigner would be allowed to see what was closed to them.

AT MOSCOW

Leaving St. Petersburg on the third day, I arrived at Moscow on the following morning. What a city to behold! Buildings of all sorts, and sizes packed in the smallest possible space; and as the houses are not numbered, the population close on a million, and few streets named, the new arrival must engage a guide as the "Svostchik" (Russian driver) has no idea of locality. To the Tourist there is much of interest: footpaths which in many places will not allow pedestrians to pass in single file, badly paved narrow streets the equal of which it would be hard to find. At every corner is an image of the Saviour, with a glass containing a lighted wick floating in oil. At each of these Altars the Svostchik takes off his hat and crosses himself some thirty times in the most devout manner, but trust him not, for in the same breath he will lie, and rob you in a manner that would put the lowest oriental in the shade. The leading merchants have their offices in the old city round which the famous Chinese wall still stands; the greater part of Moscow today, is outside the Chinese wall, and with few exceptions is as much behind the times as the old city.

CARAVAN TEA.

The cold was intense which made it all the more interesting to one who has lived for some years in the East. On the morning of the second day having procured a guide and droskie, I drove to the office of Mr. Popoff, where I met one of the chief clerks, who informed me that Mr. Popoff would be in at 2 p.m. I then drove to a large warehouse where a quantity of Caravan tea had lately arrived; the tea was in chests sewn up in hides with the hair still on, and placed next the chest! What with the close atmosphere and the smell from the hides (some of which were still damp), five minutes was as much as I could stand, and glad I was to get in the open. From that day I have, and always will carry my own tea when in Russia, and take good care it is not "Caravan tea." Ceylon, or Indian will be good enough for me.

TEA WITH A SLICE OF LEMON.

From my youth, having heard much of "Russia's tea with a slice of lemon," I was prepared

for something "extra special" on my arrival at St. Petersburg. Soon did I find it, as many other good old stories of Russia were, a huge delusion. The tea as drunk by the Russians, is very weak, with little flavour, and as a finish, it is served in thick tumblers. The custom of drinking tea in tumblers dates back to 1812. When the French soldiers entered Moscow they are said to have broken all the crockery, and only a few tumblers were found on their departure. In these the tea was served to the higher officials, and ever after it has become the custom. At 2 p.m., I again entered the office of Mr. Popoff, and was met by the chief clerk, who informed me, "Mr. Popoff was not in, he was away from home, and would not be back that day." I told the gentleman I would call the following day. "It will be of no use, Mr. Popoff is away, and will not be back." I thought it strange after my interview in the morning as then not a word was said as to Mr. Popoff being out of the city! I asked for Mr. Popoff's address, as I wished to write him? "Don't know, he is away, and may not be back for a month." My doubts were then confirmed; this gentleman must be a pure-bred Russian; not one word of what he has said is true. The following morning, I went to the side entrance, and thus avoided my friend of the previous day; sent in my card, and was shown into the Committee room where I met Mr. Popoff—"the gentleman who was away, did not know where, and would not be back for a month or more!"

Mr. Popoff the founder of the firm "K. & C. Popoff" (whose packet teas are known throughout the length and breadth of Russia), is very interesting to talk with, and all the more so to a Ceylon Tea Planter, as some of his ideas on the growing and preparing of tea are to say the least strange from our point of view. Mr. Popoff cannot understand why we in Ceylon, and India will spoil our teas by preparing them with machinery when we have so much cheap labour? On his plantation where the cost of labor is 1s. 6d. per day and free lodging it is possible they may use a roller and sirocco for the cheaper teas, but it will be much against his will as he knows it destroys the natural flavor of the tea!! Mr. Popoff says the difference between hand rolled tea and that rolled by machinery is as great as, "a good tune played by a fine orchestra, and the same from a German organ"! Mr. Popoff who had visited China, Java and Ceylon, intends to adopt the planting system of the former, as it is far ahead of that in Ceylon!!! The prayer of the Indian and Ceylon tea grower will be that not only Mr. Popoff, but others who may be interested in the cultivation of tea in Russia, will not only think, but carry out his ideas. Before leaving Mr. Popoff promised to send me a packet of tea grown on his plantation in the Caucasus, and a card of admission to the Superintendent who would show me round.

A few days later, the tea and card having arrived, I took the express for Odessa, where I arrived in forty-eight hours. During my stay in Odessa I had the tea valued by the principal tea buyer in the South of Russia; "good tea suitable for blending, worth six-pence per pound C.I.F. Odessa." With 1s 10d per lb. duty in his favor the Russian tea-grower could realise 2s 4d. The question is—should it pay to grow tea at that price what is the Government to do?

BATOUK.

Make it a Government monopoly, place an excise duty, or stand to lose five and a half millions sterling which is the revenue from the imports of tea! Knowing the Russian Government as I do, I am very certain it will not be the latter. Take petroleum from the wells at Baku (Caucasus). The price free on board at Batouk is 30 Kp (7½d) per pood (four gallons) the excise on that consumed in Russia is 60 Kp. (1s 3d) per pood, just double the cost of the oil. Tobacco grown in the Caucasus is taxed in the same way, and leaves the grower little profit. On the 13th November I sailed from Odessa for Batouk, where we arrived on the 18th after an interesting passage, as the steamer called at many ports including Sebastopol, where I visited the battle fields of the Crimea. Batouk has grown much of late, and now has a population of 24,000. That it has a great future no one can doubt, as not only is it the seaport for the great petroleum wells at Baku, the export from which in 1895 was 957,711 tons, valued at £3,634,000 sterling; but it is the terminus for the Siberian railway, the importance and future of which few have any idea. On landing only one fort at the entrance to the town is visible, but during my stay I discovered it to be a second Gibraltar with guns all over the mountain which forms a back to the town.

RUSSIAN PLANTATIONS.

Calling on the manager of Mr. Popoff's retail establishment I was astounded to learn that even he was not admitted to the plantation. He also informed me that the Minister of Finance at St. Petersburg, after driving to the plantation, was not allowed to enter it. The Svostchiks demanded double fare to drive to the plantation, as the snow in parts was deep, and they require four horses, so I decided to wait till the following day when I took train to Chakva and visited the first Russian tea plantation, which I now discovered was started by Colonel Solovitzoff in 1885. During my stay at the Caucasus I visited the Solovitzoff plantation, which has 100 acres of tea, Popoff's plantation with 250 acres, and the Imperial Domains plantation with 150 acres. Colonel Solovitzoff, a retired Officer of the Engineers, was the pioneer tea planter in Russia. In 1885 he planted 36 trees that were imported from China; with the seed gathered from these 36 trees, 250 out of the 500 acres in the Caucasus have been planted. The much-prized seed bearers stand three feet high, and are to be seen in front of the factory; that they will each year bear seed in abundance they may be assured, as they are a jât known only too well at great cost to many in India and Ceylon. I went through a clearing in its seventh year and found it not as far advanced as tea in Ceylon or India in its third year. This is partly due to the short summer, bad seed, and strong winds from the sea to which all the plantations are exposed.

MR. POPOFF'S PLANTATION.

Mr. Popoff has his plantation closely guarded. On arrival at the gate three Circassians, each armed with two swords, three pistols, and a rifle, presented themselves and demanded my permit. Handing my card of admission through the bars, two entered a hut to study the document, while a third kept guard. After some fifteen minutes, when they had satisfied their curiosity, one ascended the hill to the Superintendent's bungalow; another fifteen minutes in the sleet, and the messenger returned

with orders to open the gate, and for the first time a tea planter, and a British subject, entered the plantation which is kept such a profound secret. On ascending the hill I met the Superintendent, who showed me round the plantation, which has cost over 800,000 Rbls. (£82,000 sterling). It reminded me very much of the hill paddy-fields in Ceylon, as all the plantation is laid out in terraces five feet broad, the cost of which must have been very great, as the land in parts is steep. I saw tea trees from India, Ceylon, Java, and China, all of which looked well, notwithstanding the two feet of snow which lay on the ground, and the severe weather which had set in unusually early this year. Only a small area is planted with seed from India and Ceylon, and this has been condemned by Mr. Popoff. Perhaps his Chinese tea-maker thinks the leaves too long!

MR. CHINAMAN.

The Superintendent has no experience in tea, but informed me he is learning the work from their head Chinaman. This gentleman was brought from China and draw the nice sum of £50 per month. Along with him are ten other Chinese who, from all accounts, draw salaries that will enable them in a few years to return to their country and live on the fat of the land. Last year they imported 6,000 lb. of tea seed from China, out of which Mr. Popoff raised 49 plants. Mr. Chinaman may be counting on repeat orders till they raise the required number of plants!!

THE CAUCASUS.

In Odessa I was told that a large area suitable for tea was to be found South East of the Caucasus near the Caspian sea; but from what I have seen, and on what I believe to be reliable information, I report as follows:—South East of Caucasus, South of Baku, and near the Caspian sea there is a mild climate and fair soil, but as there is little or no rain, and all the year round is subject to violent wind storms it would be impossible to grow tea. On the East coast of the Caspian sea there is poor soil, no rain, and in summer violent hot wind storms that dry up all before them. On the Caucasus and to the north of Baku the winter has proved too severe. Last year out of the 5,000 plants put out near Tiflis not one survived to see the spring. South-West of the Caucasus, on the coast between Soukhom and Batoum, there are about a hundred thousand acres where it would be possible to grow tea, but at no part is it more than three miles from the sea, and in many parts the mountains are very steep close to the sea. The soil is good and rainfall plentiful, and in winter there is snow and sometimes twelve degrees of frost. In summer they often have strong winds with hail which does much damage to the tea. From the 1st of April to the end of September the bushes will sprout, but after July the flush is checked by winds and hail. Tea of the right jät planted in the shade might in the eighth year give 200 pounds per acre; with labour at 1s. 6d. per day, I fail to see where the profit would come in for the grower even with 1s. 10d. per pound duty in his favour.

THE GOVERNMENT PLANTATION.

The latest addition to the Government plantation is 50 acres, planted with seed; the trees from which it will never give 100 lb. of tea per acre. The cost of opening the land, seed, planting, and up-keep for first three years was, £5,750 sterling, which is equal to £115 per acre. To this must be added the cost of land £10 per acre and Superintendent's salary! The Superinten-

dents' estimate for this clearing is as follows:—5th year 60 pounds of tea per acre; 6th year 90 pounds per acre; 7th year 130 lb.; 8th year 200 lb.; and 9th year 250 lb. for which he hopes to get 3 Rbls. (6s. 6d.) per lb. It is possible that he may obtain his estimate for the first two years, but I am very certain he will be sadly disappointed in his returns for the following years; as also the price he will realise. At 3 Rbls. per pound the Russian tea grower would have a nice profit, but when he comes to realise 1 Rble. 8 Kp. (2s. 4d.) per lb. he will find the balance on the other side.

So India and Ceylon may count on Russia as a good field for their increasing supply.—Yours truly,
R. V. WEBSTER.

Sophia, Bulgaria, 10th December, 1897.

P.S.—Since writing the above I have received a valuation from Messrs. Gow, Wilson & Stanton, of the tea Mr. Popoff gave me while in Moscow from his plantation in the Caucasus "6d. per lb." This confirms the valuation of my friend in Odessa.

A NEW VEGETABLE.

Dec. 21.

DEAR SIR,—In the December number of the "Agricultural Magazine," which you publish as a supplement, the *Canna edulis*, with its various misleading names of *Tous-les-mois*, St. Vincent arrowroot and Queensland arrowroot, is referred to as a plant considered to be equal to, or more valuable than, the real arrowroot, and is said to be grown in Badulla and the Rayigam Korle. I brought this plant some time ago to the notice of our late Director of the Royal Botanic Gardens and have figured it and described its cultivation, with other plants not generally known, in some papers which I hope soon to send you for publication. Meantime I may mention that the distribution of the *Canna edulis* is very much wider than stated above: it is largely grown in coolies' and in natives' gardens in nearly every planting district. The tuberous roots are an excellent curry vegetable, and when dried and pounded, yield a large amount of flour which is used for cakes, etc. The plant, one of the most handsome of the *Cannas*, with its flame-coloured flowers and broad foliage tinged with red, is called by the Tamils "Valay sembu" (plantation yarn), and by the natives "Bât-sarana" (Refuge in Buddha). It produces no seeds and is grown from stools in the same way as cardamoms are usually planted.—Yours faithfully, Br.

CACAO CULTIVATION IN CEYLON: OUR OLDEST TREES; AND PRACTICAL EXPERIENCE: REASSURING NEWS.

Dec. 31.

DEAR SIR,—The intelligence (save the word!) is only startling in its silliness regarding cacao and its limit of age. There was fine cacao in bearing on Rothschild 20 years ago when I was S. D. there and I believe my old P. D. (J.G.C.), still wonders at its vigorous cropping. There are trees 40 years old in Peradeniya Gardens, and nearly 50 years old on Pallekelly. We have trees here 20 years old and only just in full bearing. They have been growing all these years and would touch at 30 feet apart. Udapolla and Eadella have trees a score of years old, 30 and 40 feet high with 40 and 50 feet spread, bearing grandly.

No! Cacao is good for a century. You try it, as the old man did with the raven.

Close planting has something to answer for. 16 by 16 is quite close enough for Forastero and alternate trees could be taken out when it is 13 or 14 years old and the field, left at 16 by 32, later on reduced to 32 by 32, and then cacao walks would be worked as orchards, and we should get twice and thrice the crops we do now. Jambed in 10 by 10 in the early days of inexperience, it is a wonder, worse has not happened to cacao, one of the very best investments a man can make. Bide-a-wee and we'll see a boom yet in Theobroma Cacao. "Calabacillo" is hardly a new name. It is the calabash shaped variety red and yellow and the most inferior but hardiest.

Possibly we have not the soil of some more favored cacao countries; but we have a climate it would be hard to beat, and I much mistake my fellow cacao Planters if they came in to any of the pests that have yet attacked their trees. Helopeltis was and perhaps is in some parts bad enough in all conscience but it is most arbitrarily local and nearly always confined to a few corners exposed to paddy fields, swamps or bare chenas adjoining.

Of canker we'll say nothing till the experts speak. The case is *subjudice*, but the disease is *not* incurable. It is *not* general, and it does *not* attack some varieties—at any rate it has not yet. Contradict most emphatically the utterly unfounded statement that "Cacao dies out, I may say, universally, when it reaches the age of 13 or 14 years" because facts prove otherwise and many Forasteros are *not full grown till past that age!*—Yours faithfully. C. G.

No. II.

Matale, Jan. 2.

DEAR SIR,—Our experience of cacao in Ceylon does not certainly limit its life to 13 or 14 years. The writer referred to by you contributing to your morning contemporary may well be termed a startler and can have no experience of Ceylon. The bold assertion "at any rate cacao dies out, I may say universally when it reaches that age"—(13 or 14 years) needs greater authority to support it, than the experience of the writer can claim. There are plantations in Ceylon where thousands of trees may be seen of 20 years of age at least still in their prime. While there is a tree in Kandy opposite the Military Hospital, on the premises now in the occupation of Dr. Keyt, which cannot be less than 40 years old. The late Mr. Blackett mentioned to me, when we were discussing this same question regarding the longevity of cacao, that he knew the tree from his earliest recollection of Kandy. Where therefore writing about the limit of life enjoyed by this tree, it would be more safe to rely upon such writers as Berthelink, than to take the statements of modern paragraphists writing from London.

The extracts from the Trinidad Agricultural Society reported by you are very interesting to cacao planters.—Yours truly,

A CACAO PLANTER.

SALT IN AGRICULTURE.

DEAR SIR,—I was very much interested in the discussion in Council on the Salt question and much cheered in the way the Government accepted the motion. It was over ten years ago that I attempted to get up an agitation for the issue of salt at cheap rates for agriculture in general. I pointed out to coconut planters that considering the natural home of the coconut palm, it became imperative for them to

apply salt freely to coconut trees growing inland so as to compare as nearly as possible with the natural conditions under which the palm grew. My agitation met with no response and Dr. Trimen, who was appealed to, pointed out to the analyses of Lepine as a refutation of my contention. He stated that the small quantity of salt a coconut tree required was supplied to it by one S.W. monsoon storm. I pointed out that apart from its manual value, salt benefitted vegetation by the mechanical and chemical changes it effected in the soil. Mr. Cochran's interesting analyses establish the necessity for salt as a manure for coconuts. It will be invaluable for application in the heavy and dry soil of many favourite coconut districts.

Wherever did the Colonial Secretary get his figures of the probable consumption of salt for agricultural purposes? They remind me forcibly of the figures of the estimate of goods traffic on the proposed Puttalam Railway. In both instances the figures are based on assumptions. In the one case the existence of so many acres of coconuts is a fact that that: salt will benefit them is a fact. It is therefore assumed that salt will of necessity be applied to all existing coconut plantations. I will be agreeably surprised if one-tenth of the estimated consumption will be reached in the near future.* Government may, I think, safely dismiss the fears they now run to entertain that should cheap salt be issued they will be unable to meet the demand.

I do not know whether it was under inspiration you wrote recently that in spite of the scheme for railway extensions sheltered by the Governor and in spite of what was placed before the Secretary of State for his consideration and sanction, there may yet be a possibility of the Chilaw-Puttalam route being adopted to the North in place of the Kurungala-Anuradhapura route. If it be so, it shows that the recent journey of the Governor has borne good fruit in that, it has convinced His Excellency that the better and more reasonable route had not been originally adopted. Everything seems to have been sacrificed to serve the cost of construction of a few miles of railway to reach the Terminus at the North. Given a cheaply constructed railway, statistics prove that it will pay. This news must prove very pleasing to the Puttalam resident who so persistently fights for a railway to his adopted home.—Yours truly,

MARAVILLA.

DAYS OF OLD IN UDA PUSSELLAWA.

Haputale, 5th Jan. 1898.

DEAR SIR,—I am glad to see by your New Year's Correspondent signing "Y.", that another of the small band of pioneers who first opened the Udapussellawa district, is still to the fore, "may his shadow never be less" and may he have many more happy New Years to spin us a yarn of the days of old; but if he will pardon me, I will correct him on a few minor points in which he has erred. On the 1st of January, 1858, I relieved poor "Dick" Crawford on Alnwick, James Wilson on St. Margaret's, William Boyd on Tulloes, and A. Vallance on Kirklees; we were a small band of four, who trod those hills and valleys in 1858, but your correspondent dates from a year or two earlier.—Browning opened Alnwick, the first 100 acres, another 100 acres being opened by Crawford, after which I got charge, but in a few months' time, I had to exchange billets with John Ward and go to Massena in Balangoda, both estates then owned by the Baron Delmar. James Wilson died in Stainton's Hotel

* Of course, a possible maximum has to be provided for.—ED. T.A.

without his leg being amputated, the Rev. G. Sprott and myself being with him to the last. William Boyd after leaving Tulloes in the Sixties went over to India, and for some years, managed an estate there, and some years after came back to Ceylon and died in Colombo as related; he was, I believe, a partner in the short-lived firm of Ackland, Boyd & Co., who collapsed in the forties. A. Vallance leaving Kirklees, had charge of the Peradeniya sugar estate, before his death and died in the island, I believe. I don't know your correspondent and should like to exchange greetings with him and tell him that the first tea plants I saw were some on Kondagalla estate before entering Nuwara Eliya on the Rambodda side, owned by the brothers Worms and on my taking charge of Kahagalla estate in this district at the end of 1858, I found a large nursery of tea plants or rather trees eight or ten feet high, planted by my predecessors Littlejohn and Sandy Davidson, but prior to this the late Mr. John Nietner, who came to the island in 1853 as Botanist for the Baron Delmar to introduce new products into Ceylon (when I was a clerk in the office of the late Mr. J. P. Green) went to China, brought over tea seed and grew them near Negombo on land of a coconut estate bought from Dr. Elliott then proprietor of the *Colombo Observer* as it was called. These with some tea grown on Rothschild estate, Pussellawa, by Messrs. Worms, the history of which you have given in your Directories, were the first tea of the China sort introduced into the island; if anyone knows of earlier introductions of the tea plants by private individuals you can I fancy tell us in your next *Vade Mecum* the Ceylon Directory for 1898.

J. A.

CACAO IN CEYLON.

Ukuwella, Jan. 6.

SIR, —*Re* Cacao dying out in 13 or 14 years, I remember seeing a tree at the lower bungalow Keenakelle, Badulla, in 1876, which was then some 15 or 20 years old. Is that tree still in existence? And what about the Peradeniya trees which must be some 30 or 40 years old? Truly a little knowledge is a dangerous thing. MC.

[The cacao tree on Keenakelle will be found described in our "Handbook and Directory." It is now not less than 40 years old and is flourishing 4,000 feet above sea-level! But, alas for Peradeniya trees, see a report elsewhere.—ED. T.A.]

DRYING TOMATOES—AND EXTRACTING FIBRE.

DEAR SIR,—I would be much obliged if through the *T. A.* I could get some information about drying or preserving tomatoes; could they not be dried the same as fruit and in the same kind of machine and what machine would be the best for a small quantity and cost?

Also how to extract the fibre from the pineapple leaf. Is there a machine to do it properly. I hear Death's machine only partially cleans the fibre; then what is the fibre so cleaned worth? And cost of hand machine, output of fibre per day, &c.—I remain, dear sir, yours faithfully,

TOMATO.

[Who can tell us about drying tomatoes? A "Desiccator" machine might suit the purpose. Experiments in Ceylon, in extracting fibre from pineapple leaves, have not been successful in yielding a paying result.—ED. T.A.]

DRYING TOMATOES.

Greenfield, Bambalapitiya, Colombo, Jan. 7.

DEAR SIR,—If you will put your correspondent in direct communication with me, I shall be glad to explain to him cheap and effective

ways of drying Tomatoes, and extracting Fibre from Pineapple Leaves.—Yours faithfully,

E. T. JENKINS.

[Our first correspondent is a planter in Sumatra, and he will be duly advised; but could the information not be given *pro bono publico* to include in our *Tropical Agriculturist*?—ED. T.A.]

CEYLON TEA IN AMERICA.

EXTRACTS OF LETTER RECEIVED FROM MR. WILLIAM MACKENZIE, CEYLON REPRESENTATIVE IN AMERICA.

From the Secretary, "Thirty Committee," Kandy.

SIR,—I enclose for publication extract of letters received from Mr. William Mackenzie, regarding his work in America.—I am, sir, your obedient servant,

A. PHILIP,

Secretary, "Thirty Committee," Kandy, January 8th.

I send some films showing in miniature an animated advertisement we have been flashing nightly in a very prominent position in New York. The figures are life-size and are shown in motion—just like the Biograph or Cinematograph in London. Thousands stand and look at this on the street.

The first shows a Chinaman offering a lady a cup of China tea. The second shows her ordering him out after she has tasted it and found it disgusting as her face in a photo—not included—expresses.

Next comes the *loose piece*: a Japanese offering his tea: then No. 4 where she again shows her dislike.

Then comes an Indian servant with pure machine-made Ceylon and Indian; she tastes it, is delighted and has a second cup.

The lady is an actress, and acts her part beautifully. We are trying to arrange to have the thing in several large cities, but it is difficult and expensive—while still novel it is very catching advertising."

I have been at Montreal to see —'s Canadian Agent. I made an arrangement with the Firm in London for a vigorous push in Eastern Canada to cost £1,500, of which our share is to be £500. I was led to this by the then existing difficulties of getting fine teas into the States. I say "then existing" because I am glad to say the difficulties have been removed.—A 26 sieve is now to be used, not a 16. This is entirely due to the very clever manner, in which Mr. Blechynden fought our battle while the importers were divided and each was trying to get his own in and others excluded. Mr. B. took the matter up, and carried it direct to Washington.

I have also been to Boston, where we were interested in some exhibits in a Food Show. The show was well attended and was most interesting. I am sorry to say I found while our teas were being advertised, greens, oolongs, and mixed were being served and sold. The excuse was the old one, "We cannot pay expenses unless we give what the people want. Much of this has to be winked at."

I enclose a letter showing how Salada Ceylon Tea (Larkin's Brand) has been progressing in Eastern Canada served from his Montreal branch. You will note the business has trebled in a year and his Manager is confident it will again treble during the next twelve months. A much smaller increase even will be satisfactory.

Instead of spending £3,000 a quarter, I propose to spend £7,000 during first half of next year and £5,000 during second half. Little can be done in July and August, as the weather is too hot, and everybody is away seeking cooler climes. If you agree with me arrange that £4,000 be remitted at end of December and £3,000 at end of March, please.

I have sent some advertisements and other matter in other envelopes.

The very low price of coffee is against us this year. It is being retailed at about half of its price two years ago.

3. I have not much to tell you this week. Dealers are holding off under the belief that there will be soon a fall in the price of the Tea. One paper indeed has a paragraph to the effect that wires from Colombo have already reached here, quoting a fall on the local market there. I have wired to London to ascertain the truth.

Mr. Blechynden and I went down to Philadelphia last week to visit a Food Show where our teas were being exhibited. As is getting too common we found "greens" and "mixed" being sold as Ceylon and India Teas. This is going on to a greater extent than we like, but it is difficult to stop it.

The largest wholesale grocers in America with 300 travellers have made up their minds to handle a Ceylon-Indian tea package—I see I mentioned this in my last letter—but it is now a settled matter, as they have ordered 10,000 lb. in one-and-one-half lb. packages.

Copy.

Letter referred to.

Toronto, Oct. 5th, 1897.

Dear Mr. Mackenzie,—I am giving you a clipping from a letter from our man, whom since hearing from you, we have kept down in New Brunswick, Nova Scotia and Prince Edward Island. You see we are not only introducing Ceylon tea in Canada and the United States, but also in France, through their Navy.

I am enclosing Japanese advertisements that appeared in the *New York Herald*, *New York Sun* and *Buffalo Express*; it is really poor advertising, although they have taken fine positions they are paying pretty sweetly; it is a column on the front page, in the *New York Herald*.

I am enclosing advertisements that appeared in last Saturday's papers in the city of Toronto, in all, fifteen in number. Ceylon tea is well advertised here, isn't it? I am ambitious to bring about the same state of affairs in the Provinces of New Brunswick, Nova Scotia, and P.E.I.; then we have Canada well covered, and I have no doubt that after two years work, and possibly less, there will be as large a consumption of Ceylon and Indian Teas in those three Provinces, as there is today in Ontario.

In Quebec Provinces we are making great headway and no mistakes. Last week was the highest week we have had in the city of Montreal; in Quebec Province our sales for the city were 1,810 lbs; in the country East of Montreal, 930 lb. making a total of 2,740 lb. I am just giving you below, what the increase has been in the Province of Quebec and thereabouts, which includes, of course, everything done from our branch there (Montreal)

	lb.		lb.
July 4 '96	517	July 3 '97	1,758
" 11	577	" 10	1,645
" 18	603	" 17	1,646
" 25	705	" 24	2,560
		" 31	1,861
Aug. 1	651½	Aug. 7	2,079
" 8	914	" 14	1,743
" 15	905	Aug. 21	1,764
" 22	791	" 28	2,416
" 29	411		
Sept. 5	505	Sept. 4	2,615
" 12	974	" 11	2,632
" 19	1,527	" 18	2,421
" 26	985	" 25	3,078
Oct. 3	1,040	Oct. 2	2,740
		9	3,346

This is very encouraging isn't it? Last week would have been very much larger for the Montreal Branch, but our traveller was home part of the time.

There is no doubt about it, that the same state of affairs will come about on the American side, but it will take time, as it has here. You would be surprised at the talk that goes on in Buffalo now. Very often latterly, our man will be received, when he goes into a store, with "Oh no, we don't want any more 'Salada,' we have got a Ceylon of our own now; yours isn't the only Ceylon tea!" . . . Of course, we never told them that it was, but they seem to have formed that impression themselves

and when some wholesaler came along and sold them a box of Ceylon tea, and they immediately jumped to the conclusion that they can displace "Salada" with this. We generally find that, in the course of another week or so if they are low in "Salada" when the man calls again, he gets an order, because people want what they are used to and know to be good and they won't take the loose Ceylon tea for it, that is, in most cases. We have the wholesales still sending in for small lots, but very small ones. The trade is a regular every day trade, but so small that I do not feel like keeping tab on it, although I am going to start now, and have books kept at Buffalo and Pittsburg, showing the exact sales every week. I did not keep this in Montreal for a long time after I had started, because it used to cost us about two dollars a pound to sell the tea. It is paying us a good round profit now every week, latterly never less than \$40 or \$50, and as big as \$76; and my man down there thinks he will soon be able to put another '0' to the end of it.

You will be glad to hear that, at the beginning of this week, we had 71 accounts in Cleveland and many signs up. We are now running in the "Press" there.

Mr. Larkins', manager in Montreal, tells me he feels quite confident the sales by October, 1898 will be 10,000 lb. a week (at the Montreal Branch) that is, that they will in the next 12 months treble, as they have done in the last year.

A large dealer in Philadelphia was shown a Ceylon sample—apokoe—a few days ago. He liked it, and asked how much there was left; but being told there was only 25 chests he said, I don't taste a tea unless there are at least 300 packages. He has been accustomed to buy from standards of China Tea. I send some samples of the advertisement, used in Canada by Tetley & Co., under our joint scheme for working the Eastern portion of Canada.

Also—The tea trade "Tussle" we are putting into magazines and newspapers just now.

I am going out west next week, Pittsburg, Chicago, Detroit, Cleveland, Buffalo, etc.

1st Dec., 97.

My last letter was that of 19th November, written before I went west. Mr. Blechynden accompanied me and we have returned much pleased with what we saw and heard. Much more interest is now being taken in our teas and the convictions are gaining ground that they have come to stay. Two or three of the largest importers still refuse to carry a stock of Ceylon or Indian, but they are constantly taking a few chests from those who have stock, showing that their customers insist on getting the teas.

You would have seen Gow, Wilson's circular showing the great increase in American importations during first nine months of this year, as compared with same months of last year, viz., 8,464,000 lb. as against 5,560,000 lb. Whether our estimate of 12,000,000 lb. is to be realized or not, time must tell. The recent rise in price, stopped many orders. I have heard of a few large ones sent to Calcutta, because low grade teas there are cheap enough to meet the limits given.

I am glad to say Lipton's managers, here and in Chicago, are again pushing vigorously, and are meeting with much success. Their recent progress with packet teas surprises themselves. I saw today a letter from a New York grocer asking for samples and prices and ordering 200 lb. Now Lipton's people had never solicited this man's trade, they had never even heard of him, but he evidently had enquiries for the tea. A letter which I enclose from Miss Parkinson gives her experience of the increasing interest created by our advertising.

Lipton and Franklin Macveagh & Co., of Chicago have been introducing our teas into dozens of towns, small and large, in the Far West. The latter firm assisted by us are advertising the Naban Ceylon Tea in the most important papers between Texas and Washington territory on the west coast.

It was chiefly because of the work done by this firm that I asked the Committee's permission to spend a portion of the Fund beyond Chicago.

The new regulations extorted by Mr. Blechynden are working favourably for us, but thousands upon thousands of boxes of China and Japan teas are being rejected. There is quite a panic among the importers of these teas. They had hoped to get rid of the rejected teas by dumping them in Canada, but there we have check-mated them. We started the subject in the press and went to Toronto to get the trade to take the matter up. I enclose a leader from a Toronto paper and today I have a letter from the Editor of the "Canadian Grocer" to the effect that the Government is on the alert, and that a large quantity was seized at Montreal yesterday. Today I hear a number of importers there, were trying to induce the Manager of an English Tea Firm here to take charge of the rejected teas and ship them to London to be sold by auction there. I am afraid that will be the field for most of the rubbish as blenders can buy it very cheap, and put it in their packets.

We are to write fully on the subject to the London Association.

Of course, we are making the most of the rejections in our advertisements, and by doing so have made the would-be importers very angry. One very angry representative of the class called yesterday at the office of the "Journal of Commerce," and threatened to prosecute the paper.

I hope to sail for England next week.

GAME PROTECTION IN CEYLON.

Madulkelle, Jan. 11.

SIR,—I am glad to see Mr. Farr's statement on the Game Protection Society. It shows that the Society is in a fairly good position, and that some good work has been done, and it is certainly not the fault of the Society that much more has not been effected. The Government, which is in the first place responsible for Her Majesty's dumb subjects, has been all along grossly negligent in its duties, and it would appear until we stirred it up about five years ago, was absolutely unaware that it had any responsibility or duties to perform towards these subjects.

We have had plenty of Ordinances passed. They cost the Government next to nothing, and are doubtless a salve to its conscience; but whoever heard of a single Ordinance connected with game protection, except that relating to elephants, and possibly buffaloes, being enforced?

As a matter of fact, it may be taken for granted, that the Ordinance so far as deer are concerned was never intended to be enforced; the Ordinance passed, but no machinery was ever supplied. It would surely be more consistent to repeal this Ordinance at once. The offence would at least be done away with; and Her Majesty would be the gainer in a few hundreds of law-abiding subjects.

I would strongly urge upon the Society to appeal to the Government for sanctuaries for game, say of 10,000 acres each, in the districts of Tamankadua, Binteane, Lagala, and various game districts; and for the appointment of rangers for these sanctuaries supervised by officers of the Forest Department with a substantial addition of pay for the extra work involved.

This, it seems clear to me, is the only way to protect deer in the big game districts. At present the Game Ordinance, with the exceptions I have stated, is a glorious farce. The Axis deer is rapidly being wiped out; and the Axis is *par excellence* the game of the great wilderness of the North-East and South-East. That game can be protected, and is only too susceptible of protection; I have good reason to know, having

for the last four or five years taken about 2,000 acres in hand, on my own account, chiefly Crown forest, be it noted.

In this sanctuary, by dint of thrashing every marauder, smashing his gun and shooting his dogs; I have succeeded in collecting and preserving a very respectable number of Sambhur and other game. They are, I say, susceptible of the protection offered, because they remain in spite of the fact that I continually hunt the ground for hogs, which I destroy both for the sake of the sport and for the protection of cardamoms.

The Sambhur very soon recognise the fact that they are protected. The result is that on any fine day, when the uplands are free of mist, you may see them, and a very pretty sight they are.

Beyond the sphere of protection you may look for a single shot for a long weary day and look in vain; because the intelligent officers of the Crown, who are supposed to be protectors of Her Majesty's property, seem to think that issuing licenses to vagabond estate coolies will conduce to the preservation of that property.

I have no hope whatever for the protection of game in the low-country except by means of great sanctuaries kept up at some expense, and under European supervision, and the Forest Officers and Government Agents are the proper persons to be entrusted with the work. Acclimatization should be actively pursued, and will I am sure repay labour. My own particular sanctuary has become a most interesting place in a very short time. I can show Sambhur in numbers, some Elephants, Barking Deer a few only, the altitude being great; wood-cocks, which I have never shot at, migrate annually, in increasing numbers, and as many as 4 or 5 may occasionally be flushed in a morning between January and May. Carp I have turned into a few big pools in the forest, and they are thriving; and later on I intend to try trout.

I heartily commend to the Game Protection Society as the result of my short experience, the formation of many such sanctuaries, not only in the low-country under Government protection, but in the mountain zone too.

If my protection has been afforded in rather a high-handed manner, I apologise to Her Majesty's representatives; but it has certainly had very good effect, and I propose to carry it out until matters "develop;" but, if I am bound down to keep the peace, and the *ruck* rabble of vagabond meat-sellers are let in to destroy Her Majesty's wild subjects in defiance of the law, and the deer and wild fowl disappear, it will be time for me to be shifting too from a land where such inconsistency in the application of law is permitted.

E. G. R.

CHEAP SALT FOR AGRICULTURE.

Jan. 11.

SIR,—“Maravila” in a recent issue on the said subject doubts the probability of the estimates of traffic reported by me re Railway to Puttalam. A simple denial or doubt would not carry much weight in any controversy unless substantiated by reason, in the absence of which I can afford to treat his effusions with silence.

I should on the other hand like to impress upon your readers that a railway to Puttalam will undoubtedly cheapen the price of salt which is now sold at Puttalam at the rate of 2 cents per lb., but at about double that in the Chilaw district and at a still higher price in the Negombo district. This is certainly due to the great extent of transport by Canal, which on the other hand gives little or no

profit to the poor padaboatmen who resort to adulteration with sand to make up their losses. All this will be put a stop to, with the advent of a railway to Puttalam, which will cheapen the price of salt and stop adulteration thereof with sand.

RESIDENT OF PUTTALAM.

PLANTING, GEMMING AND ROADING IN BAMBARABOTUWA.

DEAR SIR,—In reference to the article signed "Critic" in the local "Times" and headed "Gemming in Ceylon," the 860 acres Kondurugalla jungle referred to belonged to one Marikar, and was bought, I think, by Mr. L. Davidson, Messrs. Finlay, Muir & Co.'s late V. A., for something under R30 an acre and subsequently re-sold to Messrs. Finlay, Muir & Co. I am not sure at what price it was bought, or re-sold. The cutting of the road and connecting it with the Ratnapura and Balangoda districts did much anyway to add to its value, but for this, the land was difficult of approach. The road was cut by Messrs. Finlay, Muir & Co., when Mr. Gray was on Hopewell and enabled Messrs. Finlay, Muir & Co.'s, Visiting Agent to ride in at Ratnapura end and out *via* Balangoda. The land now belongs to Messrs. Finlay, Muir & Co. and felling operations are going on apace both there and on Bambera Ellakande, the adjoining land. I should say quite 2,000 acres or more are being felled in this one locality by this firm. I believe watchmen were actually put on to keep off petty gem-diggers and pilfering and contractors engaged on any work on this block are likely to delay finishing off, to enable them to have a good search for gems while so engaged.

It is strange that the old Bungalow sites on these blocks command a view of Hapugastenne Bungalow, and the Hopewell Wellawalamukelana are *all* more or less seen from one another, thus enabling the old Coffee Planters in 1848 to keep up a series of signallings, in troublous times. From S. D's Bungalow at Hopewell, only 12 miles by road (and about four in a direct line) from Balangoda, the Colombo Lighthouse flash is plainly discernible, while on a clear day steamers can be seen—and a view of the sea coast, as far as Hambantotta is obtainable in another direction. This would make an excellent signal post—with an electric light right across the Island,—or a Heliographing station, if occasion arose.—I remain yours,

PET ELEPHANT.

FIBRE AGAIN: A CEYLON FIBRE-PLANT PRAISED.

DEAR SIR,—It is evident that the maxim of being denied honour in one's native country is also shared by our Sansevieria or "bow-string hemp." A correspondent to the "Florida Agriculturist" writes that Sansevieria Zeylanica though introduced into Florida as an ornamental plant, where it has been christened the "trout plant," probably on account of the peculiar spots or markings on the leaves, yields a fibre "of the finest and strongest yet discovered;" and that its cultivation in that country is about to assume the proportions of an important industry. Eighteen months after setting the plant, it is said, the first crop can be cut; but two crops annually will be yielded thereafter, the yield of clean fibre per acre being five tons. The writer in question also hints at the prospect of there being within the next twelve months thousands of acres in Florida, planted with Sansevieria; and that, if recent investigations were not misleading, "there will be no need to go to Klondyke for gold."

That the Sansevieria fibre is of a very fine quality, comparatively easy of extraction and well appreciated in the market, has already been testified to by planters in Ceylon. Yet though the Sansevieria is a jungle plant here, it has not so far proved quite amenable to our methods of cultivating it; or at least its cultivation has not been considered sufficiently remunerative to oust antecedent products. In our jungles the plant is almost invariably met with on rocky soil, a fact which suggests that the principle of affording it deep rich soil is at fault, and moreover that the Sansevieria is a most suitable plant for planting up waste and rocky corners on lowcountry estates, thus excelling the far-famed rhea or ramie which generally requires the richest of soils. The Sansevieria also enjoys total immunity from any disease or insect pest.

It is curious to note that in Dr. Watt's Dictionary of Economic Plants, there are no less than 25 vernacular names quoted for the Sansevieria, which, however, are mainly Asiatic, in Europe the plant is commonly known by the name "sword plant."—Yours truly,

NIYANDA.

[We quote the Florida extract in full in our *Tropical Agriculturist*. The soil we saw in Florida was generally light and of brackish-sand as in the Rajatalawa-Chilaw district.—ED. T.A.]

CEYLON TEA IN AMERICA.

Kandy, Jan. 17.

SIR,—Mr. Mackenzie writing from London on the 24th December commences as follows:—

"I returned home last week and in a more hopeful mood as regards progress in America, than on any previous occasion. Our teas are getting better known and more appreciated every month. He goes on to say that the packet business of a large English firm, which sells, Ceylon and Indian teas in America has doubled and another trebled during the year. He gives encouraging details of the manner in which a Chicago Firm known to be considerable purchasers of tea in the Colombo market, are advertising in the west states that two American Firms are now buying regularly in London and holding stocks of our tea in New York and refers to several English houses who are doing the same, one of the latter in particular doing a very large business and handling no China or Japan bear at all." He concludes as follows:—"The most satisfactory sign of all is the number of small dealers who are everywhere holding our teas now and the number of houses putting up their own packets.

"My report with the accounts will follow in a few days.

"I send you a memo, which you might publish for the benefit of Colombo shippers, showing the difficulties which arise when teas are shipped different from the samples. It comes from one of our best friends.

"I also send some of the indefatigable Larkins communications, they will show you how we get the rejected teas stopped entrance into Canada, also our advertisement in last Canadian Grocer."

CEYLON TEA IN THE CONTINENT OF EUROPE.

Mr. R. V. Webster who received as grant of £500 from the X X X Committee for the purpose of advertising Ceylon tea on the Continent of Europe writes that he has visited the principal towns in Belgium, Holland, North Coast of Germany, Denmark and Sweden, and that he has succeeded in interesting a great many in Ceylon teas

and is sending small shipments forward to each town. The duty in Belgium is 4d per lb. Holland 2½d, Germany 3d, Denmark 4½d, Norway 1s, and Sweden 3d. He has made arrangements with the largest tea importing firm in Stockholm for making known Ceylon tea in Sweden, and also with a Firm of good standing in Norway. He said "I can quite understand the British Commercial Agent giving Russia a wide berth. It has taken two days hard work to get my tea through the Customs, and then I had to pay duty on nearly double the correct weight in this country there is no redress and foreigners are treated with the greatest contempt.

Mr. Webster subsequently visited St. Petersburg, Moscow, Kief Odessa, and nearly every seaport in the Black Sea and writes as follows:—"Large quantities of Ceylon Tea is finding its way to Russia and I am certain there is a great future in this field for our teas which are mostly used for blending with China."

I know of two Firms who each imported last year over a million pounds of Ceylon Tea:—"The imports of Indian Teas into Russia have fallen off during the past few years, while those of Ceylon have very much increased, as they find them better suited for their blends."

Mr. Webster completed his three months tour on the continent by visiting Austria Hungary and Italy and has appointed Agents in many towns who will endeavour to push Ceylon Tea. He will return to Ceylon in the ss. "China" due on the 25th instant,—I am, dear Sir, yours faithfully,
A. PHILIP,

Secy. to the Thirty Committee.

India Tea Association 138 Front Street,

New York, Dec. 7th, 1897.

The main trouble with India and Ceylon teas in the American market is that when teas are sold forward on samples that it is most difficult, if not impossible to make the goods match the sample.

A firm may order from standard sample a couple of hundred chests of tea, when the shipment comes forward this is found to be made up of several "breaks" from one garden, or even from distinct gardens. These lines must differ somewhat under present conditions of manufacture, and, as a consequence, the buyer has a right, and exercises it of rejecting those which are least like the sample. Indeed, he may reject the entire shipment. This may be done in perfect good faith, for, he, in turn, may have sold to his constituents on the original samples, but finds the goods are not suitable for his trade either on account of leaf, or liquor not having been matched.

In the event of such rejection a great deal of cross correspondence ensues. The tea may have been paid for on letter of credit. The merchant rejecting it, has to notify the local agent who, in turn, notifies his principal in Calcutta or Colombo. Bills have then to be drawn on the shipper, and there is a delay of from two to three months before matters are adjusted. Or the tea may have been shipped and the documents drawn against. The bills have to be accepted by the merchant who ordered the tea, purely as a matter of courtesy, and bills drawn against the shipper.

In the case of the shipment being taken over subject to revelation and an allowance made, the same tedious process has to be gone through. The merchant buying on mail samples feels he is running risks as he is not buying on actual samples drawn from the chests as he would do if

the tea was on the spot, or where he a buyer in London, Calcutta or Colombo. The gist of this trouble is that it is apparently impossible to rely upon teas ordered on samples being matched.

This trouble will exist so long as no provision is made for blending teas in the Eastern markets. Until then there is no guarantee that samples will be accurately matched, and the trade is carried on practically upon the local agents' good character and reliance upon his good faith.

In some cases the buyer of a house refuses to buy on samples, and will only go so far as to order teas on approval. Such orders are at the risk of the local agents, and he in turn has to rely upon the Calcutta buyer, following his instructions as to selections of tea. In filling the order the same difficulty occurs in obtaining long lines, and the shipment is composed of several breaks bought at different prices averaging the limit imposed. The buyer here may select the teas which brought the highest price, and the balance on sale in the open market may lose the sipper the entire margin of profit which would have been obtained, had the whole line sold at the average expected.

All in this class of business are of opinion that it would be better in cases where tea cannot be matched absolutely, or where only a portion of an order can be filled to match the standard, that that portion only be shipped, or the order left unexecuted, rather than that buyers here should be subjected to the trouble and annoyance of dealing with teas they do not want, and have not ordered.

WELL DONE MATALE: 1,066 LB. OF
MADE TEA PER ACRE.

SIR,—I last year reported to you a crop of 993 lb. made tea per acre from this estate for 1896. For 1897 I realized from a total bearing acreage of 204½ acres, a crop of 218,290 lb. made tea, equal to a yield of 1,066 lb. made tea per acre. This has been realized without manure and by medium plucking. I manured some 25 acres in October, but no result has shown itself to date. Also I may say that some fields were "off" flushing, having run to leaf owing to my not having been able to prune them, otherwise crop might have been larger.

I believe that several Matale Valley estates can run my figures very close, too.—I am, &c.,

H. STOREY.

Warakamure Estate, Matale, Jan. 12th.

THE BAMBARABOTUWA DISTRICT —
AND CORRECTIONS,

Ratnapura, Jan. 17.

DEAR SIR,—Some errors have crept into your leading article *re* opening of the Bambarabotuwa-Ratnapura districts.

Hopewell estate is 40 miles from Ratnapura: if you go via Balangoda outlet, but only 23 by cart road now being constructed via Hapugastenne it joins in, or branches off at Vewalkettiya.

Government did not give three acres heavy forest for one, but three acres *chena* mixed with bothersome native holdings per acre of jungle.

Hopewell factory is intended to turn out 1,250,000 or 1½ not 2½ million lb.—Yours faithfully,

JAMES GRAY.

[The correspondent who distinctly wrote 2½ million to us, should be metaphorically "hanged." —Ed. T.A.]

COFFEE AND CONSPIRACIES IN BRAZIL.

After a considerable interval we have received an interesting, chatty letter—see page 547—from Mr. A. Scott Blacklaw, so long resident in Brazil, although he began life as a Ceylon planter. His introduction gives us a very graphic account of the curious disturbance in the State of Bahia—dignified with the name of “Revolution” through the persistent way in which the Government police and troops sent against the “rebels” home or stockade, got defeated over and over again. Mr. Blacklaw winds up too with a tragedy in the attempted assassination of the President and actual murder of the Minister at War. But in between comes the practical part of the letter in which our correspondent has to tell us about “coffee” in the great South American State. We should have wished to learn more particularly of the condition and prospects of the Dunmont Company’s properties in which so many leading Ceylon men are interested; but we learn instead the general prospects, and certainly these do not indicate any cessation to the extension of coffee planting in Brazil, cheap though the produce has lately been. If the Brazil authorities really sold their State Railways and established a stable Currency, a new era of prosperity might be expected for their very rich country.

PRODUCE AND PLANTING.

BRAZILIAN RUBBER.—The British Consuls at Para and Manaos give in their official reports some interesting particulars regarding the rubber industry. Mr. Churchill, who is stationed at Para, says, in regard to the question of buying rubber forests, that he gathers from those engaged in the trade that it would be possible to buy forests, and probably whole islands, producing the best rubber, but excessive prices would have to be paid, as rubber is the chief industry at Para, and yields comparatively large profits to the greater part of the population. It is believed that it would be quite impossible to compete successfully with Brazilian and Portuguese forest-owners, who exploit their estates in the most economical manner, and can stand the climate, which is deadly to Northern Europeans. It appears that the trade is practically in the hands of a class of traders called *aviadores*, who establish themselves at various points on the Amazon, and advance food and other requirements to the collectors of rubber, and in exchange they receive all the rubber collected, which they send down the river for sale at Manaos or Para. Through the credit system the *aviador* makes the collectors of rubber permanently in his debt. He is enabled to accomplish this all the more as the rubber districts do not produce any foodstuffs, and all payments for rubber are made in kind. It is said that it is not customary to buy forests, as they are worthless to the owner unless he can get the produce, and he certainly does not get it unless he lives on the spot and acts in the same way as the *aviador*. This would appear simple, but, so far as Europeans are concerned, it appears to be rendered impossible by the climate. There is no doubt that the climate most suitable for rubber is the least suitable for human beings, especially white ones. But given reasonable comforts, and proper food, which it is possible to have on the banks of the Amazon, a Britisher, with proper organisation, might perhaps stand the much-dreaded climate. The best means of working a large rubber business would probably be to employ a large number of *aviadores*, and to make their centre at Manaos.

PLANTING IN BRITISH CENTRAL AFRICA.—Up to the present the exportation of coffee to Europe from the Nyasaland Protectorate has been little more than an

experiment. There was no question about the high quality of the berry there produced; all experts pronounced it to be quite of the old Mocha standard. But before going farther with the venture it was essential to ascertain whether transport charges would not swallow up all profits. The voice of the pessimist uttered that dismal prophecy freely enough, while the doleful Little Englander refused to believe that any good could come out of British Central Africa. Remembering these mournful predictions, it is pleasant to learn that the planters are entirely satisfied with the financial results of their plucky experiment. A greatly extended area has been brought under cultivation, and the time seems not far distant when the Protectorate will become a dangerous rival to Brazil in the European market. The planters also look forward to the time when the Zambesi branch of the Bechuanaland Railway will bring Nyasaland into touch with British South Africa. That is no longer a dream, but, thanks to Mr. Rhodes, on the way to become a realised fact at a comparatively early date. Tea of high quality is also produced in the Protectorate; indeed, so rich is the soil and so propitious the climate that it is very difficult to say what crops could not be cultivated. There is, too, an abundant supply of very cheap labour, and although newcomers are apt to pick up fevers before they become acclimatised, the old Scotch planters and missionaries are said to enjoy excellent health. When the Zambesi branch of the Bechuanaland Railway is completed there seems to be no reason why planters should not supply Mincing lane with both tea and coffee.—*H. and C. Mail*, Dec. 31.

GOW, WILSON & STANTON’S INDIAN AND CEYLON TEA SHARE REPORT.

London, E.C., Dec. 31.

It is only during the last few years that investments in Tea Producing Companies have been extensively made by the public. Until lately, they were looked upon as difficult of sale, an opinion which was certainly correct some years back, but is far from being so at the present time. Shares have lately become so widely distributed that their market-ability has considerably increased.

The past year has been noticeable for its increasing number of comparatively small investments, rather than large amounts; and for the distribution of Tea Shares over a more extensive area.

Tea production was carried on under greater drawbacks than during the past two or three years. In the first place, Exchange ruled at a higher average. This enhanced cost of production, which was further raised by the high price of rice, owing to the recent famine in India; the average price was also somewhat below that of last year, while the earthquake in India has also, either directly or indirectly, affected several Indian Companies.

The average price of all Indian Teas sold in London since commencement of season was 8'99, against 9'13d same period 1896.

The average price of all Ceylon Teas sold in London during 1897 was 7'71, against 8'21d same period 1896.

It may therefore be doubted whether the result of cultivation will be as satisfactory as during the two previous seasons; still many of the best Companies should be making fair profits, although such as have not accumulated a solid reserve, may, and in some instances have to, distribute less in dividend.

The growth in consumption was larger than in production, new markets, as well as the home trade, having shown a substantial advance.

There appears, therefore, no likelihood of immediate over-production, while the fact that India and Ceylon together subscribe some £18,000 per annum for the purpose of fostering the use of their Teas in new markets, is sufficient evidence that Planters are on the alert to prevent actual danger menacing the Industry, through lack of energy or forethought upon their part.

Regarding the question of Exchange, as long as the Indian Ccinage Act remains as at present, Exchange cannot rise much over 1s 4d, while many people who are intimately connected with the subject believe that the rate will be lower during the coming year; the average in 1897 was 1s 15-32d against 1s 2-13-32d in 1896.

Although the strong demand which has taken place in the last few years for Tea Shares caused a considerable rise in their market value, the prospects of a somewhat poor year have lately caused a reduction in quotations of many securities, and the market for the year closes lower. Several Companies were brought out during the year, the general tendency being for private owners to amalgamate different gardens together, and then form the groups into Limited Liability Companies.

Ceylon Dividends.—Ceylon L. & P., a final 7½ per cent Ord., 3 per cent Pref. and a Bonus of 5 per cent on Ord.; Dimbula Valley, 2nd Int., 2½ per cent Ord.; Mayfield, Int. of 3 per cent Pref.

THE DIMBULA TEA ESTIMATE.

The following is a copy of the full return laid on the table at the recent annual meeting of the Dimbula Planters' Association:—
1897—Tea estimate 19,323,510 lb.

	Acres.
Tea in bearing	41,232½
Native	2,826½
Total	45,059
Cultivated, but not tea	416
Total cultivated	45,475
Uncultivated	9,522
Total acreage	52,997
Average yield per net acre 457 lb,	
" " gross	437

TEA AND COFFEE TRUST.

Any one who looks into the dates and periods of the formation of the various financial trust companies cannot but observe how invariably they have been promoted just when prices are at the top of the wave. It may be true to say that this must necessarily be the case inasmuch as investors are forced into subscribing for their Preferred or Deferred Stocks by cheap money. As cheap money also means high prices, the natural consequence is that the directors of the Trust Company either buy in at about the highest average of the year or they unconsciously become the recipients of unmarketable and bad securities.

The last boom in Financial Trust Companies corresponded roughly with the last boom in Argentines. We should like to see, just as a matter of curiosity, how many purchases of Buenos Ayres Great Southern or of Central Argentine Railway Ordinary Stocks were made at prices of 190 and over, and how many were made a few years later, when these quotations had sunk to 95 and 50 respectively. When these railways were up at the former level of value, the Trust Companies were coming out week after week, and had hundreds of thousands of pounds to lay out. When the same Railway Stocks were in the mud the same Trust Companies had neither the funds nor the faith to buy a single thousand Stock.

At the present time a great boon would be bestowed upon investors if a highly reputed Financial Trust Company could be formed for the purchase of tea and coffee shares, thus spreading a million or so of money among the shares both of well-known Indian and Ceylon tea gardens, and also among home trading concerns which sell tea retail and which pay handsome dividends. Sooner or later the far-off cry for a free breakfast-table will make itself heard in Parliament, and the consumption of tea will be increased by 50 per cent within the following three years.

There are many Indian and Ceylon tea shares as well as tea shares in the industrial market over here which can be bought to yield from 5 to 7 per cent upon money invested. If a sum of £10,000 were divided among a score of such companies, no one can say that it would not be far more safely invested than if sunk in any one company. Instead of £10,000 a sum of £3,000,000 could easily be outlaid, and a new company with a capital of £1,000,000 in Three-and-a-Half per cent Debentures, £1,000,000 in Four per cent Preference, and £1,000,000 in Deferred, would receive immediate support.—*Echo*, Dec. 28.

HAPUTALE DISTRICT IN 1897.

WEATHER.—Rainfall about 45 to 50 inches above the usual average!

CROP.—Latter half of the year, bad flushing weather, most estates short of estimates. Coffee crop little or nothing.

LABOUR.—Fairly plentiful.

ROADS.—As there is a great saving of upkeep on the road all below Haldummulla, Government might allow the four miles, say from Kalupahana estate turn-off, to Haputale, to be repaired twice in the year. Once is not sufficient with all the heavy up-traffic it gets now, which it never did before the railway was opened.

GRIEVANCES.—No Telegraph station yet at Haldummulla, no siding at Idulgashena gap, where there should have been a Railway Station, according to original estimates. The line was made level on this spot for a station, and everything is ready for it. Natives would buy up the Government land on both sides the line very readily for boutiques. But nothing is done

PLANTING NOTES.

AVOIDING A THUNDERSTORM.—On the approach of a thunderstorm French peasants often make up a very smoky fire, says *Industries and Iron*, in the belief that safety from lightning is thus assured. By some this is deemed a superstition, but Schuster shows that the custom is based on reason, inasmuch as the smoke acts as a good conductor for carrying away the electricity slowly and safely. He points out that in 1,000 cases of damage by lightning 63 churches and 85 mills have been struck, while the number of factory chimneys has only been 03.

PRICES OF PLUMBAGO.—A merchant calls attention to a remark in our review of the year's exports which ran as follows:—

The exports of Plumbago have been fairly satisfactory and so have prices; but higher prices have ruled before now, and if there be a reversion to them, there is no reason to suppose that we shall not be able to send away more than the 357,257 cwt. we did last year.

Our correspondent adds:—"I don't think prices ever came within 25 per cent of those ruling as last year closed and this year opened." We stand corrected: we certainly thought that in the "sixties" or "seventies" prices were higher than in 1897; but we had not time to refer. We are glad to note maximum prices for our one mineral of commercial importance, and feel sure that they must lead to a development of the mining industry. Indeed Capt. Tregay's "mission" is primarily connected with plumbago. Would that the Government Geologist from India made his appearance and began the Survey. Although no one has suggested it that we have seen, it is just possible, we suppose, that plumbago veins may run through the country North of Kurunegala, about which we can get no encouragement from a planting or agricultural point of view.

THE LAST QUARTERLY SALES OF CINNAMON.

The particulars we lately published of the quarterly sales of Ceylon Cinnamon held in London on 29th November, exhibit a very large and varied catalogue. The quantity brought to the hammer was no less than 3,690 bales, against 1,298 at the previous quarterly sale, and against 1,400 bales at the corresponding sale of 1896. Notwithstanding that more than double the quantity which we offered at previous sales was catalogued, and perhaps the largest quantity ever brought forward at one sale, the competition was brisk, and about three-fourths of the offerings were disposed of. Naturally, the prices were rather irregular, as buyers would hold back to see whether the demand was at all commensurate with the immense supply; but the prices at which most of the lots were cleared, make the disposal of 2,350 bales a very satisfactory feature of the sale. At most there was a drop of a penny a lb. for ordinary sorts, which had the drawback, in the eyes of the London monopolists, of being "unworked"—that is, in the opinion of local shippers, of not having contributed to the exorbitant charges of Warehousemen for mnding and re-doing (badly) the baling and sorting which had been already well done here; while the better sorts of cinnamon and those which had been "worked" fetched higher prices than in August. Indeed, the competition for the best brands was keener than it had been for almost a score of years, and quite recalled "old times." Thus A. S. G. P. (Golua Pokuna), F. S. W. S. and F. S. K. (Wester Seaton and Kimbulapitiya, whose industrious head Frederick Schrader, joined the majority last year) and J. D. S. R. (Kajepakse Mudaliyar's brand) were well competed for and held their own at prices ranging from 1s 3d to 1s 7d for Firsts, and 11d to 1s 3d for Fourths; but the "record" was marked when Golua Pokuna fetched 2s 4d for a lot of six bales of its Firsts. Of course, this was a fancy price, and may not again be realized for years; but the competition which led to such a price shows, both that the old mark still heads the list under Mr. Gerald Nicholas's careful supervision, and that cinnamon is attracting more attention than it has done for years. "Unworked" cinnamon, which is not graded so carefully, realised from 7d. up to 1s. 1d. per lb., which, we fancy, is scarcely less than the price which "worked" cinnamon of the same class fetched. Anyway, of 2,500 bales of "unworked," including large quantities of the De Soyza marks, 1,800 bales were sold at auction.

Altogether, the results of the last sales justify our confidence in the future of the Spice, as expressed in our Review of last year's Exports; and if too much is not thrown on the market at a time, the demand promises to ensure a maintenance of the prices which have ruled for the last three or four years, and given satisfaction to proprietors.

The following is the Report of a leading Firm in the Spice trade on the last Sales:—

London, Dec. 2nd, 1897.

At the closing auctions of this year, held on 29th November, the large supply of 3,690 Bales, Ceylon offered, against 1,289 Bales in the August sales, and 1,400 Bales at this period last year. Notwithstanding the large supply, there was a good demand resulting in about 2,350 bales being cleared. Prices, however, ruled irregular, but on the whole Ordinary and Fair sorts must be quoted about 1d per lb lower, while

the upper grades of fine and superior "worked" well-known brands were well competed for at advanced prices, some of the finest realising fancy prices far above the regular values. These extreme prices were entirely due to the spirited competition of two of the principal buyers to secure the fine lots, such as A.S.G.P., F.S.W.S., F.S.K., and J.D.S.R.; and they cannot be looked upon as any guide to values at the next sales. "Worked" sold, First sort, fair to good 11d to 1s; fine to superior 1s 3d to 1s 7d with one lot at 2s 4d; second, medium to fair, 10d to 11d; fine to superior 1s 2d to 1s 7d; thirds ordinary to good 9d to 10½d; fine to superior 1s to 1s 5d; Fourths ordinary to fair 8 3d to 9½d; fine to superior 11d to 1s 3d per lb. Of the 2,550 Bales "unworked" cinnamon offered, some 1,800 Bales were cleared at prices ranging from 7d up to 1s 1d per lb, for ordinary to good.

Chips &c. of 1,030 bags on sale, about 250 sold, ordinary to good 3d to 3½d; Quillings &c. 9d to 11½d per lb.

Stocks of Ceylon 4,384 Bales' against, in 1896—2,100 Bales, 1895—5,679; 1894—4,087.

The next Sales are fixed for 28th February 1898: FORBES, FORBES & Co., Limited.

THE CEYLON "THIRTY" (TEA) COMMITTEE.

Minutes of proceedings of a meeting of the "Thirty Committee" held at Kandy on Saturday the 15th day of January 1898 at half-past seven o'clock (7-30 a.m.) in the morning. Present:—Hon. Mr. J. N. Campbell (Chairman), Messrs. A. Philip (Secretary), W. Henry Figg, James G. E. Ryan, Edward Rosling, A. Melville White, Edgar Turner, J. H. Starey, Joseph Fraser, F. G. A. Lane, R. A. Galton, Oliver Collett and Gordon Pyper. The notice calling the meeting was read. The minutes of proceedings of a meeting of the "Thirty Committee" held at Kandy on Saturday, the 13th day of November, 1897, were submitted for confirmation. Resolved:—"That they be and they hereby are confirmed."

FINANCES.—Submitted letter from the Treasurer of the Colony.

Read letters from the Manager National Bank of India Limited.

MINUTES.—Read letter from Government acknowledging receipt of copy of the minutes of proceedings of a meeting of the "Thirty Committee" held at Kandy on the 11th September and confirmed at a meeting held on the 13th November 1897.

GOVERNOR IN EXECUTIVE COUNCIL.—Read letter from Government intimating that the Governor has been pleased with the advice of the Executive Council to approve of the proposed expenditure of £200 sterling in advertising Ceylon tea in Austria and Hungary.

REPRESENTATIVE IN AMERICA.—Read letter from Mr. Wm. Mackenzie to the Secretary dated New York 7th November, 1897. Read letters from Mr. Wm. Mackenzie dated New York 1st November, 2nd November, 9th November, 16th November, 19th November, 1st December, 24th December to Mr. Campbell with enclosures. Resolved (I):—"That the memo forwarded by Mr. Mackenzie for the benefit of Colombo shippers showing the difficulties which arise when teas are shipped different from the samples be published." Resolved (II):—"That the thanks of the 'Thirty Committee' be conveyed to Mr. Blechynden for his successful efforts in connection with the American legislation regarding the 'sieve' test for teas imported into the United States of America." Resolved (III):—"That the credit for £4,000 sterling favouring Mr. Wm. Mackenzie and wired to London the 8th January 1898 be confirmed." Resolved (IV):—"That the question of placing a certain amount of the 'Tea Fund' in fixed deposit be left for consideration in the hands of the Chairman and Secretary." Resolved (V):—"That an approximate statement of the amount at credit of the Fund and of the appropriations voted by the 'Thirty Committee' be placed on the table at the meetings of the Committee with a view to show the funds available.

Read letter from Mr. J. D. Quinn. Resolved:—"That the Secretary's letter in acknowledgement be confirmed and that Mr. Guinn be referred to Mr. Wm. Mackenzie."

Read letter from Mr. F. A. Pappé. Resolved:—"That the Secretary's letter in acknowledgement be confirmed."

Read letter from Mr. Fred. W. Bois. Read letter from the Ceylon Association in London forwarding copy of correspondence with the Secretary of Her Majesty's Customs in regard to tea rejected by the American Customs as to which Mr. Mackenzie sent advice. Resolved:—"That the letter be published."

CEYLON TEA IN RUSSIA.—Read letter from Mr. M. Rogivue. Resolved:—"That the letter be published." Read letter from Messrs. Peek Brothers and Winch Limited. Read letter from Mr. J. M. Maitland Kirwan. Read letter from Messrs. A. F. Vagð & Co. Resolved:—"That the Secretary's letter in acknowledgement be confirmed and that in further reply it be stated that the Committee will be glad to receive any information or letters from them for guidance."

CEYLON TEA IN THE CONTINENT OF EUROPE.—Read letters from Mr. R. V. Webster dated Stockholm, Sweden 24th October, St. Petersburg, 31st October, Moscow 2nd November, Buda-Pesth, Hungaria 12th December, Syracuse, Sicily, 24th December 1897, reporting on the work done by him in advertising Ceylon tea on the Continent of Europe in terms of the minute and resolution passed by the Thirty Committee at a meeting held on the 16th of January 1897.

CEYLON TEA IN AUSTRIA AND HUNGARY.—Read letters from Mr. G. A. Marinitsch, Colombo with reference to the free distribution of Ceylon tea through the press or otherwise under the resolution of the Committee passed on the 13th November 1897.—Resolved:—"That Mr. Marinitsch be asked to confer with Messrs. Renton and Ryan in whose hands the arrangement of the whole matter is left by the Committee. Read letter from the Imperial and Royal Austro-Hungarian Consul at Colombo stating with reference to the contemplated presentation of Ceylon tea to His Imperial and Royal Majesty the Emperor Franz Josef on the occasion of the Jubilee of His Reign that the intention will be conveyed to the Lord High Steward of His Imperial and Royal Household.

Read letters from Messrs. J. H. Renton and J. P. Ryan.

Read letters from the Ceylon Tea Company Limited, Colombo, transmitting invoice for a 1,000 lb Ceylon tea in 800 one ounce packets shipped to the Anglo-Colonial Import Association Buda-Pesth, Hungary in terms of minute and resolutions passed by the Committee on the 10th July 1897. Resolved:—"That the approval of the Governor in Executive Council be obtained to this appropriation.

Read letter from the Agents Ceylon Tea Company, Limited, Colombo with Invoice for 500 lb. Ceylon Tea delivered to Messrs. Darley Butler & Co., for distribution in Austria and Hungary on behalf of a correspondent in Vienna under minute and Resolution passed by the Committee on the 13th March, 1897.

Read letters from Messrs. Cooper Cooper and Co., Limited, London.

CEYLON TEA IN BELGIUM:—Read letter from Messrs. Cooper Cooper and Company Limited on the subject of pushing and advertising Ceylon Tea in Belgium. Resolved:—"That £200 sterling be granted to Messrs. Cooper Cooper and Company, Limited for advertising Ceylon Tea in Belgium. (2) That Messrs. Cooper Cooper and Company, Limited be requested to furnish the Committee with a formal report of progress for publication from time to time. (3) That Messrs. Cooper Cooper and Company, Limited be asked to consider the grant made on condition that Ceylon Teas only are advertised and pushed. (4) That the sanction of the Governor in Executive Council be obtained to the above mentioned appropriation."

CEYLON TEA IN SWEDEN:—Read letters from Messrs. Cooper Cooper and Company, Limited in reference to advertising Ceylon Tea in Sweden. Resolved:—"That a sum of £40 sterling be granted to Messrs. Cooper Cooper and Company, Limited, for adver-

tising Ceylon Tea in Sweden and that they be informed that in future application should be made to the Thirty Committee and sanction obtained before expenditure has been incurred by Messrs. Cooper, Cooper and Company, Limited on behalf of the Committee (2) that the sanction of the Governor in Executive Council be obtained to this appropriation.

CEYLON TEA IN FRANCE AND SWITZERLAND.—Read letters from Messrs. Peek Brothers and Winch, Limited on the subject of pushing Ceylon Tea in France and Switzerland. Resolved that the Chairman do communicate with the Agent at Colombo of Messrs. Peek Brothers and Winch, Limited on the subject and that meantime consideration of the matter be deferred.

CEYLON TEA IN NORWAY.—Read letter forwarding Report from Mr. C. Floor on the progress made in pushing Ceylon Tea in Norway. Resolved that the Chairman be asked to deal with the matter.

CEYLON TEA IN SOUTH AFRICA.—Read letter from Messrs. Murdoch and Branwell asking for a grant for pushing and advertising Ceylon Tea in the South African Republic. Resolved that the Thirty Committee do grant to Messrs. Murdoch and Branwell, a sum of £200 sterling for the purpose of advertising Ceylon Tea in South Africa on condition that they or their constituents spend a further sum of £400 sterling in such advertising of Ceylon Tea in South Africa (2) that reports and accounts be submitted from time to time for the information of the Thirty Committee.

CEYLON TEA IN BURMA.—Read letter from Mr. C. G. Jansz. Resolved that the Committee regrets that they are unable to entertain the application. The Thirty Committee then adjourned. A. PHILIP.

Secretary to the Thirty Committee

(QUININE) CINCHONA BARK.

Messrs. S. Figgis & Co.'s Review, for the year 1897, is worthy of attention:—

This year has been eventful in the great rise in value compared with 1896. The excessive shipments from Java appear to have reached their maximum, after the very rapid growth of the previous fifteen years, and the same causes as have led to the almost exhaustion of many Cinchona plantations in Ceylon, whence we received as much as 12 million lb. 10 years ago, against 1 million this year, induce many to think that Java will decrease her production for some years. Whatever the causes may be, the Java shipments are only 8½ million lb. against 10½ million lb. last year. Ceylon has not increased her supply, nor India to any extent, and South America has not recommenced, and Bolivia sent but trifles (mostly for Druggists' purposes.) Coupled with a falling off of 15 per cent. in supply of bark as compared with an average of the last five years, there has been an extraordinary demand for quinine, all the factories of the world having been fully occupied during 1897 and the old stocks of former years' speculation nearly exhausted in America, and reduced by one-half in Europe. Doubtless the unprecedented low price of quinine last February induced many dealers all over the world to buy freely, but today's stocks of quinine and of bark are very moderate, and probably not two-thirds of stocks at same period of the last ten years. We are of opinion that the very low price for bark, 3d (2.12 cent.) per unit, was totally unremunerative to growers, and that in consequence many estates have rooted up the trees; Succirubra plantations we know have largely decreased, and the active demand and enormous price paid for this Bark and for Cinchonidine, 8½d per ounce recently, is the natural consequence. It must be remembered that it takes 7 or 8 years for newly planted trees to yield appreciably. Therefore we expect that, unless we have a renewal of the very large shipments from Java and elsewhere, we may see a higher range of prices for some years. Our tables of figures of supply, price, contents, &c., shew the enormous quantity that has gone into consumption, and if this has been so with excessive old stocks of quinine, we see no valid

reason to expect a less consumption in future. Indeed, the so-called "opening up" of China, Corea and the East must tend to enlarge the demand, and America has steadily advanced her requirements of late years.

PROPOSED ALTERATION OF COFFEE SALE RULES.

A largely attended meeting of the coffee trade was held last week at the London Commercial Sale Rooms, Mincing Lane, E.C., "to consider the advisability of altering the rule governing the conditions as to size and sale of lots offered in public sale." Mr. Melville Woodhouse was voted to the chair, and said the meeting had been called together to see whether some means could not be devised for facilitating and expediting the sale of coffee. If it could be done without in any way interfering with business they would all be glad, but personally he did not see how it could be done. He would, however, venture to make one suggestion, viz., that they should endeavour to be a little more punctual in the coffee trade.

Mr. G. W. Rouse said he received the following letter, which explained why the meeting had been called:—"To the committee of the coffee trade.—Gentlemen, we, the undersigned firms, have come to the conclusion that the regulations now observed in public sales no longer meet present requirements, and that they prevent an important and large section of the trade from attending to their business properly. It is a fact that the sale of the considerable quantity of small lots absorbs an abnormally long time. Single bags are continually put in at 20s, 30s, and 40s under their value, and it often takes longer to sell a single bag than piles of 500 bags. Sales are consequently dragged out, and the disposal of important quantities of coffee and the proper working of those sold are prevented through want of time. Besides such a tedious working is demoralising to those interested in important parcels, and not worthy of a great market. We therefore think it would be advisable to dispose of all lots of less than fifteen bags after the larger quantities have been sold, in fact, to bring them under the category of the so-called 'odd lots,' all quantities of less than fifteen bags, irrespective of quality and condition, to be considered odd lots. This arrangement would not inflict hardship on anybody—in fact, it would, we believe, have the opposite effect. It would enable importers to make the desired progress with the important part of their consignments, which is now continually interfered with; it would enable the larger buyers to attend the public sales personally and to work their purchases as required, thus indirectly benefiting importers; and it would not make greater claims on those interested in the purchase of small lots, and on the selling and buying brokers. We may add that the tea trade have successfully adopted a similar regulation. We recommend these our proposals to your careful and prompt attention. (Signed) Lansburg & Co., R. Wales (Moffatt & Co., Khun & Co., C. Buck & Co., E. Schluter & Co., F. Huth & Co., Mr. R. Meyer & Co., Krauss and Graeff." Continuing, Mr. Rouse said that, according

to the invitation in the letter, the committee which consisted of buying and selling brokers, was called together, and they unanimously came to the conclusion that the question bristled with momentous difficulties to the importers, and especially those who shipped fine coffees, and also to the home trade. Accordingly the committee came to the conclusion that they did not see their way to recommend any alteration in the present system. They felt certain that their friends who proposed the change did not mean to do any injustice to the importers, and did not contemplate that their suggestion would have that effect. The committee, therefore, acting on the saying that "in a multitude of counsellors there is wisdom," had thought it better to call a meeting of the entire trade, so that the whole question might be discussed and definitely settled.

Mr. Schwartz (F. Huth & Co.), in proposing a resolution for the adoption of the change suggested in the letter, said that he and his friends wished to do the best for the market as a whole. The principal points of complaint and the remedies proposed had been embodied in the letter, and he hoped the trade would agree to the proposals they put forward. During the last few years, particularly since their trade with Columbia had developed, an enormous quantity of small lots had been put upon the market, and it had been felt by important sections of the trade that the sale of those small lots absorbed too much of their time, and made it impossible to conduct their business properly. He did not mean to argue that no attention should be paid to these small lots—on the contrary all due care should be paid them, but the large quantities should have the same chance as the small lots, and that was not the case at present. Nobody could dispute that it took longer to dispose of twenty lots of two or three bags each, than it did to dispose of a hundred large parcels. The alterations proposed would, he believed, get over the evil, and benefit all sections of the trade. It was the duty of every trade to arrange their methods of business so that no harm should be imposed on anybody, and that he believed would be effected if the suggestion made were carried out. It could not possibly interfere with anybody if small lots were to be sold afterwards, and under such an arrangement he considered the importers should benefit equally with the brokers.

Mr. Lansberg said that before any discussion took place he would like to suggest that a small committee be appointed to deal with the matter, and report to another meeting. It was obvious that there were many differences of opinion on the question, which could not very well be dealt with at a large meeting. Let a committee be appointed to discuss the pros and cons of the matter, and then perhaps they might be able to recommend an arrangement which might suit the trade as a whole.

Mr. R. Wales said that, as the meeting had been called to ventilate the question, he thought it would be advisable to get the views of some members of the trade before any resolution was proposed. If that were done they might be able to come to a solution of the difficulty which would be satisfactorily all round.

Mr. W. J. Thompson thought there were very grave difficulties in the way of making the alteration, as it would practically relegate the finest coffee into the odd lots.

Mr. Davis said he would move the following resolution:—"That this meeting is of opinion that the suggested change in the odd lots rule is not desirable." He said he had taken the trouble to glance at last spring's catalogue, and if the suggested rule had been in force at least 80 per cent of the boldest size East Indian coffees, and 90 per cent of the peaberrys would have been relegated to the odd lots. Could anybody conceive a more manifest injustice to the importers than that—that the very finest parcels of coffee that came to this country should be treated as odd lots? He did not believe for an instant that

the room would tolerate such a proposal. The existing rule had worked to the general satisfaction of the trade, and had stood the test of many years' practical experience, and had proved a satisfactory solution of a difficult problem. It was quite possible it was not a perfect plan, but it had worked pretty well, and he thought the room had better let well alone. (Hear, hear.) He did not believe that the room would permit such a wanton act of injustice to the importers for the purpose of studying the convenience of a small section of the trade. In his opinion the fewer rules they had the better, and if rules were to be respected they must be framed in a generous spirit and found upon the goodwill of the whole trade.

Mr. Ivey seconded the resolution.

Mr. A. Devitt said, he was sure Mr. Schwartz had brought forward his proposals in the belief that they would curtail the waste of time which occurred in the coffee room sales, and which was to be deplored. If the sales were exhausting to buyer and seller, the exhaustion to the unfortunate auctioneer was even greater. Some of them had done what they could to hasten the sales, but even now some took such a time as was a disgrace and a discredit to the trade. He himself had sat in the box when a very small catalogue had taken three-quarters of an hour or fifty minutes, and a great deal of the waste of time arose from buyers of small and cheap lots not bidding up in a fair and proper way. They had coffee put up which was often started at 50 per cent less than it ultimately reached. But he did not think Mr. Schwartz's proposition would be acceptable to any of them who had to sell fine coffee, or coffee which came in small lots. Take Jamaica coffee—did the resolution include the eight, ten, and twelve barrel lots of Jamaica? Also, did it include East India in cases? Because, if they came to analyse the sales it would be seen that the rules, if altered, would bring about an extraordinary state of things. No doubt the idea was put forward with the best of intentions, but he did not think it would work, and not one of the importers would agree to it. As far as he was concerned, and his merchants, they could not agree.

Mr. Graeff proposed the following amendment to Mr. Davis's resolution:—"That all East India and Ceylon be excluded from the present odd-lots rule, with the exception of triage, blacks, brown, and cherry pickings." He said he believed that if his proposition were agreed to, the difficulty they all deplored would be overcome. They quite understood that importers did not want small lots of fine coffee to be sold as odd lots, and he believed it was the general opinion of the trade that they should not be so treated. (Hear, hear.)

Mr. Lansberg seconded the amendment.

Mr. Wales said he would like to see the question relegated to a small committee, who might bring up an official report, which would act as a guide to the room at a future meeting, as to whether anything, and if so what, could be done to remedy the present state of thing.

Mr. Asser also supported this view, and said he believed a representative committee might be able to devise some means for remedying the evil which would be satisfactory to everybody.

Mr. Davis said he would rather that the meeting voted one way or the other, for if his resolution was carried no committee would be necessary.

The Chairman put the amendment to the meeting, and it was negatived by thirty-eight votes to twenty-one; and Mr. Davis's resolution was carried as a substantive resolution by fifty-four votes to thirteen.

A vote of thanks to Mr. Woodhouse for presiding concluded the proceedings.—*H. & C. Mail*, Dec. 31.

THE ALLEGED FAILURE OF STRAITS COFFEE.—The heavy fall in the price of Liberian Coffee has aroused widespread alarm in the Native Straits. It is alleged that coffee-growing will not now pay there except under exceptional conditions.—*Straits paper*.

MATALE EAST DISTRICT 1897.

WEATHER.—The rainfall has been about 13 inches over the average of 20 years, well distributed throughout, and free from damaging storms with the exception of a few showers in November. The south-west was milder than usual, August and September perhaps being an exception. The north-east till December was fairly favourable.

CROP, excluding estates that are manuring, the yield generally speaking, is behind that of last year off the old area, mainly caused by more selective plucking, and three poor flushing months in the latter half of the year.

LABOUR.—Almost without exception ample for all requirements though with a tendency to a considerable increase in scalled coast advances.

TRANSPORT.—More difficulty has been experienced under this heading than in any previous year of my experience of 26 years almost entirely caused by the deplorable state the roads have got into.

ROADS.—Worse than I have ever known them and this time it has taken to get damaged bridges repaired on the Elkaduwa and Madulkella roads is a crying scandal.

RICE.—Rice throughout the whole year has been costly entailing heavy loss to estates issuing at R4 per bushel. Coolies have also suffered from the high cost of other supplies.

GRIEVANCES.—Bad roads, and an Indian tinkered, and artificial exchange.

PLANTING NTOES.

LADY-BIRDS.—We learn from the *Friend of India* that in connection with the introduction of lady-birds, into India, to combat coffee scale pests, especially green bug, and for which the Madras Government has promised to pay half the cost, the United Planters' Association of South India have voted R2,000, the Lower Pulneys Association have promised R4,000, and the Wynaad Association, probably amongst others, re inviting their members to subscribe.

PINE APPLES.—A prominent importer of pine-apples stated a day or two ago—says the latest *Journal of Horticulture*—that it was probably safe to say that upon an average there are 10,000 pines imported into London every week throughout the year. They are coming now in enormous quantities from the Azores, which seem to have given up growing oranges and have taken to this new cultivation, for which their soil and climate seem to be admirably adapted. Pines are still too dear to be a popular luxury. The average wholesale price is said to be 3s and the retail buyer has to give 4s 6d or 5s for a good pine this Christmas. But the growing of these is rapidly extending, and there is every probability that the price will go down.

THE TIMBER TRADE.—The "Orotava," which arrived in Colombo from Australia lately brought a shipment of Jarrah the well-known West Australian ironwood, for this port. Among the samples, which arrived by the "Orotava," was one for the Public Works Department, and a report on the timber will be submitted by Mr. Davies, Factory Engineer. A special virtue of the timber consists in its immunity from the ravages of the *Teredo*, a worm which exists in salt water and which destroys more wood in its time perhaps than any other insect in existence. A representative of one of our morning contemporaries found Mr. Bostock a great believer in the potentialities of the Jarrah—as was also his predecessor Mr. Kyle. We have in hand an interesting paper about our local hard woods.

BRITISH NORTH BORNEO.

(Herald, January 1.)

It will be news to most people that Ceara ruhher trees are indigenous to Sandakan. A tree in large bearing of seeds is to be seen any day on the Cemetery Road. As however the yield in Comparison with *Hevea* is so small it has not yet attracted the attention of intending rubber planters.

We have received a communication from a London firm stating that a specimen of pineapple fibre extracted locally is pronounced to be of very good quality and likely to meet with a large demand if shipped in sufficient quantities.

Mr. H. N. Ridley left Sandakan for Singapore on the 21st December. During his stay here he was able to make some interesting observations botanical and otherwise.

Continued wet weather has much interfered with cutting hemp and rhea which, of course, require to be dried before packing. Decorticators and baling presses are being shipped from home for the Suan Lambah Plantation.

KUDAT NOTES.

The visits of the Hon. C. H. Strutt, M.P., and Count Geloos d'Elsoo bring us again in connection with Europe. Both these gentlemen are looking very well and appear well satisfied with the present tobacco crop of the New London Borneo Tobacco Company, Limited.

Coffee prospects in Marudu Bay are excellent, and a large crop is anticipated.

The tobacco crop in 1898 will be large, and of very good quality. The Dusuns, this season, have been earning up to 60 cents per diem, at picking and tringing ripe leaves.

 IVORY AND RUBBER IN THE CONGO STATE.

Writing from St. Paul de Loanda, British Consul W. Clayton Pickersgill says there are only two products of the Upper Congo, as far as its resources are known at present, which are valuable enough to pay the cost of transport. These are ivory and india-rubber, both of them, unfortunately, limited in quantity and slow of growth. It is a mistake, however, to regard the exhaustion of either as inevitable. Of the forty tons, more or less, of ivory now being shipped from the Congou monthly, very little is fresh. Comparatively few elephants are being killed, and it lies within the power of the commissaries of districts to declare hunting illegal whenever they have reason to believe that the animals are in danger of being exterminated. No law, of course, can entirely control the native in the wilds, but the State is feared enough to make prohibition serve the purpose desired, and tusks may some day become an article of regulated supply like Kimberley diamonds. In the meantime, there is sufficient indiarubber in the forest of the Haut Congo to yield rich harvests for many a year, even at a much greater rate of exportation than the present, which has attained an average of 100 tons a month. And nothing could possibly repay cultivation better. Ivory may be imitated, but caoutchouc remains indispensable, the one tropical commodity of which the consumption is ever on the increase, while the sources of supply are diminishing. The preservation of the climbing plants from which the elastic juice is obtained, and the introduction of trees containing it in greater quantities, is, therefore, a labour of forethought to which too much attention cannot possibly be given. Already something has been done in this direction by a few officers of superior intelligence, but others have caused wide stretches of forest to be stripped of wealth with little regard for the needs of the future.

—Chamber of Commerce Journal.

PLANTING NOTES.

CEYLON TEA AND EXCHANGE IN 1897.—We direct attention to Messrs. Gow, Wilson & Stanton's Tea Share Report reproduced elsewhere. Written on the last day of the year, it takes the form of a review and we learn that the average for Ceylon teas sold in London in 1897 was 7.71d against 8.21d in 1896; while the average of exchange last year was 1s 3 15-32d against 1s 2 13-32d in 1896—or 11-16d adverse to last year. Both facts tell greatly against profits. Let us hope 1898 may do better in prices if not in exchange.

THE ZANZIBAR CLOVE-CROP.—Advices from Zanzibar state that all plantation-owners in Pemba report a very poor crop of cloves this year. Pemba will probably never again equal the big crops of former years. Many of the trees are getting old and woody, and only have a little foliage at the top, although, if they had been properly pruned, they might now have been in their prime. As it is, some of the shambas present the aspect of forests rather than plantations, and the trees are being used for timber. A very fine sample of Penang cloves recently received from London has been the subject of much interest both in Zanzibar and Pemba. This sample was specially selected to show what good cloves should be like when properly prepared for market. Several experiments have since been made with the object of ascertaining whether it is possible to obtain such good results in Zanzibar. Apparently it is not enough to bestow attention upon the drying only. It is necessary that the buds when they ripen should be picked singly, not in bunches, as is usual in Zanzibar.—*Chemist and Druggist*.

INDIAN AND CEYLON TEA COMPANIES.—From a review in the *Financial Times* of 4th Jan. we quote as follows:—

The total output of tea for the period is estimated for India at 151 million pounds, as against 149 millions in the previous season, while the Ceylon output is calculated at 117 million pounds, as against 108 millions, the advance in both cases being comparatively small, but especially in that of India. As regards quality, that of the Indian crop, speaking generally, was only fair, in some districts the quality being not quite up to that of the 1896 season, while the Ceylon product was about equal to the average. A most encouraging feature of the year is the large increase in consumption, which has more than kept pace with the growth of the output, so that there can be no immediate fear of over-production. The efforts made by planters to extend the consumption of tea, for which purpose they subscribe some £18,000 annually, have met with great success. Continued progress has been made in North America, which bids fair to become soon one of the most important markets. Australia continues to increase its consumption, and the market in Russia and Continental Europe generally is steadily improving. The amalgamation of small concerns into one undertaking made further progress last year. Fifteen new Ceylon companies were formed chiefly for this purpose, and there were several reconstructions with the same object, as well as further issues of capital for extension by one or two of the older companies. It may be noted here that there is a general tendency on the part of private owners to amalgamate gardens into groups, and then to form these groups into limited companies, and there can be no question that the result generally is economy in working. With reference to the probable result to the Indian Companies of last year's working, it may be doubted whether on the whole it will be quite so satisfactory as in the two previous periods.

WHAT TO DO ABOUT CACAO? A HARD NUT TO CRACK.

We give prominence to the following statement of his experience, his fears and expectations by a well-known cacao planter; and we would wish to have the other side presented to us by one of the fortunate ones whose plantations are still free of any pest, or at any rate of any marked attack. At the same time, there can be no doubt of the strictures in the following paper being justly directed in regard to the Government; for, it is clear that there is room in Ceylon plantations of all kinds, for careful scientific investigation even beyond that of the Fungologist or Cryptogamist whom our authorities failed lately to provide for Cacao. What is said about the freedom on certain estates of the Forastero cacao from trouble, can only point to qualities of the soil present in one case and absent in the other. To discover these must be the work of the Chemical Analyst. In fact, we shall never be able to deal with the many questions (and troubles) which turn up in respect of the cultivation of our staple product in the lowcountry as well as on the hills, until an Analytical Chemist and Cryptogamist as well as the Honorary Entomologist, are added to the Staff of, or made available for, the Director of our Botanic Gardens.

(Communicated by a Cacao Planter.)

THOSE who have faith in cacao as a product which "has come to stay," base their belief pretty much on the understanding that the hardier varieties can resist the disease. I hope this is so. The havoc which has been wrought on some estates, where principally the red sorts obtained, is sickening enough, and of late, since the dry weather set in, the deaths have been so numerous, as to greatly exceed anything we have before seen. I don't know how wide the zone may be that has been stricken in this way, but you hear of it in Matale, Kurunegala, Wattagama, and the Kandyside. Well-cared-for estates, that have had every attention, suffer as much as Chetties' gardens, if not more. Cacao under shade—thick or light—is equally ravished, and trees in the open, if perhaps they suffer less, die off here and there, and weakens one's belief, that these conditions of cultivation have aught to do with the pest. If one could be but assured that the hardier varieties were disease-proof, to follow the advice to "go on supplying" with those sorts would be cheery work; for there would be hope in it; but the horrid thought will obtrude itself, that as some of the Forastero have gone already, others may follow. It has been suggested to me that perhaps there may be some deficiency in the soil—such as lime—which is favourable to the disease, and that if the missing element were supplied, the trees would have a healthier life, and be better able to resist. Perhaps some one may have tried lime and be able to speak as to its effects? Soils which were rich in manganese carried the vines successfully, while *phythocera* was rioting where it was deficient, and it is possible that an added element to the soil might do a great work. Whatever may be said as to the duration of cacao, it is pretty clear that at present they are the older trees which are dying out. Not that I have not seen young trees three and four years old succumb; but it is more exceptional.

How useful it would have been if at this time there had been an Agricultural Department to refer to, and from which really good scientific

advice might have been sought; and it cannot but strike the intelligent taxpayer as an extraordinary anomaly that the Colony—the first Crown Colony too—which depends for its revenue on agricultural sources, should be so far behind the world as to leave things to haphazard. In a case like the cacao disease, the planter who sees his estate dying out before his eyes, is not always in a position to launch out in experiments; he sees something very like disaster before him, and even if he gets his supplies to come on and do well, he has years of outlay lying ahead of him, and to conserve his capital is his wisest policy. We have, of course, the enterprising example at Matale, where a private planter imports at his own expense, and without much trouble in finding him either, a thoroughly trained Scientist to investigate, and on the other side the island's Government with all its resources, reporting that such a man could not be had. What incapacity! However, the question is, what is best to be done to replace the ravished cacao fields? Although I feel timorous to some extent, and put out my new plants with my heart at my mouth and a prayer on my lips, still I too would vote for "supplies" as the best thing I know to do. Supplementing with another product, tea, coconuts, or what you like. If the worst comes to the worst, there is this insurance policy behind as it were,—that in the event of a burst-up of cacao, although money may have been lost, some time will have been saved. Under any circumstances, the Ceylon cacao planter who has suffered or is suffering, has a hard nut to crack, and those who report their gardens free of the pest, must have uneasy feelings, and an undefined dread of the future. A few years ago to possess a cacao garden was to be a favourite of the gods, and in for a good thing: now that the shadow of eclipse is over us, let us remember those good times and live in hope.

FACTORY EXTENSIONS AND WORK.

A few weeks ago we gave an account of the work Messrs. Brown & Co., Limited, of Hatton, had on hand. To this there is not much to add, but Mr. J. Grieve, the manager at Hatton, in showing a representative of ours round the extensive Works the other day, named a few points of interest that will be new to our readers. At these Works—branches of which are now placed at Maskeliya and Norwood—there is a large quantity of local labour employed.

Messrs. Brown & Co. have in hand the remodeling of the factory at Craigie Lea, Mr. Keith is doing the brickwork himself, but the firm have in hand the iron-work and the roof. The building will be 118 feet long and 40 feet broad, and it will be supported by iron pillars. The machinery of the remodelled factory will include—two rollers, three driers, twelve horse power engine and boiler, water wheel, sifter, packer, fourteen horse power wheel.

Then the firm have in hand an aerial tramway at Warwick estate for Messrs. Finlay, Muir & Co. It is to be half-a-mile in length and to be made of half-inch rope. It connects Ambewella-road with the factory. Loads of 150 lb. in weight will be carried. It is to be worked by an independent motor and the motor is a Pelton.

It is noteworthy that in spite of a good many other makes, Soutar's Rollbreakers are still in demand, and several are in process of construction.

With regard to Oil Engines Priestman's make—the original inventor—is again coming to the

front. A heat igniter is now put on instead of the electric battery and the engines are doing better. One of the latest engines of Priestman's make is coming out to Kandapolla for use in a factory. It will be interesting to see how it compares with the old style. Priestman & Co., of Hull, were the early makers of oil engines, but their engines have in many places been superseded by other makes. They are trying to get the business back.

Messrs. Brown are also building a Withering house at Batalgalla, Dikoya: the dimensions of this are 100 feet by 40 feet, there being three flats. There are many other features of interest in the works at Hatton to notice, including a solid brass turbine of novel character; the pelton wheels, which are being used in some cases, instead of turbines; jets for condensing steam in an engine; winches for wire shoots: &c., &c. Heaps of old coffee machinery, gradually being melted down for use in other forms, are one of the points that attract the attention of a stranger.

PICKINGS.

The following is the text of a Proclamation issued by H.E. the Governor of the Cape and published in the *Government Gazette* of November 12th, 1897:—

Whereas it is desirable to prevent the introduction into this Colony of the destructive Coffee-blight known as *Hemiteia vastatrix*: Now, therefore, under and by virtue of the powers and authorities vested in me by Act No. 9 of 1876, intituled "Act to regulate the introduction into this Colony of articles or things which by reason of disease or otherwise might be injurious to the interests thereof," I do hereby proclaim, declare, and make known that I have made the Regulations set forth in the Schedule hereto for preventing the introduction into this Colony from beyond the boundaries thereof, of the articles and things specified in the said Regulations.

Any person or persons contravening any of these said Regulations shall, on conviction, be liable to a fine not exceeding £100 sterling, and in default of payment thereof shall be liable to imprisonment for any term not exceeding six months, unless such fine be sooner paid.

SCHEDULE TO THE FOREGOING PROCLAMATION.—The importation into this Colony, from places beyond the boundary thereof, of any coffee plant, or of any cutting, graft, or portion thereof, is hereby absolutely prohibited; and anyone importing or introducing any such coffee plant, cutting, graft, or portion thereof, shall upon conviction be subject to the penalty provided in the body of this Proclamation, and the addition thereto the plant, cutting, graft, or portion thereof, shall forthwith be destroyed.

WATER POWER.

Under the head of "Water: the Modern Rival of Coal," Mr. J. B. C. Kershaw, in *Chambers' Journal* for January, describes the development of the modern methods for tapping the almost limitless water-power of the earth by means of first, turbines (either 'reaction' or 'impact') and secondly, dynamos. He describes the wheel pit at Niagara as planned to hold ten turbines, so that when they are all in position 50,000 horse power will be produced at one station. The impact-turbine or Pelton wheel, he says, is principally used in the mining districts of the United States, though as our readers know they are not unknown in Ceylon. The article is a very instructive one and Mr. Kershaw points out that it is a curious fact that in Europe those countries rich in the possession of extensive

coalfields—namely England, Germany, and Belgium are extremely poor in their possession of natural water power: whilst Switzerland, France, Norway and Sweden have been highly favoured by nature in the number and the magnitude of their water powers.

WILD SPORT IN CEYLON.

HUNTING THE SAMBUR.

From Mr. F. Fitzroy Dickson's paper on this subject in the January number of *Travel* we take the following extract as illustrative of the interesting manner in which the writer has dealt with his subject and also of the character of the sport he describes:—

The next day was all that we could wish, and by daybreak we found ourselves at what is known as Round Patna, some five miles from where we were camped. This was always looked upon as a good cover, but the disadvantage was that, being isolated, if the deer took it into his head, he could go clean away from us, unless we were prepared for an all-day chase, as there was no open land by which to follow him. We were prepared for this contingency, however, and had each one of us put a few biscuits in his pocket, a precaution, as events proved, that was well justified.

A little stream trickled into the Round Patna at the upper end, and flowed through a luxuriant meadow. Here we took the pack and uncoupled. We had with us two seizers, Scotch stag-hounds, and these we kept in leash. It was my luck to hold them, and the bother they gave me, getting to one side of a tree when I wanted to go another, at times made me wish them somewhere else. "Grouach" and "Borap" were their names, and they were faithful, honest and staunch hounds as ever trod. Once uncoupled, the pack streamed all over the place, working with the keenness that characterizes a pack well handled and in good heart. Presently Marquis, a young dog of the first season, picked up a scent, which we ran down to the water's-edge and lost. Then Bugler took it up on the other side of the stream, and all at once three or four got on to it at once, and headed by old Melody, the pack were soon out of sight, having taken a bee-line up the face of the hill and into the jungle. As soon as they were over the brow of the hill we could hear nothing, and there was no help for it but to climb up after them as quickly as possible. Accordingly, up we went at a good swinging pace, and made for the highest ridge. Before reaching this, we crossed the line of the hunt, and there we saw the track of the stag.

"Men, alive!" cried W. with great glee, "he's of hoofs like auld hornie himself," and certainly the print showed that we had an old animal to deal with what would give us all we wanted and something more perhaps.

Well, we kept on that ridge running and panting and struggling for about an hour, and then found ourselves on the shoulder of one of the highest peaks. Every now and again we could hear the distant tinkle of the hounds, and we knew that we were in for it, and intended to see the game through if it took us a week. Presently we got into a nasty bit of jungle, a mixture of nilu and bamboo. Nilu, I might explain, is a jointed, succulent plant, which grows up in dense clumps, many acres in extent. There are several varieties of it, and all equally objectionable from their obstructive properties. It is easily cut with a knife, but it has the faculty of tripping you up and barring your passage. "Nilu" is the Tamil word for "Stop."

We were pretty high up now, and so worked our way across the face of the hill, but it was an awful task. We had to relieve one another at breaking the way, for such a tangle as bamboo and nilu is must be seen to be appreciated. The bamboo I speak of is, of course, not like the big cane that figures in

Japanese work. It is a trailer, not much thicker than a lead-pencil and as tough as whip-cord. It will give to any amount, but to break it is impossible, unless worked backwards and forwards like a piece of wire between the fingers. It is on this that the sambar feeds, and we always expected it.

The stag kept moving on steadily, and we had now been on the run for several hours, and began to think it was time he turned to bay. Evidently, from the way he managed things, he was a stayer. Presently we struck an elephant path one ridge that seemed to carry us in the desired direction. As it turned out, nothing could have been better, and a quarter of an hour brought us to where we could hear the hounds away below us in some stream, at bay. The seizers I hold in leash knew what was the matter and tried to get away, but the moment had not arrived for the utilisation of their services. We hurried as quickly as we could, for we knew that if we delayed too long the stag would regain his wind and then, if he started afresh, it would be all up for that day, at any rate. We soon found ourselves in a perfect forest of nillu, which for a moment threatened to utterly bar our way. Drawing my knife, I slashed viciously, whilst W., thinking he saw a clear passage, shered off to the left. I went on chopping like a backwoodsman, crawling, jumping and advancing. All at once I discovered the stream running before me clear of obstructions. In a moment I was in it, and, running along it, came in view of the bay.

In a little recess, backed by smooth, perpendicular rocks, stood a magnificent stag, his mane bristling, his head down, ready to beat back any attack. The pack stood round him, raising a row that made the forest echo. I had at once slipped the seizers, and at the sight of them and at the sound of my voice, "Yoicks, to him!" they made a frantic rush at the stag.

At that moment W. appeared on the scene, and we advanced to the attack together. The stag was fighting for his life, and dangerous, and we knew that we could not touch him unless he was well held. In a moment there was a confused mass of dogs and deer. With gigantic springs Grouach and Borap had covered the distance between them and the stag, and had seized him cleverly by the throat. How they evaded his antlers I cannot tell, for he was as quick as lightning; but they were quicker, and the other dogs piled in on top, and W. and I with them. Another moment, and, with a mighty, convulsive leap that threw off all the dogs except Grouach, the stag fell forward dead, both our knives having gone into his heart!

It was over! There he lay, as magnificent a specimen of a sambar as ever I saw. But for the seizers we should have had a hard battle to conquer him, for he was full of fight and go. Had we left him much longer he would probably have broken bay and got off altogether. As it was, however, we shouted like a couple of school-boys, and the hours of toil we had endured seemed but minutes, and the fatigue all disappeared when we looked upon this splendid beast lying there. Presently we were joined by the rest of our party in various stages of exhaustion and dilapidation, but all revived at the sight of our success. We sat down on the mossy bank and pulling out such grub as we had brought with us, ate it and washed it down with the cold water of the stream, tempered, I might add, with a few drops of Scotch whiskey from a flask that somebody carried. We all drank, and then we gave the dog-boy a nip, for he would have to come back the next day with coolies and carry the stag home.

CEYLON LIMITED COMPANIES IN 1897:

A list of all the local "Rupee" Capital Companies incorporated during last year; and also of the Sterling Companies registered in London, was published the other day in the *Ceylon Observer*. The former number a dozen and range from the

"Sinhalese Theatricals Company, Limited" with a capital of R5,000 to the Neboda, Oodoowerre, Gangawatte, Agra and Pitakandel Tea Estate Companies each of the five named having a capital of R500,000. The total (nominal) capital represented in the twelve new Ceylon Companies is R3,164,000.

Turning to the Sterling Companies, we find no fewer than twenty registered, representing a total (nominal) capital of no less than £3,392,500; but this includes the Kanau Devau Hills Produce Company, Limited, which is more properly an Indian Company, and has a capital of a million pounds to itself. So again the Indian & Ceylon Tea Trust Company (capital £250,000) cannot all be credited to this island, nor perhaps the Eastern and Ceylon Tea Estates and Trading Company with its £20,000 capital. Still the list for 1897 shows substantial additions to the roll of Ceylon Plantation Companies.

The following remarks from a contemporary are of interest in connection with this subject:—

There has existed during the year a tendency to amalgamate local concerns and to issue them on a sterling basis. One such scheme has been accomplished and the results are decidedly not encouraging. We refer to the Yatiyanotota, Weoya, and others. The two former were amongst the oldest of Ceylon Companies and were always pointed to as the most prosperous on the local share list, shewing 700 and 300 per cent premium respectively. These were placed on a sterling basis at near the rupee equivalent. Allowing for the issue of scrip at 50 per cent premium, the shares are now 20 per cent discount. Placing aside the cost of liquidation and reconstruction, even the most enthusiastic supporter of the scheme can scarcely look upon the venture with satisfaction. It is the popular idea that home investors are satisfied with 6 per cent. for their money—doubtless they are as a minimum, but there are contingencies to provide for, 1, Exchange; 2, Prices of produce; 3, War, famine, and disease. These are points that appeal to sound business men, who are the supporters we ought to endeavour to attract. At present we are supported by outside investors, ignorant of what they hold, and possibly first interested through advertisements and lured by the prosperity of old companies which have a splendid record, and which find a position in most prospectuses issued at home as indicative of what can be done. This class, when disappointed, air their misfortunes with persistent energy. Speaking of "decoys," perhaps the name and reputation of no Company have been of such service to promoters as those of the Ceylon Tea Plantations Company, whose splendid record has not been wasted when wanted to stimulate interest in the tea enterprise in Ceylon. The London Stock Exchange has been a weakness of some of our local financiers, but we think their affection was not reciprocated. During the boom a certain amount of interest was extended to Ceylon investments, but dealings were not a success; sales were made without finding a cover; and settlements were far from satisfactory. The capital of Companies in Ceylon was found far too small to command a ready market except on large margins, and the number of Companies entitled to a quotation was so small that it was not worth the attention required to investigate their merits. A point worth noting at the present time is that a number of local Companies are short of capital, and during the last few months this fact has been in evidence by the number of Companies making arrangements to borrow. This fact is of importance to investors who base their calculations on the usual statistics that appear in the local share lists. As an instance in point, we see in the *Gazette* that the Udabaga Coy. propose to borrow a sum of £11,000 sterling on a capital of R170,000. Considering the depressed state of the local market, and the depreciated condition of stocks representing good properties floated on the local market at prices considered reasonable by practical authorities and supported by local capital, we cannot but watch with interest the future of a num

ber of ventures recently introduced on the home market, consisting of properties at full prices and of more or less indifferent reputation. The public, we believe, are not committed to any large extent. The promoters and London Agents, as we have said before, hold the position at advantage, whilst the under-writers, though probably their "considerations" are not small, may be victims through the want of appreciation on the part of the public.

UPPER DIMBULA DISTRICT IN 1897.

Jan. 20th, 1898.

WEATHER GENERALLY.—The weather during 1897 was, on the whole, favourable for tea, the rainfall being slightly over the average and very well distributed.

THE RAINFALL here for the season, was 102.53 falling on 231 days against an average for the last 15 years, of 98.52 and 214 rainy days.

CROP.—With few exceptions crops were very satisfactory; estates as a rule having exceeded estimates and previous yields.

LABOUR SUPPLY.—Sufficient on most estates, but there are exceptions, as usual, to prove the rule.

TRANSPORT.—Foot and mouth disease caused a good deal of trouble for some time, but on the whole there has not been much to complain of.

ROADS.—The cart roads, especially those converging on Talawakele, were not what MacAdam would have considered perfect, but minor roads show a marked improvement during recent years.

RICE AND OTHER SUPPLIES.—These have been exceedingly dear during the greater part of the year.

The slip on the railway caused considerable inconvenience to nearly all of us as most estates now deal directly with Colombo for their food supplies, and as we do not lay in stocks except during the heavy monsoon months, almost all were on short commons and felt anxious for some time; but, thanks to the shrewd common sense of that Tipperary Scotchman, who is such an ornament and tower of strength to the Railway Department, we all worried through fairly satisfactorily.

GRIEVANCES.—These are really too numerous to mention; but low prices, high exchange, dear rice, and perverse London Brokers prevent most fellows from keeping as soundly as they'd like to.

A CEYLON TEA COMPANY PROPERLY DEFENDED

THE Dimbula Valley (Ceylon) Tea Company has been the object of a good deal of criticism since it came into existence; but it has held on its way and paid successive dividends after a most satisfactory fashion. Nevertheless, the "Investors' Review"—rightly valued in London, for the honest, outspoken criticism of its Editor, Mr. Wilson, a hard-headed Aberdonian—had, in its October issue, an attack on the "Dimbula Valley" calling it "A Weak Tea Company." This was not seen by the Managing Director for some time after its appearance; but when it came under his notice, he immediately wrote a reply which we think very thoroughly disposes of the attack. The letter is inserted in the issue of Jan. 7th as follows:—

(From the *Investors' Review*, Jan. 7.)

We shall be as pleased as Punch if the anticipations in the following letter come true:—
DIMBULA VALLEY (CEYLON) TEA COMPANY, LIMITED.
16, Philpot-lane, London, E.C., Dec. 1, 1897.

Sir,—My attention has been drawn to your article in the *Investors' Review* for October headed "A Weak Tea Company." With reference to the writer's comments on the Dimbula Valley (Ceylon) Tea Company, Limited, I can only say they are unfair in the comparison drawn between this company and the other two named.

In the first place, the writer of the article adds to the Company's capital £6,250, the amount of the mortgages which were taken over when the estates were purchased. These mortgages could only be paid off at certain dates, but the company hold the amount ready to pay them at due date.

In estimating whether our capital is high or low the amount of mortgages should, therefore, not have been added. Then our profit of £14,595 1s 8d was practically derived from 1,440 acres of bearing tea, or at the rate of £10 per acre net profit, whilst I assert without any fear of contradiction that the average profit for the whole of Ceylon is not over £5 per acre.

This shows that the dictum is all wrong of the writer of the article, to the effect that "any tea company's capital which stands over £50 an acre is over capitalised," because it is manifest that a company's gardens which turn out a net profit of over £10 an acre must be worth more than those giving only half that, or even less. The only estate belonging to the company absolutely in full bearing last year gave over £16 per acre profit, and I am aware that it has done something like this for several years. Therefore, no rule such as the writer lays down is applicable to Ceylon, or any other gardens.

I would, in conclusion, point out that in judging the stability or otherwise of a tea company as a safe dividend-paying concern, the net profit per pound of tea realised is the most important guide. A company whose net profit per pound is but a penny, is surely in a very different position from one whose profit is 4d as was, and, I hope, always will be, the position of this company.

Should tea drop 1d a pound, a capital of £50 would be a bit high, would it not?—Yours faithfully,

JAMES SINCLAIR.

There can be no doubt that the estates belonging to the Dimbula Valley Company are all exceptionally valuable—producing heavy crops of high-grown, high-priced tea.

PLANTING PROSPECTS IN NORTH BORNEO.

We take the following from the letter of a resident of long experience in North Borneo, dated Sandakan, 5th Jan. :—

"You may like to note as news from here that the present prices and future prospects for coffee in North Borneo are filling planters with consternation, and that parts of the forest already felled for coffee are being given up for that purpose and are being devoted to Cotton and Coconuts instead, while efforts are being made to plant up Rubber both Para and Willoughbia. It is a great pity that coffee has fallen in price, as coffee growing was rapidly spreading and offered an easy and expeditious way of making the country prosperous. The size, health and cropping powers of our coffee trees is undeniable, but what is to be done with the price at \$20 and not likely to stop long there either?"

Well-prepared good "plantation coffee," however, still keeps up wonderfully in price.

THE GERMAN COMMERCIAL EXPEDITION TO CHINA AND JAPAN—having completed its work, (among other trips, penetrating 1,100 miles up the Yangtsekiang in China) is now broken up. Dr. Hermann Schunacher, jr., the accomplished Secretary, with some of the members is now on the way home and the party have been visiting our hill-country. In all there were ten experts in the Expedition: two of these are now in India and two in Siam, afterwards to visit Java and Sumatra. Altogether a valuable body of information must have been compiled by the Commission and Dr. Schunacher is certain to prepare a very useful interesting Report.

IMPROVED TEA MACHINERY.

In our issue of December 3rd we referred to Mr. S. C. Davidson's exhibit of a working model of his new patent "Sirocco" Tea Roller at 12, Bishopsgate Street, C.C., and since then he has sent us copies of three additional testimonials as to the practical working of those machines which he has received—two from Ceylon and one from India. Although the machines to which these testimonials refer have only been at work during the past season the testimony in their favor which we quote will be of interest to our readers, as in each instance the machines have been in use a sufficient time to thoroughly test their working capabilities. The testimonials are as follows:—"From J. Armitage Ogden, Esq. Kirklees Estate, Udapussellawa, Ceylon, November 1897. I have used the Sirocco Roller for the last two months, and am much pleased with it. It takes very little power to drive, keeps the leaf cool, and rolls more evenly than any Roller I have seen. A very strong point, I consider, is the small quantity of broken tea, and even with dry, over-withered leaf the proportion of broken tea is very small, and I have no hesitation in recommending anyone to use it, particularly where short of power. The factory oodles like it because it requires no attention whilst working, and is easy to fill, and no trouble to clean after work."

"From W. R. Waller, Esq., Poyston Estate, Dikoya, Ceylon, November 19th, 1897. I am very well pleased with the work the Sirocco Roller does. It works easily with little or no attention, and certainly does not take more than 2 H.P. to drive it. It makes a good wiry tea, well twisted, tippy, and I find less choppy than other rollers. I think the pressure from the ploughs inside, combined with weight of tea, quite sufficient. My teas have been valued and sold for more since I used this roller."

"From Henry Weir, Esq., Kalline Estate, Cachar India, November 22nd, 1897. Davidson's Sirocco Roller is doing very good work indeed," we may also mention that Mr. M. Kelway Bamber who is already well-known to tea planters as an authority upon all matters touching the manufacture of tea, was amongst Mr. Davidson's visitors when he was showing the model of his roller in London at the above address, and Mr. Bamber has since then expressed it as his opinion that the rolling motion given to the leaf in this machine, and the coolness which is at the same time maintained in the leaf during the rolling process, could scarcely be surpassed, while the machine itself is a combination of strength and cleanliness, with evidently a great economy of power. Mr. Bamber further stated that, after having carefully perused Mr. Davidson's new catalogue, he considers that in the machines now illustrated and described for the first time, and also in the older machines, with the improvements which Mr. Davidson has lately made on some of them, the several, chemical and other requirements for the manufacture of good tea are eminently combined.—*H. & C. Mail* Dec. 31st.

RAMIE FIBRE MACHINERY AND PROSPECTS.

LONDON, Jan. 7.

Yesterday I was fortunate enough to catch MR. J. M. MACDONALD, of Ramie fame, at his office in Victoria Street, Westminster—a one of a suite of comfortable offices tenanted by Messrs. MacDonald, Boyle & Co., engineers, and Boyle Fibre Syndicate. Mr. MacDonald was in excellent spirits, and spoke most hopefully of the prospects of his decorticating experiments, and of their probable outcome. He will remain in London until late in April, when he intends to start for Johore to superintend the operations in ramie preparation for which, as you are aware, arrangements have already been entered into. "A number of enquiries," said Mr. MacDonald, "have been made here since I arrived in England with re-

ference to the machinery for decorticating, and several Ceylon planters have called on me. One machine has already been got ready for almost immediate dispatch to Ceylon, to the order of Mr. J. Manley Power, who intends to use it for experimental purposes on.

BON ACCORD ESTATE, BOGAWANTALAWA.

I believe Mr. Manley Power purposes to try ramie at first over an area of about seven acres. The machine is to be sent through our agents, Messrs. Lee, Hedges & Co., and while I am on my Johore trip I shall pay a visit to Ceylon in order to superintend affairs connected with the decorticating experiment. I am due to arrive in Johore about the middle of May, and I propose to stay a week in Ceylon." Conversing on the subject of ramie cultivation generally, Mr. MacDonald spoke of what is being done in Jamaica, and referred me to the last-arrived issue of the *Jamaica Daily News Letter*, in which has given an interesting account of the steps that are being taken to begin the cultivation and preparation of ramie on a large scale.

"JAMAICA ISN'T IN IT WITH CEYLON, to my mind," said Mr. MacDonald; "Ceylon could, I think, do very much better than the Jamaicans." It seems that H.E. the Governor of Jamaica has given the Jamaica Fibre Company, which has been recently formed, his blessing, at the same time pointing out "the danger of the policy of letting any particular industry absorb or monopolise to too great an extent the effort and energy of the enterprising agriculturist." According to the editor of the *Jamaica News Letter*, who has a leading article on the subject, the result of enquiries made of a large number of people whose names were obtained from the Botanical Department is that in most of the parishes of the island ramie will thrive. Nine-tenths of the replies showed that very little care was taken in the cultivation, yet four crops were obtained in the year. Then we come to the Jamaica figures. It is estimated that an acre of ramie will give four cuttings per annum, 40 tons of green stems, "which green stems would be worth to a Central Factory 10/ a ton. An acre would, therefore, yield £20, less the expenses for cutting, which are estimated to be £9." In order that the planters may figure out the correctness of this it is stated that "one man, working 300 days a year, can cut the produce of two acres, and the cost of labour has been estimated at 1s 3d per day." It is mentioned that an offer has been received from the Midlands Spinning Company (England) of £42 a ton for all flasse that the Company produce in the next five years.

THE RAGALLA TEA ESTATES, LTD.

The Third Annual General Meeting of Shareholders was held at the Offices of the Company, 39 Lime Street, London, E. C., on Tuesday, 4th Jan., Mr. C. E. Strachan, presiding.

After the notice convening the Meeting had been read, the CHAIRMAN, in moving the adoption of the Report and Accounts, said.—The Report and Accounts have been in your hands for some days, and I presume you will take them as read, but you will, no doubt, expect to hear something from me about the past season's working and our prospects. You will see that we are unable to pay a further dividend on the Ordinary Shares, and I am sure you all feel disappointed, but certainly not more so than your Directors, who own a very large number of Shares in the Company. Circumstances have, unfortunately,

been against us; the crop turned out 50,000 lb. short of estimate, owing to an unfavourable season; prices were nearly 1½d per lb. less than we had every reason to expect; rice showed a heavy loss owing to the famine in India; and exchange was somewhat higher than we anticipated. All these adverse circumstances have reduced the profits. When we purchased the Ragalla Estate it was principally planted with Coffee, and we depended chiefly on this product for our income. In the course of time it became evident that Coffee was failing us, bug and leaf disease, year after year, were destroying its vitality and reducing the crops in spite of cultivation, and we saw that if we wished to make the Estates productive, and valuable to the Shareholders, we must push on with the cultivation of Tea as quickly as possible. Tea and Coffee will thrive together for a short time, but as soon as the Tea gets its head above the Coffee the question arises, which has to be eradicated. In our case there was no difficulty in deciding, but we deferred uprooting the Coffee as long as possible, so that we might have an income from this product towards meeting our expenditure and earning dividends, and also to give us time to get the Tea well forward. A difficult time is bound to arise during the change, and that time arose last season. A great part of the Coffee was removed, but the Tea—owing to the unfavourable season—did not respond as well as we expected. We have, however, rounded the corner and, as you will see, the tea crop this present season is estimated at 490,000 lb. and we have every reason to believe that this estimate will be secured. We could have adopted the policy of doing nothing, simply harvesting the crops and working the estates in the cheapest way, and we might in this way have earned enough to pay you a dividend for a few years, and perhaps have put aside a certain sum to reserve, but what would have been the final outcome of such a policy? In a few years the coffee would have died out, and we would have been left with a small sum in reserve, but practically unremunerative estates.

What then is your position now? You have no reserve certainly, but you have estates in the highest condition of cultivation, roaded, drained, and planted in the best possible way, with factories and buildings erected. The estates are, we consider, more valuable than the amount they stand at in the books, and will give larger returns each season, thus enabling us, as I hope, to earn good dividends. We feel that in the course we have adopted we have done the best for the estates.

The adoption of the Report was seconded by Mr Evans.

Mr. BISHOP enquired as to the date for closing the accounts, as last year's Balance Sheet was made up to 31st July. He also asked about the future of the Kelburne property, when it was expected the 309 acres non-bearing would be fully productive, and if the estate would earn enough to cover the interest on the purchase-money. In reply the Chairman stated that the Ragalla accounts were for eleven months and the Kelburne accounts for twelve months, the 30th June being chosen as a convenient date for closing the books for both Estates. As to Kelburne the acreage at present non-bearing would be in full bearing in two to three years, and as all the land had been planted with Tea before the Coffee had been removed the Tea was well forward, and the property itself was considered most valuable and fully capable of earning sufficient profits to meet the required interest.

The CHAIRMAN then put the motion to adopt the Report, which was carried unanimously.

On the motion of Mr. HARWOOD, seconded by Mr. EVANS, Mr. HANNEN was re-elected a Director of the Company.

Mr. W. L. STRACHAN proposed the re-election of the Auditors, Messrs. FULLER and WISE, and this being seconded by Mr. RICHARDSON, was duly agreed to.

TRADE REPORT.

(From the *Chemist and Druggist*.)

London, Jan'y. 6.

COCAINE.—The manufacturers quote hydrochlorate from 10s 3d to 10s 6d per oz. nominally, and second-hand holders from 9s 9d to 10s per oz. So much stock is held by the latter that the market is lifeless.

COCA-LEAVES.—The available Huanoco is of rather poor quality, and is offered at 8d. Truxillo leaves at 6d to 8d, but the colour of these is not good.

PLANTING NOTES.

CINCHONA AUCTIONS.—The London cinchona auctions for 1898 have been fixed for the following dates: January 25, February 15, March 15, April 26, May 24, June 21, July 19, August 16, September 13, October 11, November 8, and December 13.—*Chemist and Druggist*.

THE EUCALYPTUS-OIL INDUSTRY.—The Tasmanian Eucalyptus Oil Company, Ltd. has recently opened a new distillery at Sandy Bay. The first charge of the still was started with some ceremony by the manager and the chief distiller, sample bottles of the "brew" of "Platypus" oil being distributed among those present.—*Chemist and Druggist*.

RAMIE MACHINERY IN CEYLON.—Our London correspondent reports that a well-known Bogawantalawa proprietor is getting out a decorating Fibre Machine from Messrs. MacDonald, Boyle & Co., to deal with Ramie, grown over some seven acres on his property. Great interest will be felt in the results of this experiment.

GAME PROTECTION.—"E.G.R." replying chiefly to our contemporary of the "Examiner" shows very clearly the wide distinction which should be drawn between the Sinhalese villagers in out-of-the-way districts and the peripatetic as well as ubiquitous hunting and trading Moorman, bent on getting all he can out of the forest, of hides, horns, &c., no matter what may be the rules for Game Protection.

THE CULTIVATION OF ORANGES FOR EXPORT.—*Indian Gardening* publishes an article on the English fruit supply, and suggests the possibility of Indian exportation of oranges to compete with other countries in the English market. It proposes that the Government should set the example by establishing an extensive orange orchard in Nagpur, or Delhi, where oranges of the finest varieties grow to perfection, and develop the export business. "The local fruit-growers would, as soon as they found what a paying business it was, take over the orchards and work them among themselves. That it would pay handsomely to grow oranges for export scarcely needs to be insisted upon, because the finest oranges of Sylhet, the Punjab and Nagpur sell at a rate at which they would undersell the produce of every other country in the world in the English market.—*Pioneer*, January 16th.

DEAFNESS. An essay describing a really genuine Cure for Deafness. Ringing in Ears, &c., no matter how severe or long standing, will be sent post free.—Artificial Eardrums and similar appliances entirely superseded. Address THOMAS KEMPE, VICTORIA CHAMBERS, 19, SOUTHAMPTON BUILDINGS, HOLBORN, LONDON.

TEA RECRUITING IN INDIA.

In connection with the proposed Central Tea Recruiting Agency, a meeting was held on Tuesday at the Calcutta Chamber of Commerce to receive the Report of the Provisional Committee, to elect a Board of Management, and to consider, certain Resolutions. Sir Patrick Playfair presided, and in a short but appropriate speech introduced the business of the meeting. The important function of electing the five Calcutta members of the Board of Management was then proceeded with, and the result of the voting was in favour of the following firms:—Messrs. Begg, Dunlop & Co., Messrs. Williamson, Magor & Co., Messrs. Shaw, Wallace & Co., Messrs. Finlay, Muir & Co., and Messrs. Octavius Steel & Co. The last-mentioned firm tied with Messrs. McLeod & Co., but the latter retired in its favour. The remaining resolutions were then submitted and carried unanimously. The newly-formed Board of Management will proceed to formulate the details of the scheme, so that all may be in readiness to start the agency by the 1st of November next.—*M. Mail*, Jan. 29.

INDIAN TEA SALES.

(From *Watson, Sibthorp & Co.'s Tea Report*.)

CALCUTTA, Jan. 27.

11,285 packages of tea changed hands in the sales held on the 21st instant. The market was quiet, good liquoring teas, which were in small supply, were wanted and sold fairly well, all other kinds sold irregularly but without material change. There was a fair amount of business done for Australia, but the Bombay buyers were again very quiet.

The average price of the 11,285 packages sold is As. 5-2 or about 7d per lb. as compared with 11,249 packages sold on the 21st January, 1897 at As. 5-8 or about 7d per lb. and 13,649 packages sold on the 22nd January, 1896 at As. 6-3 or about 7d per lb.

The Exports from 1st April to 24th. January from here to Great Britain are 128,444,645 lb. as compared with 126,925,775 lb. at the corresponding period last season and 115,655,415 lb. in 1896.

NOTE.—Last Sale's average was As. 5-7 or about 7½d.

Exchange.—Document bills, 6 months' sight, 1s 4-5-16d.

Freight.—Steamer—£2-1-3 per ton of 50 c. ft

PLANTING NOTES.

UNDERSTANDING AMONGST CINCHONA IMPORTERS.—We hear from Amst^{er}dam t^{hat} a conference of importers of Java cinchona bark was held there a few days ago at which an understanding was arrived at to endeavour to regulate the price of the article to a certain extent, by offering only moderate quantities at the auctions, and by agreeing not to sell below a fixed minimum price. The auctions of January 20, at which only a moderate quantity is likely to be offered will show whether this understanding is a fact or not.—*Chemist and Druggist*.

THE NEXT BATCH OF TROUT OVA.—The next batch of trout ova are expected about the 10th proximo, and the necessary preparation, are being made for their receipt in Nuwara Eliya. The trout-house behind the Kaccheri premises has been thoroughly overhauled under the supervision of Mr. Elhart, and the plant in the building is all being attended to. Of the four hatching boxes now in readiness three are new ones. New piping has been got out, and every precaution is being taken as regards the filtering of the water and the sieving of the sand; while the two ponds which supply the water have been cleaned out.—*Cor.*

COLOMBO COPPERAH MARKET.—This market is practically lifeless owing to the scarcity of copperah. During last week the arrivals were few, and this week the market opened with blank disappointment. There was a fairly good demand both from shippers and millers, and prices ranged from R32 to 38-75 per candy. According to the present market value of oil, which forms the basis of the price of copperah, and leaves a margin for the scarcity of crops, prices paid are fair. But with a reduction on them, they will compare favourably with the price for oil.

CINCHONA IN BENGAL.—Two months ago we referred to the manufacture of quinine and cinchona febrifuge by the Bengal Government during the last official year. It is to be observed in this connection that the cinchona plantations are gradually being enriched by the planting of *Cinchona Ledgeriana* seedlings, no fewer than 24,750 of such plants having been put into the ground, as compared with 20,000 seedlings of the hybrid cinchona. The policy now adopted is to plant the quinine-yielding *Ledgeriana* almost exclusively, and the result ere long may be that the Government will be able to supply all its own needs, if not more exclusively from its own plantations.—*Chemist and Druggist*, Jan. 15.

THE TRADE IN TEA SEED.—The great demand for Tea seed in the season 1896-7 led to a strong rise in the price of imported seed, and large profits were made by far-seeing importers. This brought about the usual consequences. Seed has been brought down in large quantities from Calcutta during the last two or three months, the market has been flooded, and at the same time the demand has declined. The price of seed has fallen rapidly, and we hear that heavy losses have been incurred by Colombo firms, one firm alone having dropped R10,000. The latest news is that another firm, who imported largely, have had a very large consignment of seed left on their hands, it being found to be rotten on arrival at Colombo.

"THE AGRICULTURAL GAZETTE" of New South Wales, issued by direction of the Hon. Sydney Smith, M.P., Secretary for Mines and Agriculture Volume VIII. Part 12. Edited by W. H. Clarke. Contents for December, 1897, are the following:—Useful Australian Plants; The Grading of Wheats, Judging the Milling Qualities of Prize Wheats at Shows &c.; Chemical Notes; The Kerry Cow; San Jose Scale; Some Notes on Draining; Green Manuring; The Importation of Dairy Produce to Great Britain; The Influence of Bees on Crops; Bee Calendar for January; A Sulphuring Bung; Orchard Notes for January; Practical Vegetable and Flower Gardening for January; General Notes; Replies to Correspondents; List of Agricultural Societies' Shows; Label for Specimens.

A SUBSTITUTE FOR COFFEE.—The United States Consul at Crefeld writes:—Under the name of Katherine's Malz-Kaffee-Fabriken, factories have been established in Germany—of which one exists in this consular district, at Merdingen-on-the-Rhine, and others at Munich and Berlin—for the purpose of manufacturing a coffee substitute from cereals. The invention relates to an improvement in preparing the same, which consists in applying to the grain, during the steeping process, an electric current proportionate to the quantity and quality of the grain, whereby the proteid substances existing in the grain are altered in such a manner that, in the subsequent roasting process, only a small quantity of the products of decomposition (as pyridine and its derivatives, which are objectionable to the taste) can be formed, a substitute pleasant to the taste being obtained. Under this patent, factories have also been established in Austria, Italy, France, Switzerland, and Sweden. The inventor has also applied for a patent in the United States.—*British Trade Journal*.

COLOMBO PRICE CURRENT.

Furnished by the Chamber of Commerce.)

Colombo, Feb. 1st, 1898.
 EXCHANGE ON LONDON: CLOSING RATES. Bank Selling Rates:—On demand 1/3 7-8 to 29-32; 4 months' sight 1/3 29-32 to 15-16; 6 months' sight 1/3 31-32;

THE AGRICULTURAL MAGAZINE, COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for February:—

Vol. IX.]

FEBRUARY, 1898.

[No. 8.

SEASON REPORTS FOR DECEMBER, 1897.

ESTERN Province.—Paddy. Maha crops in blossom and in some parts in ear. Fields for Yala paddy in preparation in a few districts. Fruits and vegetables scarce. Rain fell generally over the province. Paddy prospects fair.

Central Province.—Paddy. Maha crops blossoming (in some parts being transplanted) in the Kandy district, prospects good in the Matale district where the fields are in plants, in ear in the Kotmale district where the prospects are also good; ploughing for Maha in Walapane and Uda Hewaheta. Rainfall in Matale 16·74 in.

Northern Province.—Paddy. Crops that survived the drought are in blossom and ear. No cattle disease reported in the Northern Province. Rainfall at Jaffna 17·18 in., in Mannar 19·32 in.

Southern Province.—Paddy. In ear in all the pattus in Galle district; cultivation under Walawe channels commenced; sowing for Maha at Tissa over and crop in blade. Prospects in the Province generally good. No cattle disease reported. Rainfall in Galle 4·98 in.

Eastern Province.—Paddy. Some damage by drought to the Munamri sowing in Batticaloa, but out of 30,000 acres, 23,000 are in excellent condition; crops thriving in Trincomalee. Rainfall in Batticaloa, 29·17 in., in Batticaloa 27·22 in., except in Batticaloa south, the province is free from cattle plague.

North-Western Province.—Paddy. Crops in various stages, prospects fair; some damage done

by the paddy fly in the Puttalam district. Two cases of murrain in the Chilaw district. Rainfall 4·83 in Puttalam.

North-Central Province.—Paddy. In early stage^s of growth. Rainfall 18·28 in. in Anuradhapura. Cattle disease on the decrease.

Province of Uva.—Paddy. Harvesting of Yala (somewhat damaged by rain), Maha cultivation-going on. Chena crop prospects good; health of cattle satisfactory. Fruits and vegetables plentiful and cheap.

Province of Sabaragamuwa.—Paddy. Crops not damaged by floods in good condition. Province free from cattle disease. Rainfall at Ambanpitiya 16·85 in., in Ruanwella 12·02 in.

DENITRIFICATION—THE OTHER SIDE.

In the November number of the *Agricultural Magazine* there was published a *resumé* of an article by Dr. Somerville on "Denitrification." In the *Mark Lane Express Almanac* appears a contribution from the pen of Dr. Bernard Dyer, in which that well-known authority critically examines the experiments referred to in Dr. Somerville's article. Referring to the work of the German investigators the writer says:—

"The discovery may throw some light on the failure of artificials in some English Agricultural experiments to make any material or satisfactory addition to the produce obtained by dressings of dung, and there is no reasonable doubt that dung, under some circumstances, may be a wasteful instead of an economical addition to the soil; nevertheless, the vast mass of practical experience of good effects following the use of dung makes it difficult to believe that the circumstances under which its action is baneful rather than beneficial to the farmer are the frequent circumstances of every day farming, and it is impossible to avoid a hope that it may eventually be proved that the conditions in which these ill-effects arise are exceptional rather than general in practical field work. German investigators are, however, thorough in their work, and no doubt the subject will continue to receive attention until its practical side is completely elucidated."

In 1891 Dr. Dyer and Mr. Rosling carried on some experiments in the manuring of cabbages. Dung alone gave an increase of 5 tons 13 cwt. per acre over the unmanured crop. The yield was somewhat decreased where superphosphate alone was added to dung. Where nitrate of soda and dung were used the increase rose from 5 tons 13 cwt. to 7 tons 6 cwt. When "super" and nitrate, either with or without salt, were both added to dung, there was a further increase over the dunged crop up to nearly 7 tons per acre. Guano when added to dung raised the increase from 5 tons 13 cwt. to 7 tons 15 cwt.; two cwt. of nitrate added to dung and guano gave $1\frac{1}{2}$ tons more, while the addition of 2 cwt. more of nitrate gave still another ton of cabbages, the addition of salt to the dung, guano and nitrate making the increase 2 tons greater, bringing it up to 12 tons 8 cwt. or nearly 7 tons more increase than was made by dung alone.

Here then, in these experiments, the dung alone gave a substantial increase, which was more than doubled by the judicious addition of artificials. It will further be observed that there was no indication of the alleged depressing action of dung, nor of the intensifying of that action by superphosphate. Dr. Dyer gives the details of another series of experiments carried out in 1892, and concludes by saying: Here again we have chemical fertilizers working well by themselves, and dung working well by itself, with a largely increased advantage from the use of both together.

Again, Dr. Dyer refers to an extensive series of experiments conducted by himself and Mr. Shrivell in Kent, where the dung used was by

no means well-rotted stable manure, the result of which were that dung with phosphates and nitrate of soda produced $1\frac{1}{2}$ tons more of crop than the artificials without dung.

These experiments were extended to a large variety of crops, and their general result was to show that though a full dose of artificials produces better results than dung alone, yet the heaviest crops are most frequently grown where a moderate dose of dung is used in addition to a liberal supply of artificials. It undoubtedly, however, occasionally happens, says Dr. Dyer, that the plot heavily manured with artificials without dung beats the similarly manured plot to which dung also is applied, but he points out that this is *not generally* the case. The chief economical value of dung, as pointed out, lies in its mechanical action which, however, says the writer would be too dearly purchased if dung has the destructive action on nitrate which the German experiments attribute to it.

Dr. Dyer honestly confesses that the results of the experiments detailed by him do not go to prove that dung is not destructive to nitrates, but that they indicate that the destruction, under at any rate some practical conditions, is not large enough to render the addition of artificials to dung otherwise than advantageous and economical.

With reference to the action of phosphates and kainit in intensifying the denitrifying action of dung, Dr. Dyer points out that this is directly contrary to the experience of Holdefleiss of Proskau (given in the R. A. S. E. Journal for December, 1893) who found that a dung heap of 6 tons, left uncovered, lost in six months 23 per cent nitrogen, and that when 6 per cent of kainit was introduced into a similar heap, no nitrogen was lost. When phosphatic gypsum was used there was again no loss of nitrogen. Holdefleiss also found that the dung treated with potash salts produced double the increase of potatoes produced by pure dung; while the dung treated with phosphatic gypsum produced four times the increase.

In an experiment with wheat, dung with phosphates gave an increase of grain $2\frac{1}{2}$ times as large as that given by dung alone, while dung with potash salts gave nearly three times the increase.

Dr. Dyer thus concludes his practical article: Next to the great discovery of the special source of nitrogen in leguminous crops, the subject is one of the most interesting, as well as the most economically important, that agricultural chemists have attacked in modern times, and it is so complicated that it will probably hold the field for some time to come. Meanwhile, we are all indebted to Dr. Somerville for his timely, if somewhat disconcerting article.

OCCASIONAL NOTES.

The prize offered for the best milch cow at the last Horse and Cattle Show held on the Havelock Race-course was awarded to the Government Dairy's "Mary Girl."

The School of Agriculture re-opened after the Christmas holidays on the 15th January. The

number of applications for admission received was larger than it has been for some years past.

A Reading Room, where a large number of Agricultural Journals are laid on the table, has been opened at the School, and is available to the students and any visitors who may wish to make use of it.

Dr. Somerville, of the Durham College of Science, the contributor of the important paper on Denitrification which we summarised in our November number, writing to us on December 28th last, says:—"I am interested to learn of the manner in which your crops are fertilized, and I should think that if they receive a dressing of farmyard manure to the extent of 20 to 30 tons per acre, they will not require a great deal of other substances. I am not sure that any great loss would occur from mixing organic (inorganic?) substances with properly decomposed farmyard manure. It is mainly when that substance is in a raw condition that it is likely to be a serious source of loss. Your suggestion to defer the application of nitrogenous manures for two or three months after the dung has been applied will certainly prove effective in preventing loss."

We are glad to learn through Dr. Somerville that he believes Prof. Wallace's health is now much better. This is good news, as the last information we had of the Professor gave the very worst accounts of him.

Mr. A. R. Jeremiah of Krian, Parit Buntar, Straits Settlements, returned to the Straits early in January after going through a course of two years' study at the School of Agriculture, Colombo.

Mr. Edward Elliot, late of the Ceylon Civil Service, who is now engaged in agricultural work, in a letter explaining his inability to attend the late prize-giving held at the School, wrote:—"I trust you will have a successful meeting and some good speeches, and that someone will impress the necessity for liberal expenditure on both agricultural education and experimental cultivation. Nothing can be achieved without this, and unless it is continued for a very long period, if not indefinitely. The idea of agricultural instructors was an excellent one, but they were starved and expected to give illustrations and show results without any funds. I saw this and tried to remedy the mistake . . . and secured data which were valuable, and the correctness of which I have since verified, besides tangible results proving the correctness of the methods followed. Efforts in Ceylon are too spasmodic, and there is too great an anxiety to see "will it pay" within a very limited period of time. They seem to be ahead of us in this respect in India, and of course the Australian system of agricultural education, theoretical and practical, is splendid, and the Governments there do not grudge a large outlay. Look at the breed of cattle. What has Government done to improve this? Sir Hercules Robinson many years ago introduced some stud-bulls. Unfortunately they

were not very suitable—too big for the mates available in this country. They were soon sold off, though they were slowly fulfilling their purpose. This subject wants taking up, but there is no use issuing circulars to Government Agents and not giving them funds to carry out any plan agreed on. A sum of £10,000 a year would be well spent on this subject, and should be guaranteed for ten years to enable work on a regular system.

The Government Dairy has now paid back all the advances amounting to £11,500 made by Government from time to time for the working of the Establishment.

It is proposed to hold an Agri-Horticultural Show in Colombo about the middle of the year. The School of Agriculture grounds are spoken of as the probable site of the Show.

The second batch of Forestry students will complete their course of Study in February, and a new class admitted at the beginning of March next.

The following publications have been received and are acknowledged with thanks:—

Foreign.—Queensland Agricultural Journal, The Agricultural Journal of the Cape of Good Hope, The Journal of the Royal Agricultural Society, Transactions of the Highland and Agricultural Society of Scotland, Agricultural Ledger of India (No. 17 of 1897). The Scottish Farmer, The Indian Agriculturist, Barbados Agricultural Gazette and Planters' Journal, The Australian Tropicalist, The Sugar Journal and Tropical Cultivator (Mackay, Queensland), Central African Times. Our thanks are due to Mr. F. H. M. Corbet for copies of the Imperial Institute Journal and Pharmaceutical Journal, to Mr. John Ferguson for the Journal of the Society of Arts, Agricultural Gazette of New South Wales, Live Stock Journal Almanac, Mark Lane Express Almanac and Agricultural Annual, and the Adelaide Observer.

Local.—The Magazines of St. Thomas' College and the Royal College, Our Boys, The Ceylon Review, Tropical Agriculturist, Ceylon Churchman, Ceylon Forester, St. Paul's School Magazine, Circular No. 3 of the Royal Botanic Garden.

The Tick question has for some time been engaging the close attention of scientific and practical agriculturists in the Southern Continent. We have now received a request (through Mr. J. Drieberg, District Engineer, Puttalam) from Queensland for information regarding our local varieties of the Tick, together with preserved samples of the Queensland Tick and bottled solutions for sending samples of local specimens. We have referred the matter to the Colonial Veterinary Surgeon, Mr. G. W. Sturgess, for his report.

CALATROPIS FLOSS.

Referring to the floss of *Calatropis procera*, Mr. Cross, Scientific Referee on Fibres to the Imperial Institute, reports that it is an extremely interesting type, containing a very high, and, in his experience, unique percentage of

furfural (an oily product obtained on distilling bran with hydrochloric acid, but also afforded by all fibrous substances in a greater or less degree). He adds, however, although it may find use for some applications of floss fibre, its somewhat unfavourable chemical characteristics are not likely to recommend it to the spinner in view of the present low price of cotton (at the end of last year).

The practical expert referee on fibres (Mr. C. E. Collyer) to whom the floss was submitted, has furnished the following report:—This particular floss was in considerable demand in the markets a few years ago for fancy textile purposes, but owing to the difficulties presented by the variations in the quality of parcels supplied, and to the intermittent supply when requirements arose, the material has dropped out of use. The quality of the Indian growth is inferior to the product of Java, which is probably derived from *Calotropis gigantea* (the Ceylon species), small samples of which have occasionally been received from India. The specimen now submitted is of fair colour, and of rather short staple somewhat towy in character, containing an excessive quantity of inferior immature fibre and seed fragments.

Mr. Collyer is reported to have inspected many varieties of the floss in question, mostly from Calcutta (where it is sometimes called "Akund cotton"), which were mostly inferior to the sample referred to in the above report. These samples were sold at as low a price as one penny per pound, and there was but little demand for it even at that price. The trade in the floss, it is thought, may possibly be revived if a moderate but continuous supply can be guaranteed. If of good quality, the price it would realize ought to range from 4 to 5 pence per pound, c.f. and i. terms. In packing for sale, the floss should be handled as little as possible, the pods and seeds being entirely removed, and the floss left in its natural condition unopened; any discoloured portions should be separated and forwarded separately. The bales received in London from Java usually contain 80 to 90 lbs. of floss tightly sewn in canvas, not pressed. In a letter to the *Ceylon Observer*, dated 24th May, 1895, Messrs. Thirkell & Co. wrote: "In conclusion we would ask for samples of the silk cotton or floss from the seed pod of the *Calotropis gigantea* or *Mudar* for which a demand appears to be springing up, present value about 6d. per lb. landed in London."

Later in the same year samples of wara floss were sent with other fibres from the Colombo School of Agriculture to London for report, but no definite opinion was received as to its value, the only remark made being that it was of no use in the fibre (rope) trade. The value of the floss as remarked above is, however, for fancy textile purposes.

FRUIT CULTURE.

(Continued.)

On no account should the common custom be followed of bottoming every tree-planting hole with a shovelful of manure under the idea that the tree is getting thereby a special mark of attention, independent of the fact that "manure" too often

means raw stable dung, fermenting fast and reeking with ammonia, there is this to be considered, that natural manurial agents can only be satisfactorily taken by the fine hair-roots when presented in a very dilute state by the help of water. Moreover, the fermentation and decay of this organic matter gives off a large quantity of carbonic acid gas, filling up the interstices of the soil and driving upwards the atmospheric air which ought to fill them. Were it not that gases have a wonderful power of diffusion and dilute themselves away with great rapidity, the custom of bottoming tree-pits with fermenting dung would have been dropped long ago as a sure means of asphyxiating the roots. If the soil is of average fertility and well prepared, or if being somewhat poorer, a little old well-rotted manure has been added during the trenching, there is not the least need for the manuring of the hole referred to.

As a general statement it may be said that orchard manuring is best done by top dressing, and turning the material into the upper tilth to be carried slowly by solution down to the level of the roots. It is a good plan to have a plan of the orchard in which the rows are plotted and the individual trees have their names entered. This will enable one to identify each tree—as labels soon become illegible and no reliance can be placed upon a vague remembrance—distinguish the qualities of one from the other, and enable him to gain a general knowledge of fruit trees. If supports are necessary for transplants, the best plan is to put in two stakes 14 to 15 inches distant from the tree and tie it to a cross-bar fastened horizontally from one to the other: a single stake driven in among the roots is objectionable.

When the trees have been firmly established, the condition of openness and aeration with free passages of moisture through it and away must be maintained.

The whole of the ground between and among the trees has to be kept in an open worked condition, not only because it would otherwise harbour weeds which would draw sustenance from the soil which belongs to the trees, but for another and important reason. An open pulverulent tilth at the surface is the best preventive of evaporation from the underlayers in which the roots lie and perform their functions. As soon as a hard continuous surface-crust is formed, the uninterrupted capillary attraction exerted by the interstices of the soil-particles draws the moisture of the lower strata up to the heated crust, where it evaporates as fast as it is transmitted. It is not long therefore before the feeding-bed of the roots under such surface-crust is far too dry for their proper functions, the growth of the root hairs ceases, and the tree begins to show signs of flagging. Matters cannot be set right, as some ignorantly suppose, by flooding the root-bed with water. As the water gets slowly away by percolation, most of it is evaporated from the surface and the crust reproduced, with the inevitable result of the same capillary rising of the very water just administered and its dissipation into the air. There is therefore a pernicious alternation of a fast and feast forced upon the roots. The

true remedy consists in interposing a loose powdery or fibrous stratum several inches thick between the layer of soil in which the roots live and perform their functions and the external air ever greedy of moisture. And there are two ways of doing this.

THE MANURING OF PADDY.

Report on the proportions in which Bood Mixed Thomas' Phosphate Powder and Sulphate of Potash may be used as manure for paddy.

I propose to base my calculations on the results obtained at the Bardwan Experimental Farm for years 1894 and 1895. The following is a tabular view of the experiments:—

QUANTITY OF MANURE PER ACRE.		OUTTURN PER ACRE.				
		1893—1894		1894—1895		
Mds.	S.	Grain	Straw	Grain	Straw	
		lbs.	lbs.	lbs.	lbs.	
1	Cowdung 150	8	3641	4388	3291	4287
2	Unmanured —	—	1343	1714	1330	1577
3	Castor Cake 6	0	3334	4114	3195	4251
4	Cowdung 150	0	4443	5691	3845	5279
5	Unmanured —	—	1646	3291	1467	2743

9	Bone-meal 3	—	4690	6308	4673	6377
10	Saltpetre —	30				

I take the Indian maund to be equal to 9·8 gallons; i.e., a maund of water would weigh 98 lbs. equal measures of bone-dust, and of water would weigh about the same; so in round numbers I shall take the maund of bone-dust as equal to 100 lbs. and the maund of niter as about 111 lbs. Experiments 7 and 9 will be, therefore, when stated in lbs. per acre as follows:—

No. 7.

300 lbs. bone-meal per acre.

No. 9.

300 lbs. bone-meal per acre.

83 „ nitrate of potash.

The first of these (No. 7) would supply 10·5 to 13 lbs. of nitrogen and 70 lbs. of phosphoric acid per acre. The second (No. 9) would supply 21·3 to 22·8 lbs. nitrogen, 70 lbs. of phosphoric acid and 83 lbs. potash.

The following are mixtures containing the same amounts approximately of nitrogen, phosphoric acid and potash.

(1.) Corresponding to the 300 lbs. per acre of bone-dust, the following mixture might be used:

86 lbs. Blood-meal.

370 „ Thomas' Phosphate Powder.

(2.) Corresponding to 300 lbs. bone-meal and 83 lbs. nitrate of potash:

163 lbs. Blood-meal.

370 „ Thomas' Phosphate Powder.

66 „ Sulphate of Potash.

As a certain amount of nitrogen in the form of nitrate is regarded as of special efficiency to

rice in the earlier stages of its growth, it is found desirable to have nitrogen present in two forms (according to some authorities) a more soluble form, say, nitrate of potash and a less soluble form, say, blood-meal, instead of the last mixture, therefore the following may be used:—

(3.) 86 lbs. Blood-meal.

82 „ Nitrate of Potash.

370 „ Thomas' Phosphate Powder.

In experiment 7 in the table, the amount of nitrogen is a little over half what it is in experiment 9, while the bone-dust alone in experiment 7 contains about the quantity recommended in "The Farmers' Guide" for the manuring of rice. I am, therefore, of opinion that the increased yield in No. 9 is not necessarily due to the extra nitrogen, but may be attributed to the potash in the experiment.

I think, therefore, that the following mixture would give good results, more especially in cases where the soil already contained a fair amount of nitrogenous matter:

(4.) 86 lbs. Blood-meal.

370 „ Thomas' Phosphate Powder.

66 „ Sulphate of Potash.

In all these mixtures (1 to 4) I have taken 370 lbs. Thomas' Phosphate powder as the quantity containing phosphoric acid equal in amount to 300 lbs. bone-meal. I am disposed, however, to regard 370 lbs. as a maximum quantity, and it is possible that even 300 lbs. would be sufficient, when the greater availability of the phosphate powder is taken into account.

On upland peaty soils, rice could be grown without nitrogenous manure. On such soils 300 lbs. acid phosphate and 100 lbs. muriate of potash are said to give remunerative results. I am, therefore, of opinion that the following mixture would do even better on such land, the Thomas' phosphate powder tending to correct by means of its lime the natural acidity of such soils:

(5.) 300 lbs. Thomas' Phosphate Powder.

100 „ Sulphate of Potash.

100 lbs. sulphate potash does not contain so much potash as 100 lbs. muriate of potash does, but with the former there is considerably less loss by drainage through the ground than with the muriate, and, therefore, I think the sulphate would be practically equal in manurial effect, weight for weight to the muriates.

Another authority recommends the following manures for use in the cultivation of rice on new fields and on exhausted fields respectively: The figures are given in lbs. per acre.

New fields. Exhausted fields.

Sulphate of ammonia 89 178

Acid phosphate ... 222·5 356

Muriate of potash ... 44·5 80

In place of the above the following might be substituted:

New fields. Exhausted fields.

Blood-meal ... 150 300

Thomas' phosphate powder ... 222 356

Sulphate of potash ... 45 80

(Signed) M. COCHRAN, F.C.S.,
City Analyst.

ADHATODA.

THE AGRICULTURAL SCHOOL.

No. 10 of the Handbooks of Commercial Products (Imperial Institute Series) published by the Government of India, deals with *Adhatoda vasica* (known in Ceylon by the various names of Adathoda, Agaladara, Wanepala and Pavettai). It will be remembered that this is the plant concerning the insecticidal properties of which so much was written some years ago. These properties have now been fully discussed, and the various experiments made with the leaves to test their action on insects are referred to in the publication under notice. It will suffice, however, to quote the "conclusions" given at the end of the Handbook:—

The leaves of adhatoda are insecticidal in the same way as tobacco, but being a vegetable its effects are not so powerful as the alkalis and arsenites of the inorganic kingdom. Tobacco and its preparations decompose when exposed to the air, and their poisonous effects pass off after they have served their purpose in killing the blights. This is a great advantage over the use of such substances as London purple which are poisonous as long as they remain in a concentrated form, and, if left upon them, are likely to injure, sometimes fatally, the trees or shrubs. Tobacco is now almost abandoned as an insect destroyer by horticulturists, but it is feared adhatoda is not in a position to be a substitute for it. The experiments have shown that the plant is distinctly poisonous to certain forms of insect life, but the results so far as they have gone may be held as very possibly not justifying its extended use in tea gardens. In fact it is questionable how far insecticides of any kind are practicable.

The chemical analyses have revealed the presence of an alkaloid vasicine as the active principle, and this result has been confirmed by the physiological as well as chemical tests of Dr. Boorsma, of Java. A tartrate of vasicine is now an article of commerce on the Continent and future possibilities may be expected of it in medical science.

The abundance of nitrogen in the plant shows it to be worthy of the confidence placed in it by the native cultivators as a manure, and its fertilising properties are not confined to the organic matter, but are also due to the large quantity of mineral salts.

The opportunity is taken of thanking the numerous contributors who have assisted with information and experiments, and in elucidating certain features of one of the most ancient drugs employed in Hindu medicine.

Dr. Trimen thus refers to the plant in his *Ceylon Flora*:—Much cultivated by the natives as a fence. Largely grown about Jaffna as green manure for tobacco gardens. The Tamil name means that goats will not touch it. The juice of the leaves, also the flowers and bark, are used medicinally in children's coughs; the leaves are bitter, but have no scent when bruised. Hermann states that the bark was used to procure abortion, whence its name *Ecbolium*. The name "Malabar nut" is applied to it by the English in India—a name I have never heard here.

PRIZE DISTRIBUTION.

The prize distribution at the Agricultural School took place last evening, when the Acting Mayor and Chairman of the Municipal Council, Mr. W. E. Davidson, presided. The Hall where the prize distribution took place, and the passage to it from the entrance, were very nicely decorated with flowers, ferns and flags. At the entrance to the premises a pandal had been put up with an inscription welcoming the Mayor. Among those present were Messrs. J. B. Cull, S. C. Obeysekera, Dr. and Mrs. J. B. Drieberg, Mr. and Mrs. J. Drieberg, Mr. A. Drieberg, Advocate and Miss Drieberg, Mr. Jacob De Mel, and Misses De Mel, Mr. and Mrs. James Peris, Mr. Charles Peris, Mrs. Human, Dr. and Mrs. Asserappa, and Miss Asserappa, Mr. and Mrs. E. C. Davies, Mr. and Mrs. A. Y. Daniel, Mr. G. W. Sturgess, &c.

THE REPORT.

Mr. DRIEBERG, the Principal of the School, read the following report:—

It was only recently that a detailed report of the working of this Institution was made by me for the Director's Administration Report, and as there is little that I can now add to that document, I have not much to give you in the way of a report today.

I am frequently asked the question, "How many boys have you here?" and the enquirer generally takes it for granted that the spacious accommodation afforded by this building, which someone has remarked is the only site worthy of the future University of Ceylon, that all this luxury of space was monopolised by a handful of agricultural students. I would then explain to the visitor that the building known as the School of Agriculture harboured no less than four Schools, viz., the Agricultural School, the Forestry School and the Training School—the three working more or less independently of each other—and the Practising School which is affiliated to the last mentioned; while a large section of the grounds is in the occupation of the Government Dairy. I am glad to be able to say that the building itself which some three years ago was pronounced by the Public Works' Officer in charge to be in a dangerous condition, has been gradually renovated block by block.

The students of the Training and Forestry Schools have a more or less definite prospect of employment under Government, as teachers and Forest Officers respectively, but the boys of the School of Agriculture have not that advantage. It may be said that they are expected to pursue knowledge for its own sake; but that has not proved to be a sufficiently strong inducement in technical instruction in Ceylon. It was on this account no doubt that Government generously decided to provide students who go in for a course of training in mechanical engineering and the allied subjects, with certain openings for admission into its scientific departments, and it is to be hoped some such inducements, will also be held out to those who choose to study agricultural science, seeing that it underlies an art which so widely and deeply affects the welfare of the country. This is all the more to be desired, as the superior prospects of the present students

of the Technical College have been the indirect means of draining the sources from which Agricultural Students have been drawn.

In this connection I should like to read to you a passage from the Resolution of the Government of India on the Report of the Bengal Agricultural Department for 1896-1897. It runs as follows:—"The Agricultural Conference held in Calcutta in 1896 recommended (1) that the course of study in primary and middle schools should be so revised as to include a graduated series of lessons in agriculture and in other subjects of Elementary Science; (2) that agricultural classes should be opened in connection with Sibpore Engineering College; and (3) that a certain number of appointments in the Public Service should be reserved for those who have received an agricultural education. Sir Alexander Mackenzie accepted these recommendations. The sanction of the Government of India has recently been received to the opening of the agricultural classes at Sibpore, and the details of the scheme which will soon be published for giving effect to all these recommendations of the Conference are now being worked out. There should therefore be a hopeful outlook for agricultural education and agricultural reform in India, and if a similar "resolution" of the Governor of Ceylon be passed, we of this institution will have good cause to congratulate ourselves and set to work with better cheer; for the result will be that a number of students of fair intelligence and respectability will be drawn to the school each year, and that the teachings of modern agriculture will find in them a good nidus and eventually leaven the whole mass of our rural population.

Suggestions have come from different sources, but agreeing in the main, for giving agricultural instruction in Ceylon a more practical turn, and these will no doubt receive full consideration at the hands of the Commission, which, it has been announced, is dealing with the school, and which we must sincerely hope will succeed in formulating a scheme that will be more fruitful of good results than the present routine of work has been.

Of the financial condition of the Dairy Farm and Model Farm I have a good account to give. The gross receipts of the Government Dairy alone for the year should not fall below R19,600, those of the grass lands attached to the Dairy ought to exceed R3,000, while for the Model Farm I put down the gross receipts at over R4,000. The profits, after deducting all working expenses, rent, &c., from these three sources, will be between R5,000 and R6,000.

The Dairy was started in 1893 with a vote of R19,522-12 from Government, but later on it was found necessary to procure an advance of R11,500 in order to meet the losses resulting from an outbreak of cattle plague and also to meet the demand for a sum of R4,400 as compensation for acquiring the lease of the Model Farm. Of this advance the Dairy has been paying back over R7,000, and the balance due about R4,000 will be easily met this year. Against the capital of R19,000 odd must be placed a sum of nearly R9,000 credited to revenue in 1893 and 1894. So

that the position of the Dairy, at the end of this year, may be roughly sketched out as follows:—

Capital cost	R10,000
Cash in hand	2,500
Value of stock, &c. ...	12,000

This, I think, may be considered satisfactory, and if the Government decides to dispose of the whole concern the capital cost will be cleared by the sum realized.

The experiment in vine growing, which attracted considerable notice while it lasted, terminated at the end of one year for which period it had been originally arranged to make the trial.

We have now made a small beginning in apiculture, and I would draw attention to the new hives on the premises, for the designing and construction of which I am indebted to Mr. Chas. Andree of Kurunegala.

The *Agricultural Magazine* still continues to appear regularly every month, having now had a continuous life—by no means common in the history of Ceylon Magazines—of over 9 years. The Magazine, I can assert, has done good work in the cause of agricultural education by bringing much useful information before the public, and it now travels to most parts of the world, both independently and in company with the *Tropical Agriculturist*, while it serves as an exchange for all the important agricultural journals and papers published.

I stated at the outset that I had not much to give you in the way of a report this evening, and I will therefore conclude by thanking my assistants both in the Schools and Dairy and Model Farm for their co-operation, thanking you, ladies and gentlemen, for the kind support which you have given me by your presence here today, and last but not least thanking you, Mr. Chairman, for the honour you have done us in presiding on this occasion.

The prizes were then distributed by the Chairman, Mr. Drieberg calling out the names of the prize winners, who were the following:—

SENIOR CLASS, 1896.—Proficiency in Agriculture: C. E. Wickremeratne, (he was absent being employed as an Agricultural Instructor, and the Chairman testified to the good work done by him at Balangoda). Proficiency in English and Mathematics: C. E. Wickremeratne.

JUNIOR CLASS, 1896.—Proficiency in Science: W. R. De Silva; Proficiency in English and Mathematics: W. R. De Silva.

SENIOR CLASS, 1897.—Proficiency in Agriculture: A. R. Jeremiah; Proficiency in English: G. W. De Saram; Proficiency in English and Mathematics: D. C. De Silva; Proficiency in Science: J. E. Fernando; De Soysa's prize for Agriculture: E. R. Jeremiah; Prize given by the Manager of the Dairy, for proficiency in Dairy work: E. R. Jeremiah.

SCHOOL CERTIFICATES, 1896.—First class, C. E. Wickremeratne; second class, D. J. Dassenayake.

SCHOOL CERTIFICATES FOR 1897.—First class, E. R. Jeremiah; second class, D. W. De Saram.

Mr. B. CULL, the Director of Public Instruction, was the next speaker. He said, that there was an old proverb which many of them knew which ran to the effect that the cobbler should stick to his last. He felt that in addressing a

meeting of gentlemen—students more especially—some of them cognisant with agriculture, he knew nothing about it, but responsible as he was to some extent he supposed he must say a few words, but he could assure them that they would be very few. He was glad to hear from Mr. Drieberg's report that in spite of the paucity of numbers good work had characterised this last session of the year, and that good work had been attested by the recent examination held, manifestly showed that the work had really been good. For his own part he had always regretted and still did regret that more interest in the Agricultural College was not shown by those who ought to be interested in it. It started with very good beginnings and numbers, and was supposed to appeal to a special class of people, those who were more particularly interested in agriculture, especially land owners and the like, and general promises of support were held out. These promises had not been fulfilled. He thought it was a pity. He believed that boys who had been sent from the College during the few years of its existence had sufficiently shown that they had learnt what they ought to learn at the College and carried this knowledge out in practice. One special instance he learned the Chairman incidentally refer to during the prize distribution was the case of the Agricultural Instructor working at Balangoda. His work he (the speaker) could speak from personal experience showed very ample and satisfactory results. If more students were sent to the College more could be done by the College. But if landowners failed to redeem their promise, or failed to perceive the utility of the College, numbers must fall off. Another point to which special attention might be directed was that there was too much of a general idea—merely a casual idea gained without any sufficient information at all—of criticising the College as very expensive, a College consisting of only a few boys, half a dozen or so, and not worthy of support. It was so easy to write generalities of this kind, so easy to write without special knowledge. In the Superintendent's Administration Report he referred to at least five schools carried on in these buildings—the Agricultural School, the Forestry School, the Training School, the Practising School and the Veterinary School and there was also Dairy Farming. It seemed to him that most people were very hard to satisfy when they did not think that that represented a fair amount of work to be undertaken with a fair amount of success achieved. They must bear in mind that the school did not consist of half-a-dozen students. These were only one item in the mass. The school embraced other classes all of which were doing good work, so he was informed by those responsible for the work. If that was more generally recognised there would be less captious criticism as to the usefulness and maintenance of the school in its present status. Mr. Drieberg mentioned the bright prospects that had been opened up recently by the newly-established Technical School. Undoubtedly he thought that the Technical School had really a bright prospect before it, and he did not see why similar prospects should not in the hereafter extend to the various branches of this school as they became more widely known.

At any rate even admitting that the School of Agriculture is at present small in numbers, still it had been supplemented by the other schools which he had mentioned to them: notably the Veterinary School and School of Forestry, in which good work was being pursued. With regard to the Veterinary School two boys had been sent from the Colombo school to receive full instruction in the Veterinary College in Bombay. He was looking over the papers only a few days ago in regard to one boy who had since returned to the island. He found in the report of the Principal of the College at Bombay he spoke most highly of the work of this student. One paragraph that specially struck him was that for his own part, in case the student failed to obtain employment under the Government of Ceylon he (the Principal) would be only too glad to enlist his services on behalf of the Government of India. (Applause.) This was as good a proof of what a boy was worth as they could want to have. Coming back to the School of Agriculture and the possibilities of usefulness that ought to attach to it, it was only last week that he received a letter from the Government Agent of the North-Central Province in which he expressed his wish to attach to all Government schools in the Province about an acre of land to be planted with economic products, to be taken charge of by the head teacher of the school and also by the boys. Their interest and work were to be enlisted in the enterprise. It seemed to him to be a very good idea of utilising some of the agricultural students where they could be utilised by appointing them to districts where Revenue Officers or those in charge took an interest in the practical work that was being carried out. For his part he always thought that one of the chief agencies that led to the decrease in the Agricultural School was that there was not sufficiently direct influence or supervision over the school. There was a dual responsibility—the responsibility of the Department and the responsibility attached to the Revenue Officer. Neither of them were practical responsibilities, and so they to a certain extent became evanescent. In the case of such gardens he wrote to the Government Agent pointing out that many economical foods could be cultivated in districts where they were now neglected, by their treating such simple foods as yams, sweet potatoes and more especially betel. He had been amazed to find that the bulk of the betel sent upcountry was grown in villages a few miles from Colombo. Large supplies were sent day by day, and with the exception of a few places he had seen the supply of betel was mostly obtained for the higher districts from these two or three low-country districts. He believed the betel vine was capable of cultivation, if not in the higher altitudes at least in the lower ones, and seeing that betel was not a luxury but a necessity, it should be encouraged. (Applause.) He understood the Mayor was going to make an elaborate speech on sanitation, and he would not keep them further from the promised treat.

SUGGESTION OF A UNIVERSITY.

THE CHAIRMAN said:—It is a pleasure to me to preside at an annual prize-giving of the Agricultural School. It recalls to me the glowing enthusiasm of my friend, Mr. Green, to whom it

owes its birth. It is a pleasure to me to be associated with your Principal, with members of whose family I had lived on the pleasant terms for many years. I have, too, a double interest in schools, having been both a schoolboy and schoolmaster. A schoolmaster I was—earning a hard living at a younger age than most of the students who are present today. I always look back to that time with pleasure. It was the hardest work I ever had, for I was teaching others all day and myself a good deal of the night. There are those who argue that the Agricultural School, as a training school for agricultural students, seems likely to fail in its object because it cannot attract students without adventitious aid. Students only came because the fees were low and because they hoped that special prizes would be offered, and that were these inducements withdrawn, students would cease to be attracted. Why, of course, no school will attract students without offering some special attractions. But the reply is—an agricultural training school is founded no doubt to meet a special demand for that form of education. I used to discuss the question with Mr. Green who had a two-fold idea:—To spread the teaching of agricultural science among the peasantry through the agency of trained teachers from this centre in the Government village schools. The other idea was that gentlemen farmers—a most neglected illiterate class in this country—should send their sons here to pick up Western ideas. This was bound to fail from two causes, first, where the class of embryo agricultural school teachers came the sons of wealthy people would not come. The parents preferred a literary education because it sounded better and because the boys mixed with their equals. It was impossible to cater for both classes at the same time. But there was, and is still, this still more fatal objection. An agricultural training school, such as that at Cirencester is an excellent institution, but only under the condition, *i.e.*, that the students shall be sufficiently advanced in primary education before they enter such a class. It is specialising in knowledge and should be wholly apart from the rudiments of general knowledge. It is only wasting the time of the teaching staff if there is not this foundation to work on. The foundation is a sound elementary, commercial education in English:—A decent Board school curriculum, or better still, the learning to be got at a Scotch parish school. Your fundamental error here is to try to build on a defective foundation. Were I king, I would ordain that all boys in Colombo should be taught rather to a certain age, 14 or 15, or up to a certain standard in the English language and in reading, writing and arithmetic. Under our present voluntary system, one-half at least of the boys of Colombo get no education at all, and the rest, when they ought to be grounded in elementary subjects, are being taught to acquire a glimmering of special culture when they are mentally still unfit to assimilate the knowledge. A very fair illustration occurs to my own knowledge in connection with this School Magazine. Ceylon is essentially an agricultural country, although I see a dozen reasons why Colombo should also be a manufacturing centre. Well, it is for the present an agricultural country. I contributed not long ago

to the "Agricultural School Magazine" a paper on an agricultural subject in order to elicit criticism on the facts and figures which it had taken me years to collect. Six newspapers turned the stuff into leading articles and indulged in guarded generalities. But although the subject was one which must be vitally important to very many trained students, and to gentlemen farmers; and although I purposely quoted figures (not my own) which must have struck any reader as abnormal, not a single criticism ever appeared either in the magazines or in the six newspapers. You may call that Oriental apathy. I am inclined to hold that it is a direct result of the Ceylon system of education. An unhealthy Strasburg system of gathering up just a portion of all the chickens. And now I come to my deduction and the conclusion which has a special bearing on the future of this school. All boys of Colombo should be taught the English language and the rudiments of a commercial education, Reading, Writing and Arithmetic. They should be at School from 8 years until they have passed the Vth Standard of a Board School, or until they have attained 15 years. The rate-payers should elect their representatives by Wards, and each Ward should either arrange with the great Educational Societies to provide this elementary education or should apply to the Municipal Council for the establishment of a secular Board School. It is quite possible that this could all be arranged without an addition to the direct taxation; although Colombo rate-payers should bear in mind that their rates are only half of those in some other eastern cities, and only one-third of what I have to pay at home. At the end of this free course of elementary education, 90 per cent of the boys should straightway go and earn their living. If they care to read then, they can go on educating themselves till they die. We will give them opportunities to do so. If they don't care to read and go on, they can do without. They may forget what they have learnt and be none the worse for it. But they will have had their chance—which they have not now—and that is a chance which should be allowed to all free men under the principles of English rule. There will remain 10 per cent or so: either the sons of wealthy parents or boys of exceptional promise. Those who are destined to have a superstructure raised on the sound foundation thus laid in their mind will at the age of 15 or 16 matriculate at the University of Colombo. The University of Colombo—where all the higher education will be imparted—will raise a stately noble architectural triumph on the site where we are now assembled. Situated in the central of the wealthy suburbs of Colombo, it will be most convenient for the purpose. It will be a teaching, examining and residential University. The cluster of houses—Colleges we may call them—grouped round the University buildings would bear the time-honoured names of the Educational History of Ceylon. St. Thomas' College would be there, and the Royal, St. Joseph's, St. Benedict's perhaps: perhaps Trinity for the Kandians and perhaps Gogerly House to represent the time-honoured name of a revered disciple of Wesley. And I have my eye on a big new house, not far off, for an ideal home for the

Newnham of another clime. But, visions apart, what benefits has this new development of this site to recommend it? I will briefly enumerate them:—(1) The University will provide lectures in Letters—Litt: Hum: in law: in Medicine, in the applied Sciences: Engineering, Surveying, Electrical Engineering, Forestry, Agricultural Science. (2) All the teaching strength of Colombo—which is dreadfully wasted as it is,—would be concentrated for the benefit of all—and there would not only be a great addition to the strength of the tutorial staff, but there would be a great economy in the cost. You would have a better service cheaper. Think how strong the tutorial staff would be with the pick of Wesley, the Royal, St. Joseph's and St. Thomas', this school and St. Benedict's combined. Many others of us would be glad to offer our services: imagine how much more efficient would be the exercises of Mr. Brown, Mr. Human, Mr. Barnard, Mr. Templeton and many others, who now have to work with what material they can pick up. Many others of us would help. I for one would gladly serve under the classical tutor as a lecturer in my hobby—English literature. Then, again, there is the social side. The old schools would still be gathered in friendly rivalry, with better knowledge of each other, more chance of mutual improvement, with far finer playing fields, and without the ragtails and bobtails, who now spend years at the schools without learning anything. Think of the advantage to the law students and medical students to be kept in hand and nursed in the tradition of a University, instead of being scattered about without cohesion or a local habitation. This too would be a solution of the problem which the Government has to meet in regard to appointments. When the class lists come out every year, the prize to the winners in the classical and mathematical sides would be University scholarships of £100 a year for three years at Cambridge, with the option of a local cadetship on taking at least a second class at Cambridge. Another English scholarship of £100 would go to the first in the Science Schools, for a three years' course at Cooper's Hill to be followed—after a satisfactory final examination at Cooper's Hill,—by a nomination into the Public Works Department. Other well placed lads in the Science side would get posted to vacancies in the Survey Department, in the Railway Workshops; in the Municipal Electrical Department. The first in class should have a scholarship of £50 a year to help him on at the Bar Examinations in England. Similarly, those in the Forestry and Agricultural Schools at Dehradun would earn scholarships to be followed and supported on good reports. There would be a regular examination held at stated intervals—once a year—just such a central test as should satisfy the Government: and we would all—I mean all of us who have thrown in our lives with Ceylon, whether we are born here, or who merely come to live and die here, or who totter home to rest a few years in England—we would all be proud of our University at a city where alone throughout the East I believe such a University to be possible; and my friend, the Superintendent of the School of Agriculture, would make a first-rate Bursar, as well as lecturer, and he and I would put our heads together and see how we could manage

to run it at a cost to the Government, and to the Government Educational Societies, at not more than they spend now to less purpose. Thus and thus, ladies and gentlemen, would I do were I King of Utopia.

Mr. S. C. OBEYSEKERA was the next speaker. He thought Agriculture was one of the most honorable industries that a man could occupy himself with. He condemned the captious critics who ran down the Agricultural School, which was one of the best things that Government had given to the people. It was one which the Government had given for the greatest good of the greatest number. If the speaker had been able to avail himself of the agricultural training that was imparted in this school, he would have been much better able to discharge the functions of a landlord, than at present, and with more satisfaction to himself and the labourers under him. Ceylon possessed in an eminent degree, land, labour, and the capital for agriculture, but the only want for the improvement of this industry was scientific knowledge on the subject. This was a subject necessary to be seriously considered for the improvement and advancement of the masses of the population. Criticising the School on a commercial basis was an act of suicide and deserved the greatest censure. The Government which was a paternal one did not require profits as in a commercial undertaking. The profits and returns of the expenditure incurred, would be the amelioration of the people. The amelioration of the people and the improvement of the industry should be carried on through the medium of the school, and it was no matter whether there was an annual loss of £600, or even a thousand or two. This education should be supported by the Government for the good of the people. It was a recognized policy with the Eastern Kings, to devote funds for the improvement of agriculture without considering its returns. Why was it? Simply for the amelioration of the condition of the people. He then touched on the works done by King Panduwas in Pihitirata, followed by Kings Dhatusena and Prakramabahu. Visitors to the parts of the Island where irrigation works had been carried on by Sinhalese Kings, would be surprised to see what amounts must have been spent on them, for the improvement of agriculture. Were they reproductive works on a commercial basis? The same was the case during the Dutch Government under Governors Flack, Vandergraes and Van Eyck. As an instance he pointed to the Mulleriyawa tank, a few miles from Colombo. He was sure that all would agree with him that the Agricultural School needed only encouragement, and he maintained that its existence should be hailed by everyone.

Mr. Advocate JAMES PERIS was the next speaker. He said he had been asked to move a vote of thanks to the Chairman. He was sure that every one would agree, that the selection made by Mr. Drieberg for the Chairman was an excellent one. The Chairman had taken a great interest in the people of Ceylon, since the day he had landed in the Island. He had taken a great deal of interest in his official and private capacities, in agriculture and education in the Island, and his interest in these subjects was evident from the educational scheme given by him

that day. His scheme deserved the serious consideration of all. It was time, the speaker thought, that they had a University at Colombo. The number of colleges and schools now existing could be concentrated to form a University. He was glad to see a passage in the report boldly suggesting to Government to improve the prospects of the agricultural students, as was done in the case of the Technical school students. This was a very good suggestion, and shows the interest he took on the subject, very few acquire knowledge for its own sake. Even in England it was the same, except that a very few, who were wealthy, who pursued knowledge for their improvement only. Good opportunities should be put forward for acquiring knowledge on special subjects. He then stated that the native Headmen, especially the Chief Headman, should acquire knowledge in agriculture. He was sorry to say that in the case of some Mudaliyars and Muhandirams of Korales, they were deficient even in their mother language. Such men should not be entrusted with the duties appertaining to Chief Headmen. He suggested that these Headmen should be given an agricultural training on scientific principles in this school. If they possessed such a knowledge, the people and the agriculture in the Korales under them could be greatly improved. He was sure that this was matter deserving serious consideration. He had great pleasure in moving a hearty vote of thanks to their Chairman.

Mr. ALLAN DRIEBERG, Advocate, seconded the vote, and it was carried with applause. On the call of Mr. Drieberg, three cheers were then given for the Chairman, and the proceedings closed. The Volunteer Band, which was present, then played a few selections of music, light refreshments being served to the visitors.

GENERAL ITEMS.

Numerous experiments and investigations, including the cultivation of crops under careful observation by practical men, have resulted in general belief and acceptance of the following facts which may be turned to practical account: (1) That leguminous plants well furnished with root nodules will collect and store per acre the nitrogen supplied by several hundred pounds of guano, nitrate of soda or sulphate ammonia. (2) That when the spores of the bacteria are distributed in the soil and taken up by the root hairs of the plants, these spores induce abnormal growth in the tissues of the roots and increase to many millions of organisms in a short while. (3) A soil may contain some of the bacterial spores and therefore there may be no nodules formed. And as each variety of leguminous plant appears to be the host of a special bacterium, it is quite possible that the one required may not be present to invest and form nodules on the crop; so that in both cases there would be no nodules or collection of nitrogen. To provide the proper bacteria in the soil, a mode of soil inoculation has been adopted. A small quantity of soil from a field in which a good crop of the special legume to be cultivated has been grown is spread over the new land.

The system of planting fruit trees in holes is much condemned. An authority on orange culture says:—I have found few places where fruit trees can be planted with any hope of success in holes. In a clay soil or clay subsoil planting in holes will be as bad as planting in an iron pot, and I have no doubt that the dying back of comparatively young trees and the yellowing of leaves must be attributed to that old system of digging a hole in the soil as hard as a sheet, planting the tree and filling the hole with water. The ground should be prepared by ploughing and subsoiling as deep as possible—say 18 to 24 inches—during the rains, and the clods broken up and the land levelled before planting.

A well-tried cure for the poultry scourge, contagious "roup" as it is called, though the disease is more probably typhoid in character, is to get a tub of warm water, add a disinfectant such as carbolic acid or other coal tar by-product, and with some soap give the bird a thorough good washing, dry the feathers and place the bird before a good fire.

Citronella oil which is extensively used in perfumery and for other purposes, is chiefly obtained from Ceylon and Singapore. It has been noticed for some time that the native-distilled oils have an aroma much inferior to those distilled by Messrs. Fisher of Singapore and Messrs. Winter & Son of Galle, and that these two classes of oils also show marked differences in physical characters. Messrs. Umney and Swinton have lately examined a number of commercial samples of both classes, and their results were communicated to the recent British Pharmaceutical Conference. In the case of the native oils, submitted to distillation, a residue amounting to 37 per cent of the total was left behind, while the whole of the oil from English forms distilled over. This difference was thought to be due to the fact that the latter were steam distilled and the latter obtained by fire heat. The residue referred to was distilled, after purification, between 245° and 280°c., and had a high specific gravity, possessing all the properties of a sesquiterpene, but differing in physical properties for any previously-described bodies of that class. Being odourless it is considered a valueless constituent, while being fairly soluble it affects the solubility of the oil. Again, it was found that while camphene was almost entirely absent from the native oils, the oils of the English firms consisted chiefly of camphene, the active terpene of the native oils being absent, owing probably to its having been removed. The chemists therefore conclude that the native-distilled oil is in no way sophisticated, but is a genuine natural oil. [It would be interesting to know (1) whether the natives use [any other grass other than, or in addition to, the true citronella grass (the cultivated form of *Andropogon nardus*), and (2) whether any difference as suggested in the above report is the methods of distillation by natives and Europeans. Some years ago it was pretty well known that a good deal of adulteration with kerosene oil was practised by the natives. Has this practice been given up now, or have the manufacturers found another adulterant which chemists are unable to identify?]
